The distinguishing feature of the method is the way in which the opening is begun. The futility of making a blast without first weakening the substance by extricating the cone section can easily be understood. When this is done, the rest of the operation may be manipulated with comparatively little difficulty.

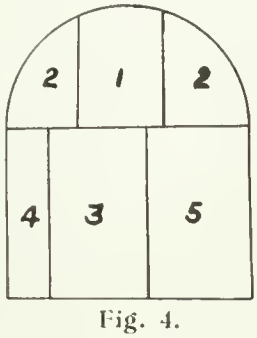

Fig. 4.

Tunneling Through Soil.—The engineers of different countries seem to have contrived methods by which every kind of loose structure may be successfully treated. In most respects the following methods are very much the same; the Belgian, English, German, Austrian and Italian differing only in the order in which the drifts and headings are excavated, and also in the different frame structure employed. The Belgian method consists of putting forward the arch before the walls are built; while in the German method the perimeter is excavated and lined before the core is removed. In types such as the English and the Austrian the whole fissure is excavated before the lining is placed, although, however, the excavation is never far in advance of the masonry work. The Italian method consists of excavating the lower half, lining it and filling it in again, followed by the work of excavating the upper half.

Submarine tunneling is perhaps the most expensive, and seems much more difficult than any of the other soft-ground tunnels, particularly in the case of tunnels which are constructed at small depths below the water bed. There is always a danger of flooding, and the materials encountered are extremely difficult to handle. Various methods are used, some of the most important being the shield method, the compressed air method, and when we come very close to river bed we use the cofferdam method, and pneumatic caissons.

The shield method is very interesting from a historical point of view. It was invented by Isambardt Brunel, a French engineer, in the early part of the 18th century. The Frenchman was gifted with a keen sense of observation. While cruising, he happened to observe the ingenious method of the ship worms in working their way into the wood. He noticed that as the animal bored its way in it applied a secretion which lined the opening and rendered the lining waterproof. Being an engineer, the idea intimated itself very strongly to his mind in connection with submarine tunneling. He immediately set to work to contrive a mechanical device which would give the same result as the boring of the small insect, and finally succeeded by inventing his universally known boring machine.

The invention consists of a circular boring disc placed immediately in front, which might be termed to represent the head of the insect, while the body is cylindrical in shape and constructed of steel in the form of a shell. In operation the earth is conveyed out and the tunnel is lined with steel tubing immediately in the wake of the boring machine. In this way it is kept perfectly water-tight, eliminating the possibility of cave-in, and making the otherwise difficult task into a comparatively simple operation.

HEWN OUT OF ROCK.

A peculiarity of the New South Wales Government dockyard on Cockatoo Island, in Sydney Harbor, is that it is hewn out of solid rock Historically, Cockatoo Island is of much interest, as it was the site of a large prison in the days when British convicts were deported to Australia. The present offices on the island are in the old prison buildings, the stone walls, barred windows, and iron-doored cells being still in evidence.

The formation of the island was originally quite unsuitable for a dockyard, as the solid rock rose sheer from the water to a height of 60 to 70 feet. By using convict labor, however, the rock was gradually cut back, first, to permit the building of graving docks, and later to make room for building slips and shops near water level. The work has been continued until at present two-thirds of the total area of thirty-three acres has been brought to a practically uniform level of about 15 feet above high tide.

When a beam of X-rays is passed through thin, rolled metal sheets to a photographic plate placed parallel to the sheet, H. B. Keene, of the University of Birmingham, finds that these patterns are of two classes, in one of which the central spot produced by the direct beam is surrounded by an irregular halo of smaller spots, while in the other the patches around the central spot are extended and form a faint but perfectly symmetrical design. The figures vary with the metal. Markings of the first kind are produced by metal sheets that are either well aged or recently annealed, and the symmetrical patterns are given by newly-rolled sheets. The spots are due to reflections from the micro-crystals within the metal; the symmetrical patterns are formed by the structure imparted to the metal by the rolling. Annealing a newly-rolled sheet changes the pattern from the second to the first class, and rolling an annealed sheet gives the reverse change.

WATERWHEEL GENERATORS

WATERWHEEL generators have recently been built to conform with the rapid development of hydraulic power for driving electric generators. The increased demands for such service require almost infinite combinations of capacity and speed range. Refinement in the design of both generators and waterwheels has made these changes possible; the successful operation of many high-voltage transmission lines and

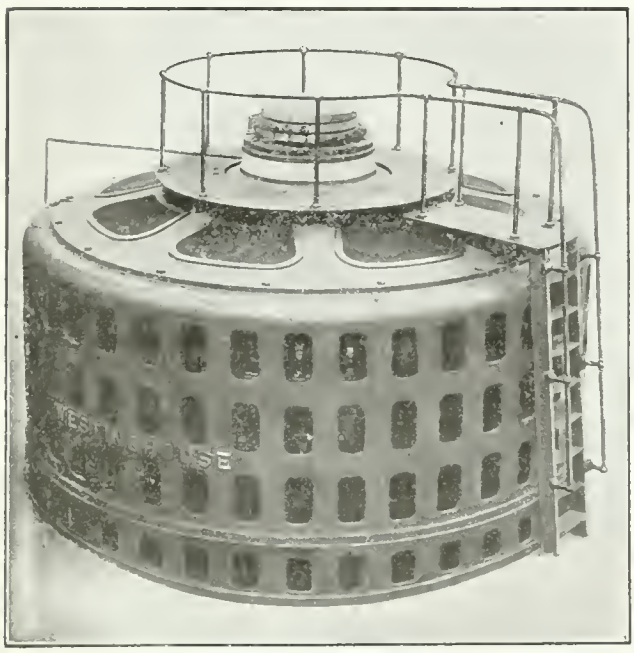

Fig. 1.—A 12,500-Kva., 6,600-Volt, 50-Cycle Generator Complete.

the ever-increasing demand for power, all aid materially in the utilization of many water powers heretofore considered either impracticable or inaccessible.

Two types of waterwheel generators are built—horizontal and vertical—depending upon the local conditions in each case.

Horizontal Type.—The standard horizontal unit is of the two-bearing, coupled type construction; that is, the generator includes shaft, two bearings, and a bedplate usually designed to allow for sliding the stator to one side in case ready access to either the stationary or rotating winding is desired. The stationary frame is made of a strong, rigid iron casting, into which soft steel laminations are dove-tailed and securely fastened.

Ventilating ducts are spaced at frequent intervals across the face of the armature punchings, allowing for perfect ventilation to all parts of the active material.

Form-wound, interchangeable armature coils fit into parallel open slots punched in these laminations, and these coils are held firmly in place by means of fibre wedges. The coils are insulated and impregnated with fabrics and compounds of high insulating qualities.

No single type of construction will meet the varied requirements in rotor design, therefore several well-tested methods are employed. When comparatively low peripheral speeds are encountered a cast-iron spider with bolted-on, or dove-tailed poles, is usually employed. For higher speeds cast steel, or steel plate construction may be used. In the case of very large relatively high-speed machines, the difficulty of securing perfect castings may lead to the well-proven laminated rim structure.

All field poles are made of thin steel laminations riveted together with overhanging pole tips provided to support the field windings.

Field coils are wound of heavy copper strap on edge, insulated in such a way that each individual turn is exposed to the ventilating air, and thus perfect radiation results. The coil is securely fastened between the rotating spider and the tips of the field poles by heavy coil supports.

All parts are carefully inspected during each step in the process of manufacture, and before the succeeding operation is started. When completed, the machine is carefully tested under conditions as nearly identical as possible to those which its future service will demand.

Vertical Type.—Westinghouse standard practice recommends that the generator be fitted with two guide bearings which are supported by brackets fastened to the stator frame. Also, a bedplate or pad on which the stationary part rests.

The roller, or thrust bearing, which supports the weight of the revolving part, may be mounted on top of the generator frame, between generator and turbine, or

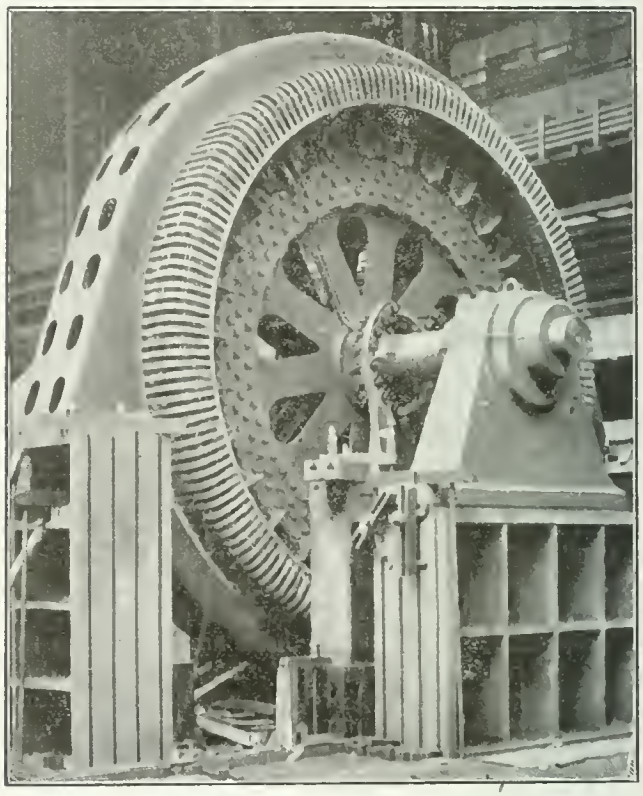

Fig. 2.—A 9,375-Kva., 6,600-Volt Unit, in Shop Testing Rig.

underneath the turbine. In case it is mounted on top of the generator frame, this frame must, of course, be made heavier and more expensive than in cases where it has only to support the stator punchings, winding and guide bearings. Wherever placed, this bearing usually supports not only the rotor of the generator, but also the turbine runner, and in addition takes care of any unbalanced water thrust.

A rigid cast iron frame, into which soft steel laminations are securely dove-tailed, forms the basis of the stator.

Form-wound, interchangeable armature coils are held in open slots by means of fibre wedges. The coils are vacuum dried and impregnated before the outside insulation is applied. This outside insulation consists of wrappings of paper and mica on the straight portions of the coils which lie in the slots, and servings of treated cloth over the V-shaped coil ends. After the outside insulation is applied the coils are treated with an insulating varnish which renders them moisture and oil-proof. An insulating coil is provided in each armature slot to prevent abrasion of the coil and a fibre wedge holds coil and cell firmly in position.

In case of failure of a waterwheel governor to act, the rotating part of both waterwheel and generator are subjected to unusual stresses, due to the overspeeding of these parts. The rotors here illustrated are designed for the maximum obtainable speeds which result in such instances. These overspeeds vary from 50 to 100 per cent. Due to the wide range of speeds encountered, no one type of rotor construction will give ideal results.

There are several designs of rotors, each one particularly well adapted for the requirements for which it is used. Comparatively low peripheral speeds may permit the use of a cast-iron spider with either bolted-on or dovetailed poles. A higher speed generator may demand an entirely different construction. For such work cast steel or rolled steel plates are often employed. In case of very large machines, it may be difficult to obtain perfect castings, and here the well-proven laminated rim may be employed.

Field coils are ordinarily wound with heavy copper strap on edge and insulated between turns with asbestos. This construction is particularly well adapted to give perfect radiating qualities, and because of the heavy strap used is practically indestructible. The coils are securely fastened between the rotating spider and projecting tips of the field poles by heavy coil supports.

Waterwheel generators of almost any practical capacity or speed for installation in the smallest isolated plant or the largest hydro-electric generating station have been furnished by the Westinghouse Electric and Manufacturing Company.

It is noticeable that the value and conservation of cheap fuel and power in the United States are being more fully appreciated each year. When it is borne in mind that coal in the States of Illinois, Ohio, Pennsylvania, Virginia and Alabama during the year 1910 averaged in price $1.08 per short ton at the mines, it will be better understood why these States occupy such prominent positions in the industrial world. The cost of transport in these States is not a serious item, for the cost of bituminous coal, according to quality purchased, ranges from $1.50 to $3.00 per ton, f.o.b. New York harbor. Coal in large quantities can be had in Pittsburg for $1.00 a ton, but even in remote parts of the above-named States the cost averages under $3 per ton. The supply of natural gas was at one time abundant and cheap, but extravagant waste has led to serious depletion and increase in price. Water power has been developed in some of these States, with the result that the cheap electrical power which is available, has contributed considerably to the development of the country around. As already stated, the movement in the United States towards the utilization of poor fuel is becoming stronger each year, and the result is the establishment of power plants where formerly it was not thought possible, and this is opening out new industrial centres to the advantage of all concerned.

NEW METHOD OF COOLING GAS ENGINES.

ORDINARILY about 30 per cent. of the heat value of the fuel passes from the hot gases to the cylinder walls and pistons, states Prof. Bertram Hopkinson, in a paper read before the Institute of Mechanical Engineers, at Cambridge, describing a new method of cooling the cylinder and piston of gas engines. In order to prevent the overheating of these parts under test conditions, it is necessary to provide a water jacket around the cylinder, and, in the case of large engines, to circulate water through the pistons and around the exhaust valves. Most of the disadvantages under which the gas engines labor are due directly or indirectly to this fact. The complicated and thick-walled castings required for the cylinders are apt to crack under the influence of the wide variations of temperature, and overheating of deposits on the internal walls of the combustion chamber causes pre-ignition, so that it is not always practicable to work a gas engine continuously at its maximum output.

The idea of introducing water into an internal-combustion engine is not new. It is a common practice in oil engines to introduce water along with the oil in order to permit the compression to be raised, and water has been injected into gas engines for the purpose of preventing pre-ignition. Proposals have also been made to introduce water for the purpose of cooling parts of the metal. None of the latter, however, have been practical, if indeed they have ever been more than just proposals on paper, apparently because their originators did not appreciate the conditions which must be satisfied with the injected water to act as an effective cooling agent. If the water be turned into steam before reaching the metal it will not exert any cooling effect, except indirectly by lowering the temperature of the flame, and such lowered temperature is accompanied by a considerable loss of efficiency. On the other hand, water which reaches the walls in liquid form and is there evaporated, absorbs out of the heat given to the walls by the gas the whole of its own heat of evaporation, and there is no loss of thermodynamic efficiency, because the heat used is waste heat, which, in a jacketed engine, would go to warm the cooling water.

The author claims that it is of no use to inject the water in a fine spray, or to introduce it into the gas or air pipe, so that it is carried in suspension in the incoming charge, or, as is often done in oil engines, to spray it in along with the oil. Although some of these devices have proved useful for the prevention of pre-ignition and for the softening of the explosion, none are effective for the purpose of cooling.

The author found, however, that by injecting water in comparatively coarse jets against the internal surface of the cylinder, and the head of the piston, the metal can be kept cool without materially cooling the gases, with the result that there is no loss of efficiency. The temperature of the parts can be perfectly controlled, and simple single-walled castings can be used for the cylinders.

Experiments of Dugald Clerk, the author, and others have shown that the rate of heat-flow from the gas into the metal is far more rapid at and soon after the instant of ignition than at any other time. It seems likely from these experiments that for practical purposes the heat flow into the barrel of the cylinder during the last three-fourths of the expansion stroke might be so small compared with that in the first period that direct cooling of this portion of the cylinder could be dispensed with altogether. This anticipation has been found correct, and

it has been found necessary only to direct the spray against the walls in the combustion chamber, and the piston, the rest of the cylinder being kept cool by conduction. Cold water is injected through a hollow casting projecting into the combustion chamber and provided with a number of nozzles or holes about 1/32 in. in diameter, from which the jets are projected against the metal surfaces.

For the purpose of experiment, an 11½ x 21-in. Crossley engine, rated at 40 h.p., was fitted with a new cylinder consisting of a plain barrel without a water jacket. The injection rose is a hollow casting projecting into the combustion chamber and provided with 25 holes. The drip from the rose suffices to cool the exhaust valve. A simple plunger pump driven by a cam injects a charge of water once in a cycle, lasting from about 30 deg. before to 30 deg. after the point of the sliding surface of the barrel is covered by the piston. The quantity of water used was about 2.4 lb. per brake horse-power-hour, and the temperature of the engine ranged from 150 to 180 deg. C. The engine consumed about 15 cu. ft. of coal gas per brake horse-power-hour, both when it was water-jacketed and after being fitted with the new cylinder.

Tests at other loads showed that with a weak mixture the gas consumption is slightly increased by the water injection, but with very rich mixtures it is a trifle less. The difference, however, does not exceed 5 per cent. either way, and on the average it may be said that the economy is unaffected by the use of this method of cooling.

This engine was set to work driving a dynamo, and its speed was increased from 180 to 195 r.p.m., when it was found capable of developing 50 b.h.p. for many hours, an increase of 25 per cent. on its original maximum safe load. It has now been running for a total period of 5,000 hours on regular work, giving no trouble at all, and the combined wear on both cylinder and piston is less than 0.01 in.

To regulate the water supply in accordance with the load the pump is connected to the governor, which is of the hit-and-miss type, so that the pump only takes a stroke when the engine takes gas.

With a throttle governor a corresponding regulation is easily provided. A simple thermostat has also been devised, which automatically controls the supply of water during starting, and when the engine is running, quite satisfactorily.

In case of failure of the water supply, nothing happens except that the engine slowly heats up, and after ten minutes or so, pre-ignitions occur, bringing the engine to a standstill. No damage results from this, but to guard against any possible danger a fusible safety plug is screwed into the combustion chamber, which melts if the cylinder gets too hot, and the noise of the escaping gases warns the attendant.

The system has also been applied to an engine of 105 h.p., and to one of 1,000 h.p.; in each case the original cylinder was used, without water in the jacket. The large engine was run under load 30 hours without a stop; after a short stop for adjustments, it ran for 70 hours without a stop, driving a factory, and developing an average of 800 h.p. The whole of the injection apparatus for the 1,000-h.p. engine cost only $100, and within a few hours of putting it on the engine it was doing all the work of the cooling tower, centrifugal pumps, etc., previously used. An 18 x 24-in. two-stroke-cycle single-acting engine has been built for use with the new system, and is now undergoing trials.

COAST TO COAST.

Calgary, Alta.—The G.T.P. is erecting a temporary station, pending the conclusion of negotiations for permanent terminals.

St. John, N.B.—Two of the longest branches of the branch railways projected are now in operation, while the other three are in process of construction.

Toronto, Ont.—The date of the completion of the Dominion Government's harbor contracts has been set at four years hence.

Victoria, B.C.—The Daily Times contains an editorial calling attention to the uncertain suspension in the plans for the terminals on the reserve and magnificent bridge that was to span the harbor from Johnson Street. The government announced this construction about a year ago.

Vancouver, B.C.—Eighty miles of double track have been completed from Vancouver west to Ruby Creek, and have been inspected by the Railway Commission Engineer. Formal approval for the operation of the second track is expected shortly.

Toronto, Ont.—It will be requested before the Ontario Railway Board that the Toronto Railway Company be compelled to extend their line west along Bloor Street from Dundas Street to Quebec Avenue, instead of constructing the projected Toronto suburban line along Annette Street and Pacific Avenue.

Ottawa, Ont.—The question of pollution of navigable streams and their tributaries, upon which a special committee of the House of Commons heard last season a great deal of evidence and gave a report, will likely furnish food for a conference between the provincial and federal authorities this autumn. The report recommended the calling of an interprovincial conference, and it is understood that all provincial governments will be called upon to send delegates to a gathering of experts to be held in Ottawa in November.

Winnipeg, Man.—Mr. George Bury, vice-president of the C.P.R., has stated that the program mapped out by the company for 1913 will be completed to the last detail, and that all the grading and steel work planned to be done will be finished this year. Concerning the double tracking, he said that more of it would be in operation before the close of the year.

Edmonton, Alta.—It was stated by Sir William Mackenzie on his return trip from inspecting the western progress of the C.N.R., that construction was now 74 miles beyond the British Columbia border, and that the company hoped to have the road to the coast completed by the end of 1914. He added that 300 miles of branch lines have been laid through the prairie provinces this year, and that, taken in all, the C.N.R. has laid 840 miles of new track since the beginning of the year.

Toronto, Ont.—Hydro power has enabled the farmer of Western Ontario to chop ensilage, thresh grain, and stock his barns by electrical energy. This revolution of the system which handles the annual harvest will, according to present indications, branch out beyond Ontario boundaries. Negotiations are now under way, it is understood, between Detroit and Windsor for the sale of power to the American city for like industrial purposes. The Hon. Adam Beck has stated that, though this is the first instance where power has been sought in this way, all municipalities agree that such disposal of power could be arranged under certain restrictions. A town could sell of its surplus to the extent of 7,500 horse-

power, and anything in advance of that should be returnable from time to time as required, on a year's notice. Thus, municipalities might be aided by the payment of fixed charges until they require the full voltage for their own industries. Where a permanent disposal of power would be desired, the matter would have to come before the commission.

Calgary, Alta.—Sir William Mackenzie made the statement on September 17th that he expected to see the C.N.R. in operation in Calgary within sixty days. It is the opinion of shippers that though the line is somewhat rough, it is in good enough condition for freight traffic.

Moose Jaw, Sask.—The shortage of the supply of cement throughout western cities is not being felt in this city. Owing to the renewed building activity of late, the supply on hand in city warehouses was taxed to keep up with the demand, but no serious hold-up in business operations was caused.

Ottawa, Ont.—At the instigation of the Canadian Manufacturers' Association and the Ottawa and other Boards of Trade, the railway board has asked the railways to extend their cartage system until January 1st. So far negotiations have been without result, but it is hoped that transportation interests will be strong enough to provide a reasonable agreement until the whole matter is finally settled.

Ottawa, Ont.—This is the first fall that the two conservation dams of the Upper Ottawa have been working to their full capacity and consequently there will be a great deal of interest particularly among power owners concerning the effect these dams will have on the volume of water available at the Chaudiere. So far it would seem that these dams are very effective in holding back the water for the low water seasons. This has been a very dry season and consequently the amount of water coming down to the Chaudiere would be expected to be very much reduced. However, it has held up remarkably well. At the very low water period a few years ago there were only 7,000 cubic feet of water per second flowing at the Chaudiere, while now the flow is about 24,000 cubic feet, or over three times as much. The two dams, at Kippewa and at Temiskaming, are both in operation this year. They hold back the water in the wet seasons and let it out in the dry seasons in order to keep the level of the river more nearly uniform all year. Then they begin about November to store up water again from the fall rains and let it out during the winter. The government is now building a third dam at Lake Quinze, which is farther up and will increase the storage capacity considerably. To give an idea of the vast amount of water these dams conserve, it is equal to a body of water with an area of 4,000 square miles and a depth of one foot. Besides making the water higher in the low water periods it will to a certain extent relieve the floods of the spring by holding back the water. The work has been conducted by the Dominion government and will cost about $1,000,000.

Saskatoon, Sask.—The Canadian Pacific Railway is contemplating the building of a direct line from Calgary to this city, which will make the second direct line of communication between the two cities. The Grand Trunk Pacific has already chosen its right-of-way into the city.

Toronto, Ont.—Prof. A. T. Laing, of the University of Toronto, has returned from his travels through Italy, Switzerland, France and Great Britain. During the four months of his absence he devoted most of his time to the study of roadway conditions. Prof. Laing stated that one, after travelling abroad, and particularly in Scotland, is impressed with the fact that there is still much to be learned or put into practice in Canada in order to keep pace with other countries, or to meet even in a remote way the economic requirements essential to development. The time has come, said he, when the older and more densely populated districts much have better transportation facilities. Prof. Laing remarked that, as Toronto was surrounded by the best of agricultural land, he could see no reason why she should not be served by the district within a radius of thirty or forty miles. But this he believed to be impossible with the present conditions of the roads. By the use of the motor truck produce can be carried fifty miles in the Old Land.

Kerrisdale, Point Grey.—A lighting experiment is being tried in Point Grey, which, it is said, has already been favored by delegations of ratepayers from Wards Two and Three who have examined it. Point Grey is the first municipality in the district to endeavor to determine what can be accomplished by a municipal lighting and heating plant, and other municipalities are stated to be keenly watching the progress of events. The light, which is very brilliant, and yet soft to the eyes, is obtained from gas manufactured from petrol, and is declared to be produced at a very low rate, the trial working out at a cost of about 60 cents per thousand cubic feet of gas. The plant works on an automatic principle, it being said to only require attendance about once in six months. The illuminant is now on trial, and if successful a proposal may be made for the municipality to undertake the lighting of the district. The gas can be used for a variety of purposes, street and house lighting, house heating and cooking purposes. If this principle is adopted, small plants will be erected in various parts of the municipality, this being a better method than having one large central plant, as it will not be necessary then to have large gas mains throughout the area, the small plants being able to supply each section through small pipes. No scheme, however, has yet been outlined, the matter still being in a tentative stage.

Montreal, Que.—The Harbor Commissioners, at a conference held recently with the Hon. J. D. Hazen, Minister of Marine and Fisheries, obtained an additional grant of $18,000 for the purpose of completing the new addition to the grain elevator, the original grant of $50,000 being found insufficient. The Commissioners hope that the only works contemplated in the harbor for the immediate future will be finished this year. On their return they expressed extreme gratitude for the liberality the Minister had shown in granting their requests. The question of a free port, which has been agitated here for some time, was also briefly discussed. In the opinion of Commissioner Robertson, Montreal was already a free port, and the Board of Trade and other commercial bodies were, therefore, asking for something they already had. Mr. Robertson stated that he was unaware where any port existed at which there were no tolls to correspond to all the harbor charges in Montreal. The report of the Royal Commission on Transportation in its last sitting, urged that Montreal be established as a free port; but this Mr. Robertson held had already been done, though without any special sanction from Parliament.

Montreal, Que.—An additional $20,984 for sidewalks is the request of the Board of Control from the City Council as a result of Superintendent Barlow's report, submitted at a recent meeting. It is found that more sidewalks than it was expected can be laid this year before cold weather sets in, and the supplementary amount of money is requested that as much work as possible can be done, especially on streets which have been paved, but on which sidewalks are not yet laid.

Ottawa, Ont.—About 1,000 tons of peat from the plant at Alfred, Ont., will be sold in Ottawa this winter. The price of this commodity to Ottawa people will probably be $5 per ton. The Government three years ago, as an experiment, installed a plant there that had proved most successful in Europe, and turned out thirty tons a day. Later, the Govern-

ment sold their portion of the bog to private interests, who have installed improved machinery. Two years ago peat from this bog was sold here, and found a ready market. By analysis one ton of hard coal goes as far as one ton and three-quarters of peat, but by actual practice this is not the case; for much is lost in the coal by combustion and in the escaping of half-burned clinkers, whereas in peat the combustion is almost complete, and the substance is burned away to a fine ash. Canada has 37,000 square miles of known peat bogs, constituting a potential national asset of enormous value. Four bogs, within five miles of Ottawa, examined by Government experts, are estimated to contain over 25,000,000 tons of fuel.

Toronto, Ont.—The Toronto Hydro-Electric system made a profit of 13.19 per cent., or $71,000 during the first six months, ending July 1.

Fort William, Ont.—The Board of Railway Commissioners for Canada, at a sitting in Ottawa, September 16th, granted permission for the Grand Trunk Pacific Railway Company to construct a double track branch line from its main line at Empire Avenue, Fort William, northward on what was formerly known as James Street, thence easterly along the city limits to Thunder Bay. The new spur track will be over three miles in length and will open up and serve a large industrial area as well as giving the Grand Trunk Pacific Railway access to the new Government elevator.

Winnipeg, Man.—Track laying on the main line of the G.T.P. Railway is progressing towards Prince George at a rapid rate. Steel is at mile 1,200 from Winnipeg. While the steel bridge across the Fraser River was being completed, a short check was experienced at mile 1,197, where the railway for the second time crosses the Fraser River. This obstacle has now been successfully passed, and the track laying machines are steadily pushing their way forward. The Fraser River is crossed for the third time about 40 miles west of the second crossing, but the bridge here will not be allowed to delay track laying, and a temporary trestle will be erected to get the steel across the river. The steel bridge will be put in place shortly after, and towards the end of November the track should reach Prince George. One hundred and four miles of branch line in the province of Saskatchewan have just been opened for traffic by the G.T.P Railway, with the inauguration of a mixed train service on a part of the Biggar-Calgary branch. This line has been completed to Loverna, on the boundary line between Saskatchewan and Alberta, 104 miles from Biggar. Track laying on the Regina-Moose Jaw and north-westerly branch of the G.T.P. Railway has just been completed to mile 91, a short distance beyond Mawer, Sask., and within a couple of miles of the Saskatchewan River. Permission has just been granted by the Board of Railway Commissioners for operation of this line, and it is probable that a considerable amount of wheat will be shipped over it this year.

Montreal, Que.—Mr. H. S. Holt, president of the Royal Bank, and of the Montreal Light, Heat and Power Company, made some interesting observations on the progress of the work of the C.P.R., throughout the past year. He states that the company is spending in the west on extensions, terminals, and double-tracking, as much as, if not more than, it spent on the original system; that 1,100 miles of new trackage are under way at present and thousands of men at work on their construction; that over $30,000,000 is being expended this year in the west, and in no part of the system is finality disclosed; and concerning the Windsor and Place Viger stations, that before the company has finished their construction with the offices and the slow and tedious system of trackage involved, there will have been an expenditure of about $8,000,000.

PERSONAL.

A. P. LOW, Deputy Minister of Mines, Ottawa, will retire shortly.

H. C. QUAIL, B.A.Sc., has received an appointment to the staff of the Midland Construction Co., at Healey Falls, Ont., and assumes his duties this week.

CHAS. B. GORDON, of Montreal, was elected president of the Canadian Manufacturers' Association at its recent convention in Halifax.

FRANK S. STREETER, one of the United States members of the International Joint Commission has resigned and OBADIAH GARDNER, ex-Senator, Maine, has been appointed in his stead.

CHARLES T. MILLER is a name which we inadvertently omitted from the list of directors of the Maritime Bridge Co., published in our issue of September 11th. Mr. Miller is secretary of the Canadian Bridge Co., Limited, Walkerville, Ont.

W. A. EVANS, recently Public Health Commissioner of Chicago, has been touring the cities of the Canadian West, and has delivered a number of instructive addresses on the subject of public health. Winnipeg, Regina, Moose Jaw, Medicine Hat and Saskatoon were among the places visited by Dr. Evans on his trip.

H. F. MEURLING, C.E., of the Columbia River Hydrographic Survey, is in charge of work near Burton, B.C. The river is undergoing measurement and soundings to find out whether a dam and locks can be built below the narrows at Caribou Point, to raise the water sufficiently for navigability throughout the entire year.

OBITUARY.

DONALD J. McLACHLAN, a well-known contractor of Calgary, died on September 22nd.

AUSTIN BARRETT, in charge of a survey party in British Columbia, was accidentally shot and killed last week. Mr. Barrett was a native of Puslinch, Ont.

E. GRAHAME-JONES, a young engineer connected with a construction party of the Canadian Northern Pacific Railway, was drowned in the Fraser River, near Lytton, B.C., by the upsetting of a small boat. Mr. Grahame-Jones' home was at Stanstead, Surrey, Eng.

COMING MEETINGS.

AMERICAN SOCIETY OF MUNICIPAL IMPROVEMENTS.—Twentieth annual meeting to be held in Wilmington, Del., October 7th to 10th. Secretary, A. Prescott Folwell, 15 Union Square, New York.

UNITED STATES GOOD ROADS ASSOCIATION.—Convention will be held at St. Louis, Mo., November 10th to 15th. Secretary, J. A. Rountree, L021 Brown-Marx Building, Birmingham, Ala.

AMERICAN ROAD BUILDERS' ASSOCIATION.—Tenth Annual Convention to be held in First Regiment Armory Building, Philadelphia, Pa., December 9th to 12th. Secretary, E. L. Powers, 150 Nassau Street, New York, N.Y.

AMERICAN CONCRETE INSTITUTE.—Tenth Annual Convention to be held in Chicago, February 16th to 20th, 1914. Secretary, E. E. Krauss, Harrison Building, Philadelphia, Pa.

ORDERS OF THE RAILWAY COMMISSIONERS
OF CANADA

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for small fee.

20324—September 11—Authorizing C.N.O. Ry. to construct spur for Point Anne Quarries, Limited, from main line of Toronto-Ottawa line, at about mileage 126.08, through Lots 21 and 20, Point Anne Concession, Tp. Thurlow, to join spur to be constructed by Point Anne Quarries, Limited.

20325—September 11—Approving revised location and station grounds between mileage 57 and 58, Melville-Regina Branch of G.T.P. Branch Lines Company, in Sec. 12-20-15, W. 2 M., Dist., Assiniboia, Sask.

20326—September 12—Authorizing Lake Erie and Northern Ry. to construct two (2) highways in Tp. Townsend, Ont.—namely, Con. Road from Station 1118-88 to Station 1119-52.1 and Con. Road from Station 1163-95.5 to Station 1164-65.7.

20327—September 15—Extending, until September 30th, 1913, time within which London St. Ry. Co., complete half-interlocking plant at crossing of Adelaide St.; and authorizing London St. Ry. Co. and C.P.R. to operate their cars and trains over said crossing; same to be flagged across by means of a day and a night watchman, employed by C.P.R. at expense of London St. Ry. Co.

20328—September 12—Relieving G.T.R. from providing further protection at first crossing east of Ste. Madeline Station, Co. of St. Hyacinthe, Que.

20329—September 13—Requiring that Michigan Central R.R., T.H. and B. Ry. and C.P.R. Cos., jointly reduce their rate on coal, in carloads, from Suspension Bridge, New York, Black Rock, New York and Buffalo, New York to Islington, Ont., and Lambton, Ont., from 75 cents to 70 cents per ton of 2,000 lbs., said reduced rate to become effective not later than the 27th October, 1913, and rescinding Order No. 20047, dated August 8th, 1913, made herein.

20330—September 5—Authorizing Can. Nor. Alta., Ry. to construct spur from a point on its authorized line, in N.E. ¼ Sec. 30-54-1, W. 5 M., thence across Sec. 30 and Secs. 29 and 32, said Tp. and Rge., to Wellman Gravel and Supply Company, Limited; spur to be completed within three months from date of this Order.

20331—September 16—Approving location C.L.O. & W. Ry. (C.P.R.) station building, known as Brighton, at mileage 91.1: Provided whenever traffic on highway is blocked for more than 5 minutes at any one time by reason of location hereby approved, Board be at liberty to relocate said station; also approving change or alteration in location approved by Orders Nos. 16325 and 16912, so as to include extra land required for station grounds.

20332—September 16—Authorizing G.T.P. Branch Lines Co. to carry traffic over portion of Moose Jaw Northwest Branch from Moose Jaw, mileage 40.1, Regina-Moose Jaw Branch, to Mawer, mileage 44.9, Moose Jaw Northwest Branch, a distance of 47.3 miles. Trains limited to a speed not exceeding 15 miles an hour.

20333—September 17—Approving location Edmonton, Dunvegan & B.C. Ry., from east boundary of Sec.25-72-5, W. 5 M., mileage 156.11, to west boundary of Sec. 30-74-17, W. 5 M., mileage 238.80, Alberta.

20334—September 16—Directing C.N.R. to grade approaches to crossing of road allowance between Secs. 13 and 14-54-5, W. 5 M., Alta.; that south approach to crossing of public road between Secs. 17 and 18-54-4, W. 5 M., be raised 2 ft. and made at least 20 ft. wide, and cattleguards properly adjusted: work be completed within 30 days from date of this Order.

20335—September 17—Authorizing Dominion Atlantic Ry. to use and operate drawbridge at south end of its bridge over Shubenacadie River at South Maitland, Nova Scotia.

20336—September 15—Authorizing Can. Nor. Western Ry. to construct its Red Deer Calgary Branch across G.T.P. Ry. Co.'s Tofield Branch, in N.E. ¼ Sec. 4-25-28, W. 4 M., Alta., subject to and upon certain terms and conditions.

20337—September 16—Approving location C.N.R., Alsask Branch, through Twps. 26-28, Rgs. 26-29, W. 3 M., Sask., mileage 125.45 to mileage 148.34.

20338—September 15—Authorizing C.N.Q.R. to construct across 9 highways, Twps. Lussier, Rawdon, Chertsey and Chilton, Co. Montcalm, P.Q.

20339—September 16—Relieving G.T.P. Ry. from erecting and maintaining fences on its line of railway east of Prince Rupert, to mileage 164. That operation of this Order and all relief given hereunder, in so far as any one or all of said portions of right-of-way are concerned, shall cease when and as soon as any land on either side, or in vicinity of any such portion or portions, becomes settled or improved.

20340—September 15—Approving C.N.R. Co.'s third-class station at Webster, Saskatchewan.

20341—September 15—Approving G.T.P. Branch Lines station site and station at Dorenlee, Sec. 11-43-21, W. 4 M., on its Tofield-Calgary Branch, Alta.

20342—September 15—Removing speed limitation of 15 miles an hour over C.P.R. Co.'s Bassano to Irricana Branch, between Bassano and Standard.

20343—September 17—Approving location C.P.R. Stations on Weyburn Westerly Branch, namely, Melaval, W. ½ Sec. 35-8-4, W. 3 M. Readlyn, S.E. ¼ Sec. 30-7-27, W. 2 M., Woodrow, N.W. ¼ of Sec. 35-8-6, W. 3 M., and Lafleche, E. ¼ Sec. 2-9-5, W. 3 M., all in Province of Saskatchewan.

20344—September 16—Authorizing C.P.R. to construct road diversion in Sec. 25-14-19, W. 4 M., Alta.; and to construct, by means of a grade crossing, its Suffield-Blackie Branch across said road diversion.

20345—September 15—Authorizing C.P.R., subject to and in accordance with terms and conditions contained in agreement, entered into between Municipality of Elcapo, Sask., Town of Broadview, and C.P.R. Co., dated July 2nd, 1913, after diversion of Front St. is made, to close portion of road allowance, within limits of right-of-way of main line, Sask. Div., between Sec. 26 and 27-16-5, W. 2 M., at Broadview, Sask.; and authorizing opening of streets in said City.

20346—September 17—Extending, until Nov. 15th, 1913, time within which C.P.R. complete spur for Canada Wire & Cable Co., Ltd., authorized to be constructed under Order No. 19471.

20347—September 16—Approving location C.N.R., Grosse Isle Branch, through Twp. 25, Rgs. 1 and 2, W.P.M., Manitoba, mileage 74.47 to mileage 80.88.

20348—September 17—Directing that C.P.R., within 60 days from date of this Order, install improved type of automatic electric bell at crossing of Port Burwell Road, at mileage 32.7, Port Burwell Branch; 20% of cost of installing bell be paid out of "The Railway Grade-Crossing Fund," and remainder by Rly. Co.

20349—September 11—Authorizing C.L.O. & W. Ry. (C.P.R.) to cross (a) Prospect St., at grade; crossing be protected by gates installed and maintained by Rly. Co. (b) Albert St., by diverting said St. and carrying it over Rly.; and authorizing Rly. Co. to take whatever additional land may be required for purposes of said overhead crossing. (c) Simcoe St., by means of bridge carrying street over railway, and (d) Divert Centre St., by extending Hall St., easterly to a connection with Simcoe St., and to close existing crossing on Centre St. 2. Approving location of Rly. Co.'s station.

20350—September 17—Approving G.T.P. Co.'s station and station site at mileage 1179.2, Cariboo District, B.C.

20351—September 18—Amending Order No. 20148, dated August 20th, 1913, by adding words "and maintain" after word "construct," in second line of operative part of said Order.

20352—September 17—Authorizing C.P.R. to open for traffic portion of second main line of Cascade Sub. Div., between mileage 86.8 and mileage 47.8, a distance of 39.0 miles

20353—September 18—Amending Order No. 19832, dated July 18th, 1913, to provide that expense of constructing and maintaining crossings authorized under said Order, be borne and paid by the Railway Company.

20354—September 17—Authorizing G.T.R. to construct siding into premises of Dominion Textile Co., Ltd., Montreal, Que.

20355—September 17—Authorizing G.T.R. to construct siding into the premises of Grasselli Chemical Co., Ltd., Montreal, Que., subject to and upon certain conditions.

20356—September 17—Authorizing C.P.R. to construct spur into premises of Ogilvie Flour Mills Co., Ltd., on Lot 11, Block E, at Calgary, Alberta.

20357—September 17—Authorizing C.P.R. (1) to construct diversion of road allowance in Sec. 14-16-20, W. 4 M., Alta.; (2) to construct, by means of a grade crossing, Suffield-Blackie Branch across said diversion, at mileage 83.97.

20358—September 17—Authorizing Dominion Atlantic Ry. to construct bridge over Cambridge Brook, situated 77.9 miles from Halifax and about 300 ft. east of Cambridge Station, Co. Kings, N.S.

20359—September 17—Authorizing Can. Nor. Alta. Ry., to construct spur for Jasper Park Collieries, Ltd., through Sec. 7-49-27, W. 5 M., and Sec. 12-49-28, W. 5 M., mileage 0 to mileage 0.76.

20360—September 19—Relieving G.T.R. from providing further protection at crossing of Tecumseth Road, one mile east of Stoney Point Station, Ontario.

20361—September 19—Approving amended location of G.T.P. Ry. station at Smithers, mileage 226.5, Prince Rupert East, Lot 5289, Rge. 5, Coast district, B.C.; and rescinding approval of station at mileage 227, Rge. 5, Coast District, under Order No. 16278, dated April 9th, 1912.

General Order, No. 111—September 18—Amending second paragraph of mandatory portion of General Order No. 111, dated August 20th, 1913, by inserting following words after word "That," in first line of said paragraph—namely, "the present tariff rates be reduced by five cents per can by making them exclusive of delivery, and that." This amendment be operative from date of said General Order No. 111.

20362—September 19—Authorizing C.P.R. to construct five (5) bridges—namely:—1. At mileage 78.4, Moose Jaw, to be extended for double track, Sask. Div., Indian Head, Regina. 2. At mileage 3.2, Moose Jaw Subdivision, for double track. 3. At mileage 87.0, Rush Lake, Swift Current Section, Western Div., for double tracking. 4. At mileage 92.1 over Antelope Creek, Swift Current Section, Western Div., to provide for double tracking, and 5. Bridge No. 101.2, for double tracking, Swift Current Subdivision, Western Div.

20363—September 19—Amending Order No. 18931, dated March 27th, 1913, by striking out words, "and freight shed facilities," in fourth line and words "and freight," in sixth line of operative part of said Order.

20364—September 19—Directing that C.N.R. provide and install a standard one-pen, two-car capacity, stock yard, with platform and chute, at Sturgis, Sask.; work to be completed not later than October 10th, 1913.

20365—September 20—Authorizing C.P.R. to construct spur into premises of Canadian Concrete Products Co., Limited, Chatham, Ontario.

20366—September 20—Authorizing C.P.R. to construct two (2) bridges—namely, bridge at mileage 52.5, between Secs. 22 and 21-13-18, W. 2 M., Moose Jaw, Subdivision, Sask.; and proposed extension of bridge at Rush Lake, mileage 73.4, Swift Current Section, Western Div., both in Province of Saskatchewan.

20367—September 20—Authorizing G.T.P. Ry. to carry traffic over that portion of main line east of Prince Rupert, B.C., between Morricetown, mileage 205 and mileage 301; operation of trains over said line to be limited to a speed not exceeding 25 miles an hour between mileages 205 and 245; 15 miles an hour between mileages 245 and 301; and six miles an hour over uncompleted bridges and temporary crossing of Bulkely River at mileage 263.

20368—September 20—Authorizing G.T.R. to construct two (2) bridges in Province of Ontario—namely, bridge No. 59, mileage 147.53, from Black Rock, over Bevfield Creek, 20th Dist., London Div. and Bridge No. 202, mileage 150.75, near Huntsville, over Big East River, 12th Dist., Barrie Div.

20369—September 22—Extending for a period of 30 days from date of this order, time within which G.T.R. construct and complete certain spurs into premises of Pilkington Brothers, Limited, Tp. Thorold, Co. Welland, authorized to be constructed by Order No. 19601, dated June 17th, 1913.

20370—September 20—Approving location C.P.R. stations, in Prov. Sask.—namely, 1. At Lemsford, S.W. ¼ of Sec. 10-22-23, W. 3 M., at mileage 69.00, Swift Current Northwesterly Branch. 2. At Abbey, S.E. ¼ Sec. 31-20-20, W. 3 M., at mileage 50.66, Swift Current Northwesterly Branch and 3. at Prelate, in S.E. ¼ of Sec. 9-22-25, W. 3 M., at mileage 81.70, Swift Current Northwesterly Branch.

20371—September 2—Directing that G.T.R. employ watchman at crossing of Edinburgh St., Guelph, Ont., between the hours of 7 a.m. and 7 p.m.; railway company to pay expense of said watchman.

20372—September 22—Approving plan and specifications of drain known as John Beck Drain, to be constructed under G.T.R., at mileage 20.14, Tp. South Norwich, Co. Oxford, Ontario.

20373—September 20—Authorizing C.P.R. to open for traffic portion of double track of its Broadview Subdivision, from Kemnay, mileage 8.2, to Griswold, mileage 24.8, Manitoba.

20374—September 22—Authorizing C.P.R. to construct two (2) bridges—namely, 1. Bridge No. 9.3, near Red Deer, Edmonton Subdivision, Alta. Div., Alta.; and 2. Bridge No. 113.1, near West Shefford Station, Sherbrooke Subdivision, Eastern Div., Quebec; and rescinding Order No. 20092, authorizing the construction of said bridge No. 113.1.

20375—September 20—Authorizing C.N.Q.R. to construct across public road in Lot 15a, Tp. Rawdon, Co. Montcalm, Que.

20376—September 20—Authorizing C.N.R. to construct a bridge to carry its railway across C.P.R. main line and Moose Jaw Creek (third crossing), at mileage 86.1, Sask.

20377—September 22—Authorizing C.P.R. to construct spur for Whitlock and Riddell, city of Moose Jaw, Sask.

20378—September 22—Authorizing C.P.R. to construct spur from station grounds at Camrose in northerly direction across North Railway Ave., across portions of Lots 6 and 7, Block 48, and lane in rear of said lots, thence along lane through said Block 48, across Edgell Ave., and along portion of lane in Block 1; to construct a second track across North Railway Ave., to premises of Vernon Fruit Co., Limited, in Lot 8, Block 48, and third track across portion of lane in Block 1, into premises of Provincial Telephone Co., on Lot 8 to 16, inclusive, Block 1, town of Camrose, Alta.

20379—September 22—Exempting C.P.R. from complying with requirements of Section 364 as to publication of notice of application; and recommending to the Governor in Council for sanction Agreement, dated August 15th, 1913, entered into between his Majesty the King, represented and acting by the Honorable the Minister of Railways and Canals and C.P.R.

20380—September 22—Authorizing C.P.R. to construct extension to spur already constructed for Western Coal Co., from a point on existing spur into premises of Western Coal Co., Limited, situate on Lot 6, Block 21, D.G.S., 35, parish St. John, Winnipeg, Man.

20381—September 22—Authorizing Montreal and Southern Counties Ry. Co., to operate trains over crossing of G.T.R., on Lot 264, parish St. Antoine de Longueuil, at a point 7.45 miles from Montreal, without their being brought to a stop.

20382—September 23—Authorizing C.N.O.R. to construct across St. Denis St. (now Albert St.), Montreal, by means of a structure carrying railway over highway.

20383—September 23—Authorizing C.P.R. to divert road along southwesterly side of right of way, from road allowance along northerly side of N.E. ¼ Sec. 35-39-23, W. 4 M., Alta., to Leon St., village of Alix, Alta.

20384—September 19—Amending Order No. 20230, dated August 30th, 1913, by adding following clause:—"It is further ordered that this order by without prejudice to the rights of Napanee River Improvement Co., to recover from Applicant company, such damages as it may legally be entitled to by reason of the diversion of the river or the construction of the said bridge; and that if the parties are unable to agree, the question of whether any such damages have arisen by reason of such works, and the amount thereof, if any, shall be decided by arbitration under the provision of the Arbitration Act (Ontario)."

Barrett Specification Roofs

Last Longest—Cost Least

THE proper unit in comparing the values of roofings is the cost-per-foot-per-year-of-service.

To have a low unit cost a roofing must be—

1st. Inexpensive to build,
2d. Inexpensive to maintain, and
3d. Of great durability.

Barrett Specification Roofs are—

1st. The *least* expensive of all permanent roofs to build,
2d. They cost *nothing* to maintain, and
3d. They usually last, without repairs or leaks, *20 years* or over.

The net result of these three factors is a unit cost of about ¼c. per foot per year of service. This is a lower unit cost than ever attained by any other class of roofing.

Accordingly, Barrett Specification Roofs are in almost universal use on buildings such as illustrated herewith, where unit costs are intelligently studied.

Herald Building
Montreal

Architects—Brown & Vallence, Montreal
G. C. Nicholson & Co., Montreal
Roofers—Metal Shingle & Siding Co., Montreal

Copy of the Barrett Specification with tracing ready for incorporation in your building plans sent free on request. Address nearest office.

Special Note

We advise incorporating in plans the full wording of the Barrett Specification, in order to avoid any misunderstanding.

If any abbreviated form is desired however, the following is suggested.

ROOFING—Shall be a Barrett Specification Roof laid as directed in printed Specification, revised August 15, 1911, using the materials specified and subject to the inspection requirement.

RAILWAYS—STEAM AND ELECTRIC.

Calgary, Alta.—Athabasca citizens are agitating a change in the route of the Alberta and Great Waterways Railway. As planned, the line will miss Athabasca Landing, would run about 30 miles east of the town and strike the river at a point where the river, after running easterly from Athabasca, turns northward, and thence proceed directly to Fort McMurray. The importance of Athabasca Landing, as a northern trade centre, would thus be minimized, and the inhabitants contend that the logical route is to continue the line from Athabasca Landing to Fort McMurray.

Edmonton, Alta.—The vexed question of the Alberta and Great Waterways Railway case has been settled in a manner satisfactory to the government and all interested. Mr. J. D. McArthur and his associates, owners of the Edmonton, Dunvegan and British Columbia Railway now being completed to Peace River, builders of a large section of G.T.P. Railway and at present of the Hudson's Bay Railway, have taken over the charter, and will complete the road and assume all existing liabilities.

Edmonton, Alta.—Though several portions of the G.T.P. road, under construction, have still to be completed, there is every prospect that steel will be laid as far as Fort George by January 1st. At mile 226, there is approximately 400,000 feet of earth and rock to be removed and a large fill-in made: but with a seventy-ton steam shovel at work, this should be completed before the track-laying crews arrive. These are expected in about three months.

Fort William, Ont.—The C.P.R. has completed the subway, and the company which held the contract has moved its outfit to Saskatoon. The road, however, to be used by the public is still unfinished. Whether this is the work of the company or of the city is apparently undecided.

Hamilton, Ont.—The application of Chadwick Brothers for permission to construct a spur line from the G.T.R., will not be granted owing to the objection of residents.

+—Ottawa, Ont.—The contract has been awarded MESSRS. ELBERT SOPER and A. L. McDOUGALL, of Ottawa, for constructing four miles of new track for the Intercolonial Railway, from St. Romuald to Chandière Curve, in Quebec.

Ottawa, Ont.—Reports of engineers indicate good progress on the Hudson Bay railroad. Before the coming year a straight stretch of 150 miles grading will have been completed. Thus, with the exception of a few cuts, the line will be graded from Pas to Thicket Portage, a distance of about 200 miles. About sixty miles of rails have been laid, and before frost sets in to stop the work, it is expected that the rail mileage will pass the seventy mile mark.

Victoria, B.C.—As a result of the investigations carried on by Mr. F. H. Burrall, a New York mining engineer, in accordance with instructions from the president of the White Pass and Yukon Railway, Mr. O. Dickeson, with a view to a possible extension of the line, the company have been so favorably impressed as to contemplate commencing work on an extension of their line next year.

Winnipeg, Man.—An order has been issued from the Public Utility Commissioners' office for the construction, in accordance with the order of the Railway Board for Canada, and in the manner designed therein, of the necessary appurtenances and equipment for crossing the C.P.R. tracks on Selkirk Avenue by the Winnipeg Street Railway, and for the construction of an extension of the company's tracks along Selkirk Avenue to McPhillips Street. The whole construction is to be completed by November 15, 1913.

GARBAGE, SEWAGE AND WATER.

Calgary, Alta.—Commissioner Graves states that the new pumping plant will be in operation in every part of the city early in November, and in most of the city with the exception of East Calgary within a shorter space of time. The line of pipe cannot be run across the river until the water in the Elbow is at its lowest.

Hamilton, Ont.—The proposition of doing away with the filtering basins at the Beach will be opposed by Controller Cooper, representative for the Board of Control on the committee in charge of the Beach waterworks plant, until it has been shown that the good water enjoyed by Hamilton for years and the lack of typhoid epidemics are not the outcome of the filtration system.

London, Ont.—The Board of Works have provided a secondary by-law to be placed before the people in addition to the by-law for storm-sewers, to the effect that the East end be furnished with a new sanitary sewage outlet system at an estimated cost of $50,000.

Montreal, Que.—Tenders will be received up till October 3rd, 1913, for the construction of sewers in eleven of the city's streets. Plans and specifications may be obtained from Board of Commissioners. L. N. Senecal, Secretary.

Regina, Sask.—The six different sewer contracts let this year in as many sections of the city, under the general supervision of the city engineer, are being rapidly and satisfac-

MANNESMANN STEEL PIPE

FOUR STRONG POINTS:

1.—Our tubes can be bent cold on the spot without trouble.

2.—Our tubes can be supplied in lengths up to forty feet, thus effecting a large saving in joints, jointing material and labor.

3.—Leakage is reduced to a minimum, as the joints are far tighter and seventy per cent fewer.

4.—Saving in freight, etc., is considerable, as a steel tube weighs one-third to one-half as much as a cast iron pipe of the same length. And there are other convincing reasons and illustrations in our booklets.

BOOKLETS ON REQUEST

Mannesmann Tube Co., Limited 51 Victoria Square **MONTREAL**

torily carried towards completion. The policy of the letting of contracts this year has been fully justified by the progress made.

▲—**Toronto, Ont.**—Tenders will be received up till October 4th, 1913, for the construction of a sewer on Wychwood Avenue, in the Township of York. Plans and specifications may be obtained from office of Frank Barber, C.E., 57 Adelaide Street East, Toronto. Frank Barber, Township Engineer.

Victoria, B.C.—The municipal council of Oak Bay is directing its attention to the necessity for the extension of its sewage and water systems to the entire area within the municipal bounds, and to this end a by-law is soon to be drafted to secure the authority of the ratepayers.

Victoria, B.C.—Tenders will be received up till October 6th, 1913, for 10,000 feet of 3-inch fibre conduit. Plans and specifications may be obtained from W. Galt, Purchasing Agent, Victoria, B.C.

Washington, D.C.—The committee of the International Joint Commission, which will present a report to the entire commission in Ottawa next month, are emphasizing the necessity for immediate measures to protect the health of the Great Lake cities against sewage pollution of water. The report holds that the principal sewage pollution comes from the sewage disposal at Buffalo and recommends that the method of disposal be changed there in the near future. Conditions of sewage pollution along the Detroit River is a more difficult problem, and is to be further investigated by sanitary experts. In a supplementary report, Mr. Frank A. Streeter, of the commission, holds the opinion that only federal control of sewage pollution can furnish effective remedies where the pollution of an interstate stream by one state menaces the health of citizens of another, and that "Congressional action may wisely be taken to provide federal control in the interests of public health."

+—**Winnipeg, Man.**—The contract has been awarded by the Board of Control to the DOMINION CONSTRUCTION CO., for the construction of a sewer on Martin Avenue, from Kelvin Street to Brazier Street.

LIGHT, HEAT AND POWER.

Belleville, Ont.—Tenders will be received up till October 6th, 1913, for heating, plumbing and electric wiring of the boys' dormitory at the Institution for the Deaf and Dumb, Belleville, and the Institution for the Blind, Brantford. Plans and specifications may be obtained from the institutions named. Signed, H. F. McNaughton, Secretary, Public Works Department.

+—**Calgary, Alta.**—The city of Calgary has recently placed an order with the IMPERIAL WIRE AND CABLE COMPANY, LIMITED, Montreal, for lead covered paper insulated underground cable. Approximately 40,000 feet will be installed by the city under the supervision of Mr. R. A. Brown, City Electrical Engineer.

London, Ont.—On October 16th, 1913, the same day upon which the citizens of London will vote upon expenditure of $400,000, for storm sewers, a by-law asking the ratepayers to vote $700,000 for the electrification of the London and Port Stanley railroad will also be submitted.

Medicine Hat, Alta.—The gas committee's report in which the council was requested to authorize an additional 50 lights in the city's streets, was unanimously adopted.

Nelson, B.C.—The City Council has been petitioned by residents of Vernon Street, between Josephine and Hall Streets, that the Tungsten standard system be extended to that district. Extension to Rosemont and Vancouver Street districts has been granted.

Nelson, B.C.—Terms have been agreed upon between Mr. Fred Burnett, of the Toronto Economical Gas Apparatus Construction Company and the city council for the Nelson gas plant at an estimate of $50,000, payable in 50-year bonds, bearing interest at 6 per cent. per annum. A by-law will be submitted to the people when the necessary legal steps have been taken.

+ **Ottawa, Ont.**—The city of Ottawa has placed an order with the IMPERIAL WIRE AND CABLE COMPANY, LIMITED, Montreal, for the supply and installation of 47,000 feet 3 conductor No. 2/0 B. & S. paper insulated lead covered cable, and 1,100 feet 3 conductor No. 2/0 B. & S. steel taped cable, both insulated for 3,300 volts.

Regina, Sask.—A "cheap power" deal, which bids fair to be satisfactory to all concerned, is being negotiated between the city council and Mr. A. S. Porter, acting for the Estevan Gas Power and Development Company.

+—**Toronto, Ont.**—A contract has been awarded the IMPERIAL WIRE AND CABLE COMPANY, LIMITED, Montreal, by the Toronto Hydro-Electric system for approximately 22,000 feet of 2 and 3 conductor paper insulated lead covered underground cable, conductors ranging from No. 6 B. & S. to 500,000 C.M.

+—**Winnipeg, Man.**—The IMPERIAL WIRE AND CABLE COMPANY, Montreal, received an order recently from the city of Winnipeg for 12,000 feet of paper insulated lead covered underground cable.

BRIDGES, ROADS AND PAVEMENTS.

Calgary, Alta.—It is expected that an understanding with the International Milling Company making it possible to construct the long-contemplated subway on Fourth Street West, will soon be reached. The company will be requested to fix the amount of damage it considers it will suffer if the city goes ahead with the building of an ordinary subway. The company will be left to negotiate with the C.P.R. for a new site to build its own elevator. It is thought that this can be arranged since the milling company has shown itself willing to make the change, and the C.P.R. has indicated that it is prepared to deal for a site.

Canora, Sask.—The next important improvement to be urged before the attention of local property owners, is the matter of good roads for Canora and four municipalities bordering on the town.

Chateauguay, Que.—Since the incorporation of the town of Chateauguay, its rapid progress has made urgent the construction of a new bridge for passengers and vehicles over the Chateauguay River near the N.Y. Central Railway's bridge at Chateauguay Basin. An engineer from the Quebec government was sent recently to survey the proposed location. In addition, the town council will make many improvements upon roads and walks in the municipality during the coming year.

Fort William, Ont.—A public highway, which will form a direct route between Fort William and Duluth, will be completed, according to present indications, in 1914. Mr. F. W. Fraser, vice-president of the Fort William board of trade, states that he has been informed that most of the road on the Ontario side has been completed, but that the gravelling cannot be completed until next spring. Mr. R. J. Burdett, the secretary of the board, reports through the statement of the editor of the Duluth Herald, that much of the road has been finished between Duluth and the boundary, that it is proposed to boulevard the road for a considerable distance from Two Harbors and that, it is reported, the Commercial Club of Detroit are making good progress in its endeavor to have the State and the United States Governments appropriate $50,000 each for the improvement of this road as well as for the construction of others.

Fort William, Ont.—The board of trade have taken into consideration the improvement of the subway leading to the public dock. The tunnel is in need of new walls, a roof, lights, and a new pavement.

Halifax, N.S.—Tenders will be received up till October 11th, 1913, for the construction of the substructure of and embankment to Lennox Passage bridge in the County of Richmond, N.S. Plans and specifications may be obtained from the Commissioner of Public Works and Mines, Hon. E. H. Armstrong, Halifax, N.S.

Kingston, Ont.—Satisfactory progress is reported on the pavement under construction in this city by the Ontario Asphalt Block Co., of Windsor

London, Ont.—The city engineer and two of the city's aldermen were sent to the American Good Roads' Congress in Detroit, to report upon the advocacy of storm sewers. Should they be favored by the electors a programme for paving streets of the city will be undertaken.

+—**Montreal, Que.**—The contract has been awarded MR. JOHN ROSS, of the firm ROSS AND McCOMB, for build-

ing the concrete substructure of the bridge being constructed by the Montreal and Southern Counties Railway Co., over the Yamaska River, at St. Cesaire.

Montreal, Que.—The Board of Control have presented to the city aldermen a report asking for the construction of sidewalks on a number of the city's streets, amounting in cost to $20,984.74.

New Glasgow, N.S.—Owing to the delay in receiving from the United States certain parts of the steel span which are not rolled in Canada, the contractors, W. P. McNeil Co., Limited, New Glasgow, have been unable to erect the bridge on schedule time. But the company promises that, unless still further delay occurs in the assembling of materials, the bridge will be built during the month of October.

+—New Rochelle, N.Y.—The contract has been awarded to WILKES-CASEY ENGINEERING AND CONSTRUCTION COMPANY, of New Rochelle, N.Y., for the laying of 14,000 square yards of Dolarway pavement at New Rochelle.

Ottawa, Ont.—Tenders will be received up till October 3rd, 1913, for the construction of the substructures of a number of bridges. Plans and specifications may be obtained from the Department of Railways and Canals. L. K. Jones, Secretary.

Regina, Sask.—General repair work on the roadways and walks of the city is to be carried on at once, so that before the frost sets in the roads within the limits shall be in good condition.

Regina, Sask.—The city council has passed a by-law providing for new pavements aggregating in cost $650,782.46. The council has authorized also the construction of concrete sidewalks, totalling $119.427.24 in cost.

Toronto, Ont.—Tenders will be received up till October 7th, 1913, for the construction of asphalt, brick block, bitulithic and concrete pavements, for grading, concrete curbing, concrete walks and sewers. Plans and specifications may be obtained from the Chairman of the Board of Control, H. C. Hocken (Mayor).

+—Winnipeg, Man.—The contract has been awarded the DOMINION CONSTRUCTION CO., by the municipality of Assiniboia for the laying of granulithic sidewalk on Portage Avenue, from Albany Street to Deer Lodge. The contract was let for $5,021.

INDUSTRIAL WORKS.

Cap Chat, Que.—Tenders will be received up till October 22nd, 1913, for the construction of an extension to training pier at Cap Chat, County of Gaspe, Que. Plans and specifications may be obtained from J. T. Bertrand, Esq., District Engineer, Isle Verte, Que. Signed, R. C. Desrochers, Secretary, Public Works Department, Ottawa.

Edmonton, Alta.—A matter recently referred to the city council by Mr. J. D. McArthur, railroad contractor of Winnipeg, is the extension of the city's water mains to the yards of the E.D. and B.C Railway.

Fredericton, N.B.—A new suction dredge, constructed by James Fleming and Sons, St. John, at a cost of about $100,000, is being used in dredging for a channel 300 feet wide through the Oromocto shoals. The channel will be about a mile long and will improve greatly opportunities for navigation on the river.

▲—Halifax, N.S.—Tenders will be received up till October 15th, 1913, for the construction of about 6,500 lineal feet of quay wall, foundations of buildings, sewers, dredging of harbor and filling reclaimed areas. Plans and specifications may be obtained from the Department of Railways and Canals, Ottawa. L. K. Jones, Assistant Deputy Minister and Secretary.

Hamilton, Ont.—Mr. James Bain, chief engineer of the Beach pumping station, has devised a method of repairing the fusion vanes of the system instead of replacing them when worn out. The scheme has been approved by the Board of Control and other city officials, and, it is estimated, will save 75 per cent. on the cost of vanes.

+—Montreal, Que.—The contract has been awarded the RAYMOND CONCRETE PILING COMPANY by the Harbor Commissioners for the piling of two new sheds.

Montreal, Que.—The special dyke committee reported to the Verdun City Council recently that the dyke under construction will be completed by October 15th; that contracts had been placed for two pumps with a capacity of 15,000 gallons; and that plans for the pumping station had been approved. The work will be begun at once so that all will be in readiness for the spring.

Niagara Falls, Ont.—It is contemplated that there will be employment for 3,000 men on section No. 3 of the new Welland Canal, to be constructed by O'Brien and Doughey. About 200 men are already engaged in unloading large consignments of the plant which are arriving at Thorold, where the work is to commence.

▲—Ottawa, Ont.—Tenders will be received up till October 11th, 1913, for the construction of an extension to the Rifle Range at Kingston. Plans and specifications may be obtained from the Department of Militia and Defence, Ottawa. Eugene Fiset, Deputy Minister.

+—Ottawa, Ont.—The contract has been awarded MESSRS. REID AND ARCHIBALD, of Annapolis, N.S., for the construction of ice piers at that centre, the contract price being $34,700.

Ottawa, Ont.—Tenders will be received up till October 27th, 1913, for the construction of a training pier and revetment wall at Poupore, Labelle County, Que. Plans and specifications may be obtained from J. L. Michaud, Esq., District Engineer, Post Office Building, Montreal, Que. Signed, R. C. Desrochers, Secretary, Department of Public Works, Ottawa.

Ottawa, Ont.—Tenders will be received up till October 21st, 1913, for the construction of Wing Dam, No. 3, at the mouth of Woodward's Slough, Fraser River (Lower), B.C. Plans and specifications may be obtained from J. S. MacLachlan, Esq., District Engineer, Victoria, B.C. Signed, R. C. Desrochers, Secretary, Department of Public Works, Ottawa.

+—Ottawa, Ont.—A contract has been awarded the ISLAND DREDGING AND CONSTRUCTION COMPANY for a wharf at Dorchester, N.B., at a cost of $15,400.

+—Ottawa, Ont.—The contract was awarded to ANDREW McCONNELL for a wharf at Canoe, the contract price being $5,450.

Ottawa, Ont.—Tenders will be received up till October 29th, 1913, for the construction of harbor improvements at Wellington, Prince Edward Co., Ont. Plans and specifications may be obtained from J. G. Sing, District Engineer, Confederation Life Building, Toronto, or from the Department of Public Works. R. C. Desrochers, Secretary.

Prince Albert, Sask.—The department of Dominion Public Works has entered upon a scheme of protective work on the river front from the present wharf to the C.N.R. rail and traffic bridge. The work is the same type of construction as has been greatly used on the banks of the Mississippi, and which will be employed on a large scale along the river when other contemplated improvements have been carried out. Rows of close piling which will be tied in with caps and iron straps are being driven into the bed some ten or twelve feet from the present bank. The intervening space between the shore and the piling will be filled in with rock and gravel sufficient to render the work perfectly safe, and the municipal authorities are expected to do much piling in above this level and thus reclaim a considerable addition to the boulevard, which skirts the river front, and provide a pleasant slope to the water edge.

+—Sault Ste. Marie, Ont.—The contract has been awarded the SOO DREDGING AND CONSTRUCTION COMPANY by the Lake Superior Corporation for deepening the power channel of the Lake Superior Company from 18 feet to 21 feet, at a cost of $300,000. This is the beginning of extension work on the company's steel mills, which will, in the end, aggregate several millions of expense.

Sault Ste. Marie, Ont.—It is now evident that besides the new Welland Canal, the government will build another at the Soo. The new canal will be but another part accomplished in the carrying out of the scheme of improvement for navigation in Canada's great waterway of the St. Lawrence and the Great Lakes. The St. Lawrence canals also are to be deepened, making all the canals equal in facility and size for handling the greatly expanding traffic.

Ste. Anne de Monts, Que.—Tenders will be received up till October 22nd, 1913, for the construction of a wharf at Ste. Anne de Monts, County of Gaspe, Que. Plans and speci-

fications may be obtained from Chas. Chapais, Esq., District Engineer, Quebec, Que. Signed, R. C. Desrochers, Secretary, Department of Public Works, Ottawa.

St. John, N.B.—Mr. H. L. McGowan has asked the city commissioners to consider a grant to him of a reasonable commission to promote the establishment of a cement plant at Greenhead.

Summerland, B.C.—Tenders will be received up till October 31st, 1913, for the construction of a wharf at Summerland, B.C. Plans and specifications may be obtained from F. W. Aylmer, Esq., District Engineer, Chase, B.C. Signed, R. C. Desrochers, Secretary, Department of Public Works, Ottawa.

+—Vancouver, B.C.—It is announced by MESSRS. J. G. WHITE, eminent British harbor engineers, that they have secured the contract, involving about £6,000,000 sterling, for a scheme of harbor extension in Vancouver, where foreshore rights were granted recently by the provincial government to the Vanconver Harbor and Dock Extension Company. Twenty-five miles of dockage at Luln Island and Sea Island, and many miles for industrial sites and railway terminals will be provided. The government will have control over dockage rates, and all railways and steamship lines will be allowed equal privileges. By the agreement the government has the further right to purchase at an arbitrated value the works which the company will place at the disposal of the industrial world.

Victoria, B.C.—The new orange peel dredge, the fifth placed on the work of excavating a channel in the harbor, has been set in operation in the inner harbor.

▲—Welland, Ont.—Tenders will be received up till October 15th, 1913, for section No. 2, Welland Ship Canal. Plans and specifications may be obtained from L. K. Jones, Assist. Deputy Minister and Secretary, Department of Railways and Canals.

MISCELLANEOUS.

Brandon, Man.—The Everfresh Company, of Calgary, propose erecting a plant in this city, and have conferred with the city officials concerning the selection of a suitable site. Further arrangements with regard to the establishment of the industry will be made next month.

Calgary, Alta.—A site has been secured for the erection of a building for the Lewis File and Rasp Co., of Massillon, Ohio. The present plant of the company at Massillon is capable of turning out 100 dozen files a day, but more machinery is to be placed in the plant when re-established in Calgary, and an increased output will be the result.

Calgary, Alta.—The city is making a move to facilitate the location of manufacturers in Calgary. It is proposed to erect an industrial building for the housing of infant industries, and to that effect a by-law has been submitted to the ratepayers.

Calgary, Alta.—It was announced by Sir William Mackenzie, while in this city, that the C.N.R. will build a $500,000 depot in Calgary; and that the company approve the Calgary live stock scheme, will join with the C.P.R. and G.T.R. in financing the undertaking, and will do all in its power to make of the Calgary institution the greatest live stock market in Canada.

Fort William, Ont.—Plans for the foundation of the plant to be built by the Canadian Conley Frog and Switch Company at Port Arthur have been received by G. R. Duncan and Co. Tenders are being received and the work is expected to begin at once.

Fort William, Ont.—Before the close of this year, a pulp mill, the first to be located in western Ontario, which will manufactnre print paper only and will have a capacity of 100 tons a day, will be in operation.

Hamilton, Ont.—Plans have been completed by Mr. W. A. Edwards for an office building to be erected by the Royal Templars of Temperance at a cost of $22,000; and work on the structure is to begin immediately.

Lethbridge, Alta.—Plans prepared by William R. Perrin, abattoir engineers of Chicago and Toronto, for the packing plant to be erected by Delany's, Limited, have reached Lethbridge. After arrangements have been made with the city council, the company will let contracts for the erection of the basement of the building this fall.

+—Montreal, Que.—The contract has been awarded the DOMINION BRIDGE CO. for $3,200 worth of structural steel required by the city of Montreal.

Moose Jaw, Sask.—The contractors for the storage elevators have decided not to sublet the work on the excavations for the interior storage elevators, and it will be commenced at once. The material has been ordered and will be delivered to the site as soon as a spur track has been laid.

Moose Jaw, Sask.—Work has been started on the foundation of the distributing warehouse of George White and Sons, Limited, which will be removed here from the city of Regina. As much of the construction as will serve the needs of the company will be completed this winter, and in the spring of 1914, the work of erecting the remaining buildings called for by the agreement with the city will be undertaken.

Moose Jaw, Sask.—Plans for the interior storage elevator to be erected by the Dominion Government, have arrived in Moose Jaw. The elevator is to consist of 84 concrete tanks with 60 interspace tanks, and the space occupied by these will be 144 by 88 feet. The buildings are to be of fireproof construction, concrete and brick with reinforced steel. There will be receiving, cleaning and shipping plants with workhouse, track sheds, storage house, and drier plant, all to be completed and ready for operation by December 1st, 1914.

+—New Denver, B.C.—The contract has been awarded to A. DOUCETTE for the construction of a powder factory for the Steelite Explosives Company, of Nelson, at New Denver.

+—Newmarket, Ont.—The contract has been awarded to W. B. GRAHAM, of Toronto, by the Industrial Home Commissioners of York County, for the erection of a new Isolation Hospital, a short distance from the central building at Newmarket.

New York, N.Y.—The plans for the proposed $20,000,000 plant of the United States Steel Corporation, to be located at Ojibway, Ont., have not been completed, and building operations will not likely commence until next spring.

Ottawa, Ont.—A large building program is being set on foot for the capital. The printing bureau building will be torn down and replaced by a large modern building on a different site, while the present site will be utilized for the construction of a national library. The parliamentary library is at present too small to meet requirements. It is proposed further to enlarge the archives building, which also has become crowded.

Peterboro, Ont.—Tenders will be received up till October 4th, 1913, for the erection of a foundry building. Plans and specifications may be obtained from W. Blackwell, Architect, Water Street, Peterboro.

Saskatoon, Sask.—The newest industry to be incorporated in Saskatoon, is the Electric Cosy Cushion Company. The electric cosy cushion is an invention of Mr. Frank A. Cote; and Mr. J. Cahill, together with a number of local business men, plans to manufacture the devices of Mr. Cote as soon as a satisfactory laboratory and workshop have been properly fitted. A plant is already being used for the manufacture of the cosy cushion.

+—St. John, N.B.—The contract has been awarded JOHN S. METCALF CO., LIMITED, Constructing Engineers, Montreal, for approximately half a mile of Grain Shipping Conveyer Galleries at berths Nos. 5 and 6, Sand Point, West St. John, N.B. The cost is approximately $135,000.

+—Stratford, Ont.—The contract has been awarded MR. JOHN L. YOUNGS by the Canadian Allis-Chalmers Company, formerly the Stratford Mill-Building Company, for the construction of a new brick building to duplicate the present one. A new kiln and two cement sheds are also to be erected.

Toronto, Ont.—Tenders will be received up till October 7th, 1913, for the erection of an ornamental stone and iron gateway at the High Park Boulevard entrance to High Park, Toronto. Plans and specifications may be obtained from H. C. Hocken, chairman of the Board of Control.

Vancouver, B.C.—A site has been chosen on Shaughnessy Heights by Dominic Burns for a new Catholic cathedral. It is planned to erect a building at a cost of not less than $1,000,000.

The Departmental House for Mechanical Goods HAS ARRIVED

What the department store is to the general public our "Mechanical Goods Departmental House" is to the engineering and contracting field.

The public takes the efficient and time-saving merchandising methods of the department store as a matter of course. In the mechanical world we offer the same convenient service.

Why lose time "shopping" around town when you can buy anything you want and of a standard quality all under "one roof"?

Our business is divided into a number of departments in order that it may be handled most expeditiously and to the best interests of our customers.

In addition to the staple articles pertaining to each department we handle a great many specialties, some of which are listed below.

SCALE DEPARTMENT
- Fairbanks World-famous Scales, of all types and sizes

VALVE AND STEAM GOODS DEPARTMENT
- Fairbanks Brass and Iron Valves
- Pratt and Cady Valves
- Foster Reducing Valves
- American Steam Pressure Gauges
- Wainwright Joints
- Penberthy Oilers
- Strong Steam Traps
- Wainwright Heaters
- Burt Exhaust Heads
- American Safety Valves
- Trident Water Meters
- Palmetto Packing
- Durabla Packing
- Oster Stocks and Dies
- Tools and Fittings

ENGINE DEPARTMENT
- Fairbanks-Morse Oil Engines
- Fairbanks-Morse Marine Engines
- Fairbanks-Morse Tractors
- Farm Machinery
- Motor Boat Supplies
- Automobile Supplies

PUMP DEPARTMENT
- Fairbanks-Morse Steam Pumps
- Power Pumps
- Goulds Power Pumps
- Hand Pumps
- Combined Engines and Pumps
- Spraying Outfits
- Air Compressors
- Suburban Water Systems

ELECTRICAL DEPARTMENT
- Fairbanks-Morse Generators and Motors
- Edison Storage Batteries
- Suburban Lighting Outfits

MACHINERY DEPARTMENT
- Pratt and Whitney Tools
- Brown and Sharpe Tools
- McDougall Lathes
- Bertram Tools
- Machine shop tools of all kinds
- Wood Working Machinery

TRANSMISSION DEPARTM'T
- Fairbanks Wood Split Pulleys
- Universal Giant Shaft Hanger
- Skefko Ball Bearings
- Nicholson Couplings

RAILWAY AND SUPPLY DEPARTMENT
- Fairbanks-Morse Motor Cars
- Elwell-Parker Trucks
- Barrett Jacks
- Arthur Koppel Industrial Ry. Equipment
- Fairbanks-Morse Air Compressors
- Fairbanks-Morse Hoisting Engines
- Fairbanks Trucks
- Milburn Lights
- Smith Concrete Mixers

SMALL TOOL AND SUPPLY DEPARTMENT
- Pratt and Whitney Tools
- Brown and Sharpe Tools
- Yale and Towne Hoists
- Alundum Grinding Wheels
- Crystolon Grinding Wheels
- India Oil Stone
- Parker Vices
- Union Chucks

SAFE AND TYPEWRITER DEPARTMENT
- Dominion Safes and Vaults
- Noiseless Typewriters

TRUCK DEPARTMENT
- Mack Trucks (gasoline)

The Canadian Fairbanks-Morse Co. Limited

"The Departmental House for Mechanical Goods."

MONTREAL ST. JOHN QUEBEC OTTAWA TORONTO
WINNIPEG CALGARY SASKATOON VANCOUVER

Vancouver, B.C.—It is being negotiated to erect a $25,000 factory for a company manufacturing rubber goods on the north arm of the Fraser River, near Main St., South Vancouver. Among other goods to be manufactured are Kelly-Springfield tyres.

Vancouver, B.C.—The board of directors of the General Hospital have appointed a committee to draft a scheme for the enlargement of several buildings of the institution, with a view to increase of revenue for the hospital and also to further accommodation of both nurses and patients.

Vancouver, B.C.—An agreement for the acquisition by the Pacific and Great Eastern Railway for its terminal site of the Squamish Reserve, at Newport, has been closed between D'Arcy Tate, vice-president of the P.G.E. and Chief Joseph. However, the agreement will have to be submitted to the Indian commission for ratification.

Winnipeg, Man.—The United Steel Products Co., of New Jersey, U.S., has applied for permission to do business in Manitoba. It is believed that the organization is the selling corporation of the United States Steel Corporation, a company empowered to enter into all branches of the steel industry, selling and tributary industries, such as mining, smelting and dealing in lands. It is not known whether the steel trust intend to enter into manufacturing in Manitoba, or merely to open a selling agency in the province.

Winnipeg, Man.—Application has been made for a permit for the Manitoba new parliament buildings. The plans filed by Messrs. Thomas Kelly and Sons, call for the expenditure of $2,859,750 on the work.

Winnipeg, Man.—Tenders will be received up till October 16th, 1913, for the manufacture, delivery, installation and testing in the Grand Trunk Pacific shops at Transcona, of transformers and switching apparatus. Plans and specifications may be obtained from the Light and Power Department, 54 King Street. Signed, M. Peterson. Secretary, Board of Control, Winnipeg.

Winnipeg, Man.—Tenders will be received up till October 8th, 1913, for the supply and installation of the necessary apparatus for gas testing stations. Plans and specifications may be obtained from M. Peterson, Secretary, Board of Control, Winnipeg, Man.

CURRENT NEWS.

Brandon, Man.—Good progress is reported on the carbarns being erected here. The steel is being put in position, and the brickwork will in all probabilty be completed, as scheduled, by October 12th. The building will be ready for housing the cars by the end of November.

Calgary, Alta.—The warehouse and office building of the Cockshutt Plow Co., Limited, has just been completed. Calgary has now the most complete and up-to-date implement warehouse in Western Canada. The building is equipped with two large electric freight elevators of capacities of 3,000 pounds and 5,000 pounds respectively, while two spur tracks enable the company to handle six carloads of implements at once.

Calgary, Alta.—It is stated that a mining syndicate of American capitalists has ordered machinery to work four mines about 100 miles south of Calgary. The company is capitalized at $2,000,000. In order to place their coal on western markets, railroad connection will be necessary, which may have its terminal in Calgary.

Calgary, Alta.—The Alberta Packing Company will place before the mayor of this city the benefit which would be incurred to both city and province by the opening of large packing plants and abattoirs at Calgary. Every influence will be brought to bear on the council and ratepayers to pass a by-law allowing packing companies to open stockyards here.

Kenora, Ont.—Messrs. Arthur V. Arthur, Toronto, and A. F. Myers, Minneapolis, surveyors of the International Joint Waterways Commission, accompanied by Mr. Douglas N. McLean, of the Manitoba Hydrographic Survey, have visited Kenora to examine evidence relating to water levels and to inspect new gauges which have been established. Survey parties were also set in operation to examine places bordering on the shore of the lake, which might be affected by holding the water of the lake at various stages.

Kingston, Ont.—It is reported that the Canadian Northern Railway will have its Toronto-Kingston train in operation before the end of the year, and that as good time will be made by it as by the Grand Trunk.

London, Ont.—Many west end residents are of the opinion that the sum of $22,000 provided for breakwater purposes will be inadequate.

Montreal, Que.—Sir Philip Watts and Mr. J. H. Noble, two directors of the Armstrong-Whitworth Company, in company with Mr. M. J. Butler, consulting engineer for the company's new steel plant being constructed on the south side of the river, have inspected the work, and have expressed themselves well pleased with the progress shown, as well as with the site chosen. The plant consists of five large buildings. The water mains, important in the cooling process of the plant, have been laid, and there is every indication that by December, the entire plant will be roofed, and ready for the installation of machinery.

Ottawa, Ont.—An arrangement satisfactory to shippers and other business interests concerned and the railway systems, brought about through the intervention of the Board of Railways' Commissioners, provides that the railways continue their cartage service in eastern cities from September 30th to December 31st. However, the rate will be increased by half a cent a hundred pounds, with a minimum of 20 cents.

Port Nelson, Hudson Bay.—180,000 feet of large bridge timber have been landed by the freighters, and it is the intention of the Government to rush the loading of the supplies so that a full start may be made with steel next spring.

Saskatoon, Sask.—The city council have asked the Dominion Grain Commissioners, if they will consider new propositions in regard to the selection of a site for the new interior storage elevator. The chief grain commissioner, R. Magill, Esq., is opposed to changing the site already decided upon, since construction would be delayed. However, the matter is to be placed before the entire board of grain commissioners.

Sault Ste. Marie, Ont.—The first step towards the linking of Sault Ste. Marie and St. Ignace, which would give the Grand Trunk a route from Southern Michigan right to the Grand Trunk Pacific, over the line of the Algoma Central, has been successfully taken. Mr. W. C. Franz, vice-president and general manager of the transportation lines of the Lake Superior Corporation, has announced that the Algoma Central Railway has secured running rights over the International bridge, which spans the St. Mary's River rapids.

Toronto, Ont.—The Board of Control have been asked by the Hydro-Electric Commission to approve an additional capital expenditure of $700,000, for extensions to the system.

Vancouver, B.C.—Prominent railway officials in the persons of Col. E. Moody, passenger traffic manager of the Pennsylvania line, and Mr. Z. L. A. Thompson, district passenger agent at Chicago, have recently visited Vancouver.

Victoria, B.C.—Mr. Walter Luney, of Luney Brothers, contractors for the excavation of the site of the Hudson's Bay Company's new mammoth store, hopes to have that part of the work completed within the time prescribed. Owing to the exceptional size of the site, it is estimated that 24,000 yards of material will have to be removed, and that two-thirds of this will be rock. However, a large compressor plant has been secured, and Mr. Luney is confident that the blasting of the rock will not delay the completion of the work beyond the three months' limit.

TRADE ENQUIRIES.

The following were among the inquiries relating to Canadian trade received at the office of the High Commissioner for Canada, 17 Victoria Street, London, S.W.:—A manufacturers' agent at Odessa desires to get into communication with Canadian manufacturers of agricultural implements and other goods, for which there would be a market in Russia.—

From the branch for city trade inquiries, 73 Basinghall Street, London, E.C.:—A Glasgow firm who are open to contract for regular supplies of pulp board, invite quotations from Canadian manufacturers. A London firm desire the addresses of Canadian manufacturers of wrought iron tubes, in a position to fill export orders. A London firm are open to receive offers from Canadian producers of turpentine and of oils.

Insurance Engineering

We maintain a skilled force of engineers and inspectors to advise in regard to the insurance of industrial undertakings.

We offer our services as consultants to engineers and architects who have charge of industrial construction. We have a thorough knowledge of fire protection and the many matters which govern insurance rating.

Manufacturers are invited to permit us to make an inspection and to let us make suggestions regarding fire protection which will add security and also likely more than pay for themselves through reduced insurance rates.

Insurance may be placed through our firm in the same manner as it would be through other insurance brokerage firms. The service rendered—in most cases without cost to our clients—by our staff of inspectors and engineers makes it profitable for owners who are placing insurance on industrial undertakings to place the insurance through our firm.

Should Take an Important Place

From the Dean of an Engineering College:—

"I have been favorably impressed with the ground covered, with the general make-up and the ease of finding any particular class of material. It seems to me that it should immediately take a very important place in the library of every civil engineer."

Sewers must carry the sewage quickly and surely to the distant point of disposal.

Therefore they must not only be laid in a proper gradient, but they must also be of a smooth material that will not cause delays in the flow of the sewage. Smooth, round, perfect, salt-glazed vitrified pipe, without blisters or scales and without cracks—in short, MIMICO PIPE—is absolutely required for a perfect sewer. It will pay you to get in touch with us.

TENDERS CALLED FOR

DEPARTMENT OF MILITIA AND DEFENCE. KINGSTON, ONT.—RIFLE RANGE.

NOTICE TO CONTRACTORS.

Sealed tenders, marked on the envelope "Tender for additions to Rifle Range, Kingston, Ont.," and addressed to the Director of Contracts, Militia Headquarters, Ottawa, will be received until noon, 11th October, proximo, for the construction of an extension to the Rifle Range at Kingston, Ont.

Plans and specifications may be seen and full information obtained at the offices of the Officer Commanding the 3rd Divisional Area, Kingston Ont., and the Director General of Engineer Services, Headquarters, Ottawa.

Tenders must be made on forms supplied by the Department and each tender must be accompanied by an accepted cheque on a Canadian Chartered Bank for 10 per cent. of the amount of the tender, payable to the order of the Honorable the Minister of Militia and Defence, which amount will be forfeited if the party tendering declines to enter into or if the Contractor fails to complete his contract in accordance with the tender.

The Department does not bind itself to accept the lowest or any tender.

EUGENE FISET, Colonel,
Deputy Minister.

Department of Militia and Defence,
Ottawa, September 18, 1913.

Newspapers will not be paid if they insert this advertisement without authority from the Department.

H.Q. 18-114-2.—48030.

DEPARTMENT OF RAILWAYS AND CANALS, CANADA.

CANADIAN GOVERNMENT RAILWAYS.

Halifax Ocean Terminals Railway, Halifax, N.S.

Sealed tenders addressed to the undersigned and endorsed "Tender for docks, First Unit, Contract No. 3, Halifax Ocean Terminal," will be received at this office until twelve o'clock noon, Wednesday, the fifteenth day of October, 1913, for the construction of about 6,500 lineal feet of quay wall, foundations for buildings, sewers, dredging of harbor to a depth of 45 feet at low water, and filling reclaimed areas.

Plans and specifications and form of tender may be seen and full information obtained at the office of the General Manager, Moncton, N.B., at the office of the Chief Engineer of the Department of Railways and Canals, Ottawa, and at the office of the Superintending Engineer, Halifax, N.S.

The right is reserved to reject any or all tenders.

By order, L. K. JONES,
Assistant Deputy-Minister and Secretary.

Department of Railways and Canals,
Ottawa, September 2nd, 1913.

DEPARTMENT OF RAILWAYS AND CANALS, CANADA.

WELLAND SHIP CANAL.

SECTION No. 2.

NOTICE TO CONTRACTORS.

Sealed Tenders, addressed to the undersigned and marked "Tender for Section No. 2. Welland Ship Canal," will be received at this office until 12 o'clock noon on **Wednesday, October 15th, 1913.**

Plans, specifications and form of contract to be entered into can be seen on or after this date at the office of the Chief Engineer of the Department of Railways and Canals, Ottawa, and at the office of the Engineer in Charge, St. Catharines, Ontario.

Copies of plans and specifications may be obtained from the Department on the payment of the sum of fifty dollars. To bona fide tenderers this amount will be refunded upon the return of the above in good condition.

Parties tendering will be required to accept the fair wages schedule prepared or to be prepared by the Department of Labor, which schedule will form part of the contract.

Contractors are requested to bear in mind that tenders will not be considered unless made strictly in accordance with the printed forms, and in the case of firms, unless there are attached the actual signature, the nature of the occupation, and place of residence of each member of the firm.

An accepted bank cheque on a chartered bank of Canada for the sum of $150,000.00 made payable to the order of the Minister of Railways and Canals, must accompany each tender, which sum will be forfeited if the party tendering declines entering into contract for the work, at the rates stated in the offer submitted.

The cheque thus sent in will be returned to the respective contractors whose tenders are not accepted.

The cheque of the successful tenderer will be held as security, or part security, for the due fulfilment of the contract to be entered into.

The lowest or any tender not necessarily accepted.

By order,
L. K. JONES,
Asst. Deputy Minister and Secretary.

Department of Railways and Canals,
Ottawa, 22nd September, 1913.

Newspapers inserting this advertisement without authority from the Department will not be paid for it.—48056.

GAS AND GASOLINE ENGINE, ten horsepower, Fairbanks-Morse; excellent condition; bargain. Can be seen in operation. Review Company, Bridgeburg, Ont.

FOR SALE.—Three to five-ton tandem steam road roller. Machine is in excellent condition and will be sold cheap for cash. Address Box 146, *The Canadian Engineer*, Toronto.

WANTED.—Second-hand locomotive crane. Must be in good working order and capable of lifting 8 tons at a radius of 50 feet. Address Box 148, *The Canadian Engineer*, 628 Board of Trade Building, Montreal.

FOR SALE.—Contractor's machinery, including hoisting engine, 16 dump cars, 1 Ransome mixer, 21 concrete buckets. Address Box 150, *The Canadian Engineer*, Toronto.

Tenders Called For

Sealed tenders addressed to the undersigned, and endorsed "Tender for Harbor Improvements at Wellington, Ont.," will be received at this office until 4 p.m., on Wednesday, October 29, 1913, for the construction of Harbor Improvements at Wellington, Prince Edward County, Ontario.

Plans, specification and form of contract can be seen and forms of tender obtained at this Department and at the offices of J. G. Sing, Esq., District Engineer, Confederation Life Building, Toronto, Ont., and on application to the Postmaster at Wellington, Ont.

Persons tendering are notified that tenders will not be considered unless made on the printed forms supplied, and signed with their actual signatures, stating their occupations and places of residence. In the case of firms, the actual signature, the nature of the occupation, and place of residence of each member of the firm must be given.

Each tender must be accompanied by an accepted cheque on a chartered bank, payable to the order of the Honorable the Minister of Public Works, equal to ten per cent. (10 per cent.) of the amount of the tender, which will be forfeited if the person tendering decline to enter into a contract when called upon to do so, or fail to complete the work contracted for. If the tender be not accepted the cheque will be returned.

The Department does not bind itself to accept the lowest or any tender.

By order,

R. C. DESROCHERS,
Secretary.

A 40-TON LOAD.

The illustration shows an interesting use of a contractor's haulage outfit in transporting a huge electric train in Pittsburg, recently. The road freight car is one of the Buffalo Pitts Company, Buffalo, N.Y., standard 20-ton capacity cars used by contractors in their work.

The car is built with wooden frame, with steel facing and steel braces. The axles are 3½-inch solid steel. The wheels

A 20-ton road freight car, put to unusual service.

are also of steel, and are 48 inches high, with a 14-inch tire face. The car is equipped with a patent reversible gear that makes every wheel track perfectly, and enables steering a number of these cars en train either front or back with ease.

Contractors are using haulage outfits for every conceivable kind of work outside their regular field of application. The above company build many types of special cars on order and furnish their different types of standard cars in 5-ton, 10-ton, and 20-ton capacity with patent reversible gears, so that they may be coupled in one train.

The tractor shown is also of Buffalo Pitts Company make.

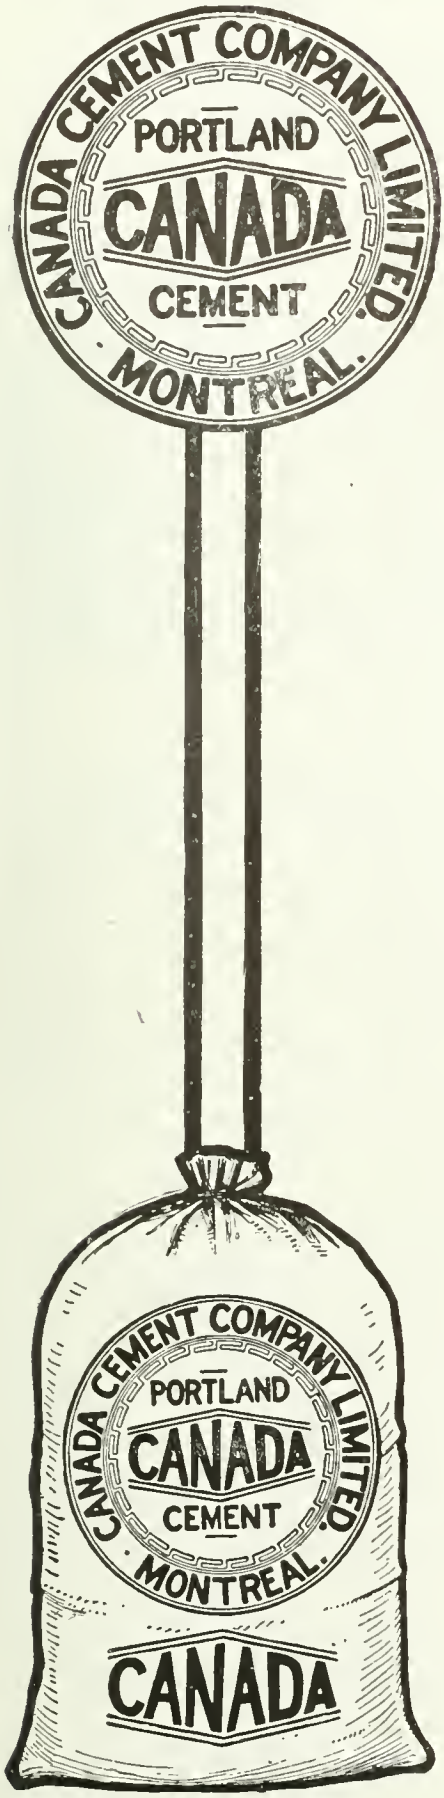
Sangster, both of St. Catharines, T. R. Hinds, Toronto.

PERMANENCE—



an ideal that is now attainable

THE superiority of concrete over all other materials for the building of permanent structures is now generally admitted.

The next step towards ideal construction, is to realize that for satisfactory concrete work, it is necessary to use a cement that is uniformly high-grade

CANADA Portland CEMENT

is the selection of the leading engineers, architects and contractors. Their experience has proved that in this brand they can obtain a certainty of success.

With concrete coming into more and more general use for the construction of buildings, bridges, viaducts and highways, it is vitally important that those in authority on such matters should select the best materials obtainable.

Use the cement that our best architects and engineers have selected for their most important undertakings. Select Canada Cement — it costs no more than any others.

ELECTRIC FURNACE.—The proprietors of Canadian Letters Patent No. 134,772 of 1911, are prepared to sell, or license Canadian manufacturers to work in Canada, this patent, which relates to a furnace to be used for the refining of steel or for other refining or smelting operations. Address, International Acheson Graphite Co., Niagara Falls, Ont.

PATENT NOTICE.—Any one desiring to obtain the invention covered by Canadian Patent No. 136182, granted on October 17th, 1911, to G. W. Clarke, T. B. Eastman and F. M. Wright, of California, U.S.A., for matrix plate, may do so upon application to the undersigned, who are prepared to supply all reasonable demands on the part of the public for the invention and from whom full information may be obtained. Fetherstonhaugh and Smart, 53 Queen Street, Ottawa, Canada. Russel S. Smart, Resident.

PATENT NOTICE.—Any one desiring to obtain the invention covered by Canadian Patent No. 136018, granted on October 3rd, 1911, to F. M. Walter, of Bournemouth, Hants, England, for mowing and plowing machine, may do so upon application to the undersigned, who are prepared to supply all reasonable demands on the part of the public for the invention and from whom full information may be obtained. Fetherstonhaugh and Co., 53 Queen Street, Ottawa, Canada. Russel S. Smart, Resident.

MONTREAL MARKET LETTER.

The effect of the new tariff laws to come into force in the United States shortly, is the most interesting feature of the iron and steel market; yet the market seems to give very few signs on what must prove a great change. A despatch from the United States says:—"For some time foreign bars and other products have been quoted for Pacific coast delivery at prices contingent on the proposed low duties going into effect. Some American inquiries for European billets are reported. Like recent inquiries from this side for English pig iron, they are more an effort to find what could be done than actually to buy."

There has been considerable disappointment throughout the United States owing to the lack of the placing of contracts for steel products of various kinds. It is now thought that the first of the large rail orders for next year must shortly be placed. When these orders begin to come along a good idea of the requirements of the railways will be obtained. The outlook at the moment does not seem to be particularly encouraging. Steel bars are holding firm and mills seem to have been taking orders at prices subject to revision in case of a decline and up to the present seem to have been able to hold the price at 1.40c. basis. Iron bars are holding about steady. Some orders for structural work have been coming out and the supply is fairly large.

The pig iron market appears to be holding its own fairly well. There was a slight firming of prices about a month ago and this level has been maintained. Contracts are already being placed for the first quarter of 1914, although the volume up to the present seems to be small. Producers of iron, fortunately, are able to purchase coke at a slight reduction, and this will help out considerably.

Iron and steel circles in Montreal are particularly interested in the outcome of the receivership for the Canada Iron Corporation. From all that can be learned, the difficulty has arisen through operating the pig iron furnace at a loss. The company has apparently been unable to meet competitive prices. The other departments of the corporation are said to have been operated at a profit.

Orders for iron and steel have been coming out as well as expected. There has been some falling off in business, but several companies report that they expect the most remunerative year in their history. They are, however, beginning to fear the effects of the lowering of the American tariff, inasmuch as it now seems to be pretty generally admitted that this will bring down costs in the United States and thus create more competition in the Canadian market

MARKET CONDITIONS

Montreal, September 27th, 1913.

Bar Iron and Steel.—Trade is reported active. Bar iron, $2.10 per 100 pounds; best refined horseshoe, $2.35; forged iron, $2.25; mild steel, $2.20; sleigh shoe steel, $2.20 for 1 x ⅜ base; tire steel, $2.30 for 1 x ⅜ base; toe caulk steel, $3; machine steel, iron finish, $2.25.

Cement.—Canadian cement is quotable, as follows, in car lots, f.o.b., Montreal:—$1.35 to $1.40 per 350-lb. bbl., in cotton bags, adding 10c. for each bag. Good bags repurchased at 10c. each. Paper bags cost 25 cents extra, or 10c. per bbl. weight.

Chain.—The market is quoted per 100 lbs. as follows:—¼-in., $5.65; 5/16-in. $4.70; ⅜-in., $4.00; 7/16-in., $3.65; ½-in., $3.45; 9/16-in., $3.45; ⅝-in., $3.35; ¾-in., $3.25; ⅞-in., $3.15; 1-in., $3.05.

Explosives and Accessories.—Dynamite, 50-lb. cases, 40 per cent. proof, 15c. in single case lots, Montreal; 50 per cent., 16½c., and 60 per cent., 18c. Blasting powder, 25-lb. kegs, A, $1.85, and B, $2.35 per keg. Special quotations on large lots of dynamite and powder. Detonator caps, case lots, containing 5,000, 75c. per 100; double strength, $1, and broken lots higher; electric blasting apparatus:—Batteries, 1 to 10 holes, $13.50; 1 to 10 holes, $20.50; 1 to 50 holes, $41. Wire, leading, 1c. per foot; connecting, 50c. per lb. Fuses, platinum, single strength, per 100 fuses:—4-ft. wires, $3; double strength, $3.50; 6-ft. wires, $3.54, and double, $4.04; 8-ft. wires, $4.08, and double, $4.58; 10-ft. wires, $5, and double, $5.12.

Galvanized Iron.—The market is steady. Prices, basis, 28-gauge, are:—Queen's Head, $4.40; Colborne Crown, $4.20; Apollo, 10¼ oz., $4.30. Add 25c. per 100 lbs. to above figures for less than case lots; 26-gauge is 25c. less than 28-gauge, American 28-gauge and English 26 are equivalents, as are American 10¼ oz., and English 28-gauge.

Galvanized Pipe.—(See Pipe, Wrought and Galvanized)

Iron.—Following prices are on dock. No 1 Summerlee, $22.50 per ton, selected Summerlee, $22; soft Summerlee, $21.50 per ton. No. 3 Middlesboro irons are about $19 per ton. Carron iron, number for number and grade for grade is quoted about the same price as Summerlee. Canadian Iron sells here at about $19.25 to $19.50 per ton, on track.

Lath.—See Lumber, etc.

Lumber, Etc.—Prices on lumber are for car lots, to contractors, at mill points. Red pine, mill culls out, $20 to $22 per 1,000 feet; white pine, mill culls, $20. Spruce, 1-in. by 4-in. to 6-in., $21; 1 x 7 to 9, $24 per 1,000 ft.; mill culls, $18. Hemlock log run, culls out, $19. Railway Ties, Standard Railway Ties, hemlock or cedar, 50 to 55c. each. Telegraph Poles: seven-inch top, cedar poles, 25-ft. poles, $2 each; 30-ft., $3.75; 35-ft., $4.50 each, 40-ft., $6; 45 to 50, 16c. per foot. Laths: Quotations per 1,000 laths, at manufacturers' points. Spruce, 4-ft x 1½-in., mill run, $3 to $3.25; pine, 4-ft. x 1½-in., mill run, $3.25 to $3.75. Shingles: Cedar shingles, same conditions as laths, X, $2.10; XX, $2.40; XXX, $2.80.

Pipe.—Cast Iron.—The market is dull and rather easy:—$34 for 6 and 8-inch pipe and larger; $35 for 4-inch at the foundry. Pipe, specials, $3 per 100 pounds. Gas pipe is quoted at about $1 more than the above.

Pipe.—Wrought and Galvanized.—Demand is fair and the market steady:—¼-inch $5.50, with 63 per cent. off for black, and 48 per cent. off for galvanized; ⅜-inch, $5.50, with 63 per cent. off for black, and 48 per cent. off for galvanized; ½-inch, $8.50, with 69 per cent. off for black, and 59 per cent. off for galvanized. The discount on the following is 72½ per cent. off for black and 62½ per cent. off for galvanized; ¾-inch, $11.50; 1-inch, $16.50; 1¼-inch, $22.50; 1½-inch, $27. On the following the discount is 72½ per cent for black and 62½ per cent. for galvanized:—2-inch, $36; 2½-inch, $57.50, and 3-inch $75.50; 72½ per cent. off for black, and 62½ per cent. of for galvanized; 3½-inch $95; 4-inch $1 08.

Toronto, October 1st, 1913.

The following are the wholesale prices for Toronto, where not otherwise explained, although for broken quantities higher prices are quoted.

Axes.—Standard makes, double bitted, $6 to $10; single bitted, per dozen, $7.50 to $9.

Bar Iron.—$2.25 base, per 100 lbs., from stock to wholesale dealer. In enormous demand.

Bar Mild Steel.—Per 100 lbs., $2.25. Sleigh shoe and other take same relative advance.

Boiler Plates.—¼-inch and heavier, $2.20. Boiler heads 25c. per 100 pounds advance on plate. Tank plate, 3-16-inch, $2.40 per 100 pounds.

Boiler Tubes.—Orders continue active. Lap-welded, steel, 1¼-inch, 10c.; 1½-inch, 9c. per 10-ft.; 2-inch, $8.50 to $9; 2¼-inch, $10; 2½-inch, $10.50; 3-inch, $12.10; 3½-inch, $15; 4-inch, $19.

Bricks.—In active movement. The price is $11.50 for grey stock, $12 for red stock. Don Valley pressed brick are in request. No. 1 dry pressed and buff bricks are worth $18 delivered and $17 at works per 1,000. Port Credit Brick Company's prices are as follows, f.o.b., Port Credit: Wire cut bricks, $10 per M.; pressed bricks, $13 to $15 per M., three grades.

Broken Stone.—Lime stone, good hard, for roadways or concrete, f.o.b., quarries 70 to 75c. per ton of 2,000 lbs., either 1-inch, 10c., 2-inch, or larger, price all the same. Rubble stone, 55c. per ton, Schaw station, and a good deal moving. Broken granite is selling at $3 per ton for good Oshawa, or Quebec Province. At Washago, $2.50 per ton for small, and $1.15 for large, freight to Toronto, 60 cents.

Cement.—Demand very brisk, and prices maintained. In large quantities the price is $1.50, sacks 40c. extra; car lots $1.55, sacks extra; city dealers ask $1.85, sacks extra. Prices remain firm.

Copper Ingot.—The market is lower at 15¾ to 16c., sheet copper case (16 oz. soft), 22½c. to 24½c. per lb.

Detonator Caps.—75c. and $1 per 100; case lots, 5,0000, 20 per cent. off.

Dynamite.—The prices for this explosive vary according to the percentage of nitro-glycerine compounded in the mixture and are as follows, f.o.b., Toronto:—40 per cent., 16¾ cents pound, 1 to 9-case lots, 50 lbs. to case. For each additional 10 per cent. nitro-glycerine add 1½c. per hundred. For 10-case lots and over deduct ¼ cent. For 20-case lots and over deduct 1 cent. For 40-case lots and over deduct 1¼ cent.

Fuses.—Electric Blasting.—Double strength, $3.50 per hundred, advance 54c. per hundred for each 2-in. wire additional. Single strength, $3 per hundred, advance 54c. per hundred for each 2-in. wire additional.

Iron Chain.—¼-inch, $5.75; 5-16-in, $5.15; ⅜-inch, $4.15; 7-16-inch, $3.95; ½-inch, $3.75; 9-16-inch, $3.70; 5-8-inch, $3.55; ¾-inch, $3.45; ⅞-inch, $3.40; 1-inch, $3.40 per 100 lbs.

Iron Pipe.—Quotations are changed as follows:—Black pipe, ¼-inch, $2.04; ⅜-inch, $2.04; ½-inch, $2.72; ¾-inch, $3.16; 1-inch, $4.54; 1¼-inch, $6.19; 1½-inch, $7.43; 2-inch, $9.90; 2½-inch, $15.80; 3-inch, $20.75; 3½-inch, $26.13; 4-inch, $29.70; 5-inch, $40.60; 6-inch, $52.64. Galvanied Pipe, ¼-inch, $2.86; ⅜-inch, $2.86 ½-inch, $5.57; ¾-inch, $4.31; 1-inch, $6.19; 1¼-inch, $8.44; 1½-inch, $10.13; 2-inch, $13.50; 2½-inch, $21.56; 3-inch, $28.31.

Lead.—Firmer, $5.25 to $5.50.

Pig Iron.—We quote Clarence at $24 for No. 3; Cleveland, $24; Summerlee, $27; Hamilton quotes $22; Midland, No. 1, $22; No. 2, $21.50. There is considerable enquiry for 1912.

Pitch and Tar.—Pitch, unchanged at 75c. per 100 lbs. Coal tar, $3.75 per barrel.

Roofing Slate.—Most of the slate used in Canada comes from Pennsylvania or Maine, the Canadian supply being sleeker and mostly from the Rockland quarries of the Eastern Townships, in Quebec. There is a great variety of sizes and qualities, so that it is difficult to indicate prices. But Jackson Bangor, 10 x 16 may be quoted at $6.75 per square of 100 square feet f.o.b. cars, Toronto; seconds, 50c. less. Mottled, $8; green, $8, with a prospect of advance. Dealers are fairly busy.

Sand.—Sharp, for cement or brick work, $1.15 per net yard f.o.b., cars, Toronto siding.

Sewer Pipe.—

	4-in.	6-in.	9-in.	12-in.	24-in.
Straight pipe; per foot	$0.25	$0.40	$0.65	$1.00	$ 5.05
Single junction, 1 or 2 ft. long	1.00	1.60	2.60	4.00	15.00
Double junctions	1.25	2.00	3.25	5.00	16.05
Increasers and reducers	....	1.60	2.60	4.00	13.00
P. & H. H traps	2.00	3.20	6 50	15.00	.....
Bends	0.75	1.20	1.95	3.00	9.75

Above is the October list as changed. The retail price is less 65 per cent. off these figures on all sizes, 9 inches and under or less 60 per cent. off these figures on anything over 9 inches. For car-loads a greater discount.

Steel Beams and Channels.—Active.—We quote:—$2.65 to $3 cut to length per 100 lbs., according to size and quantity; angles, 1½ by 3-16 and larger, $2.50 to $2.75; tees, $2.75 to $3 per 100 pounds. Extra for smaller sizes of angles and tees.

Sheet Copper.—22c. per lb.

Sheet Steel.—American Bessemer, 10-gauge, $2.75; 12-gauge, $2.80; 14-gauge, $2.50; 17, 18, and 20-gauge, $2.75; 22 and 24-gauge, $2.80; 26-gauge, $2.85; 28-gauge, $3. A very active movement is reported at unchanged prices.

Sheets, Galvanized.—Apollo Brand.—Sheets, 6 or 8 feet long, 30 or 36 inches wide; 10-gauge, $3.00; 12-14-gauge, $3.00; 16, 18, 20, $3.30; 22-24, $3.40; 26, $3.50; 28, $3.90; 29, $4.10; 10¾, $4.10 per 100 pounds. Fleur de Lis, 28-gauge, $4.25; 26, $4.05 per 100 lbs. Active and firm at these prices.

Tin.—The combination seems to hold, and the price, 45 to 50c., lower.

Tool Steel.—Jowett's special pink label, 10½c. Cammel-Laird, 16c. "H.R.D." high speed tool steel, 65c.

Tank Plates.—3-16-inch, $2.40 per 100 lbs.

Zinc.—Spelter.—Good demand, and the feeling strong. Light stock; excellent demand. We quote very firm at $6 to $6.50 per cwt.

Winnipeg, September 30th, 1913.

Anvils.—Per pound, 11½ to 12½c.; Buckworth anvils, 80 lbs. and up, 10¾ to 10½c.; anvil and vise combined, each $5.50.

Bar Iron.—$2.50 base.

Bars.—Crow, $4.50 per 100 pounds.

Beams and Channels.—$3 to $3.10 per 100 up to 15-inch, 4, 30, 41, 50, 118, 119, 172, 132, 145, 176.

Brick.—Kiln run per M, $13; sewer per M, $14; chimney per M, $14; veneer per M, $15; pressed per M, $25 to $50; enameled per M, $100; sand lime per M, $13.

Cement, Portland.—$2.40 to $2.50 per barrel.

Chain.—Coil, 3-16-in., $10; ¼, $7.25; 5-16, $5.85; ⅜, $5; 7-16, $4.75; ½, $4.50; 9-16, $4.50; ⅝, $4.40; ¾, $4.25. Logging, 5-16, 6½c.; ⅜, 5½c. Tie out, 70 and 10 per cent.

Copper.—Tinned, boiler, 26½c., planished 29½c.; boiler and T. K. plts, plain, tinned, 45 per cent discount.

Dynamite.—$11 to $13 per case.

Galvanized Iron.—Apollo, 10¾, $4.80; 28, $4.60; 26, $4.20; 22, $4.10; 24, $4.10; 20, $4; 18, $3.95; 16, $3.90; Queen's Head, 28, $4.90; 26, $4.70; 24, $4.30; 22, $4.30; 20, $4.10 per cwt.

Iron.—Swedish iron, 100 lbs., $4.75 base; sheet, black, 14 to 22 gauge, $3.75; 24-gauge, $3.90; 26-gauge, $4, 28-gauge, $4.10. Galvanized—American, 18 to 20-gauge, $4.40; 22 to 24-gauge, $4.65; 26-gauge, $4.65; 28-gauge, $4.90; 30-gauge, $5.15 per 100 lbs. Queen's Head, 22 to 24-gauge, $4.65; 26-gauge English, or 30-gauge American, $4.90; 30-gauge American, $5.15; Fleur de Lis, 22 to 24-gauge, $4.50; 28-gauge American, $4.75; 30-gauge American, $5; bar, $2.50 base.

Pipe.—Iron, black, per 100 feet, ⅜-inch, $2.40; ½-inch, $2.35; ¾-inch, $3.35; ¾-inch, $4; 1-inch, $5.75; 1¼-inch, $7.80; 1½-inch, $9.35; 2-inch, $12.50; galvanized—½-inch, $4.15; ¾-inch, $5 20; 1-inch, $7.55; 1¼-inch, $10.25; 1½-inch, $12.25; 2-inch, $16.40. Lead, 7 60 per cent., full coil.

Pitch.—Pine, $6.50 per barrel, in less than barrel lots, 4c. per lb.; roofing pitch, $1 per cwt.

Steel Plates, Rolled.—3-16-in., $3.35 base; machinery, $3 base; share, $4.50 base; share crucible, $5.50, cast share steel, $7.50; toe calk, $4.50 base; tire steel, $3 base; cast tool steel, lb., 9 to 12½c.

Tool Steel.—8½ to 15c. per pound.

POINTS IN BRICKS AND BRICK CONSTRUCTION

STANDARDIZATION OF BRICK IS TIMELY—LOSS OF STRENGTH IN BRICKWORK DUE TO FROGS—LACK OF UNIFORMITY IN SIZES—CLASSIFICATION OF BRICKS—BRICK MORTARS—SUGGESTED IMPROVEMENTS OVER PRESENT PRACTICE

By ROBT. J. MARSHALL, B.A.Sc.,

Department of Applied Mechanics, University of Toronto

THE commonest building material used to-day in factory construction is the old-fashioned brick. The art of brick-making and brick-laying is a very ancient trade. One of the causes of trouble, according to Biblical record, between the Israelites and Egyptians had to do with the making of bricks, and from this we are at liberty to infer that brick-laying, as well as brick-making was a very ancient craft. Some of the oldest ruins of the Orient remain to-day as monuments of the skill of these men.

It follows, therefore, that when a student of present-day building materials discovers a desire to investigate all parts of his subject, he ought to be fully warned about the seriousness of tampering with history. The age of these ancient crafts and the history surrounding them, make the art of the brickmaker and bricklayer venerable and exempt from the invasion of recent learning. They seem to have been the barrier which has prevented the thorough examination such as all the newer materials have had to undergo in recent years.

Brick is the last of the commonest of the building materials to be standardized. The investigation and subsequent standardization of the brick crafts are being undertaken by the American Society for Testing Materials, and this society may be depended upon to carry on the work in the same thorough way that they have done in the case of steel and concrete.

The reasons for the present revision of the rules of brick-making and brick-laying is that present methods are uneconomical, inefficient and careless. The necessity of economical consideration is the result of the present tendency to build high buildings. The inefficiency is seen in the ineffective distribution of material; and the carelessness is everywhere evident in the business.

In recent years factory and office buildings have grown from the old three, four and five-story type to the present ten, fifteen and twenty-story buildings. If brick buildings were restricted to the old type there would be no pressing reason for a change. But office and factory buildings are so expensive to erect at present that prospective builders are compelled to give careful consideration to economy in their building material. A good brick building would suit a great many such builders if designed on an economical principle, allowing an adequate factor of safety.

Economical designs are not now possible under our very conservative building by-laws. But the by-laws are not properly to blame, for back of them there are good and sufficient reasons for the conservation; and those reasons are the direct result of carelessness all through the brick-making and building trades.

In the last thirty years, the rules governing the use of all our building materials have undergone, or are undergoing, revision. Technical and economical considerations have led to new, more accurate and appropriate uses. Processes of manufacture are yearly improving the uniformity of most building materials. The result of these improvements is a more reliable material. The more reliable it is, the closer may the safe working

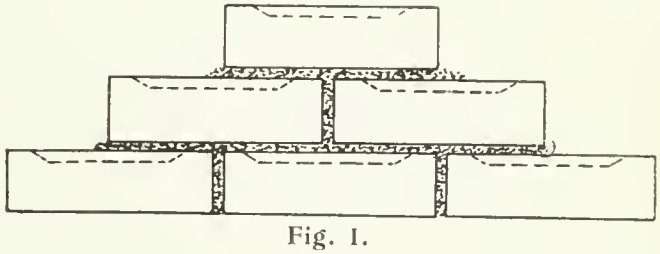

Fig. 1.

load be figured to the ultimate strength of the material. As a result of the above-mentioned improvements, safety factors are becoming more clearly defined and they will continue to diminish as materials improve in reliability.

The commonly accepted safety factor for steel is 4; for concrete, 5 to 6; for timber, 7+; and for brick, 10+. These empirics are an index of uniformity and reliability, and indicate in a general way the channels in which manufacturers have made the most progress. The high safety factor is very necessary in timber, owing to natural defects, such as knots, cross-graining, etc., but where a man commences with the raw material and makes a brick wall by his own process, it seems to be a misjudgment to lay the blame for all the defects of the resultant to natural causes.

The Effect of the Frog in Brickwork.—The first point at issue is the use of the frog in bricks. The commonly-accepted theory, with regard to the frog in a brick, is that it is the bond which resists the possible horizontal shearing stresses. If Fig. 1 is examined, it will be seen

that the mortar between the bricks is bonding the frogged surface of the lower brick to the flat surface of the upper course. Failure from such shearing stresses will take place across the weakest horizontal section, which would be in this case the sections at the flat surface. Therefore, the resistance to shear between the bricks depends upon the bond between the mortar and the flat surface, hence it is obvious that equal resistance to shear would be obtained if the surfaces were flat below and flat above. In practice the Canadian bricklayer spreads his mortar on the preceding course, which is laid frog downwards, as in Fig. 2a, then he takes the point of his trowel and runs a gutter in the mortar along about the centre of the course of bricks. The bricks are then laid frog downward, making the frog fit over the gutter in the mortar, as shown in Fig. 2b. That this is the case has been proven by a test, in which fifty bricks were selected on different jobs; so that the fault could not be claimed as local to any one contractor, and of the fifty selected but three frogs contained any mortar, and in those cases it seemed to have been more by accident than intention. The present practice clearly destroys the bonding and shearing theory supporting the use of a frog in bricks, and it also furnishes a very strong argument against its use at all.

The above is by no means the most serious defect of a wall so constructed. Consider the effect the loss in bearing area, caused by this practice, has on the compression value of a wall. The average brick laid flat gives a bearing area of $4'' \times 8\frac{1}{2}'' = 34$ sq. ins., the area of the frog is $2'' \times 6'' = 12$ sq. ins., so that the actual bearing area of a frogged brick is 22 sq. ins. Thus the frog decreases the effective strength of the wall by 35%. Actually the strength is decreased by much more than 35%, as experiments will show. Brick masonry, under an increasing load, begins to fail by the lime failing and breaking the bond between the small particles of sand; the mortar then acts in the same manner as sand, flattening out and flowing to the points where the pressure is least, which would be in this case the outside edge or the frog of the brick. Also, the sand in flowing at the edges and at the frog, assumes the same angle of repose as ordinary sand (about 45°), and thus decreases the bearing area of the upper brick, as shown in Fig. 3. It might be pointed out, further, that the process of failure of a wall is, first, the failure of the mortar as described above, and later the failure of the bricks. Between these two failures there is a difference of anywhere from 15 to 35% of the ultimate strength of the wall. To illustrate: if a wall has an ultimate compressive strength of 1,000 lbs. per sq. in., the mortar will fail anywhere between 650 and 850 lbs. per sq. in.

That the different positions of the frog has a real effect upon the strength of the wall is recognized by our building by-laws where pier wall construction is defined as requiring that the bricks should be laid frog upwards and the wall grouted, thus making certain that the frog is well filled. Additional bearing values must therefore be allowed for a wall so constructed. If a wall of a certain compressive strength per sq. in. is desired and the bricks may be laid either of these ways, it follows that to build the wall pier construction throughout, ought to mean a saving in bricks, and thus an economy in material would be effected.

Another argument which is sometimes advanced in favor of the frog is that bricks are easier and quicker laid when placed frog downward. As has been already stated, this is the Canadian practice. English and continental practice is to lay every brick frog upward, and fill the frog. The question of which way is easier and quicker seems to be only a matter of which way a bricklayer is taught and rapidity then is but a matter of practice.

Variation in Size of Bricks.—Bricks vary in height from 2 ins. to 3 ins., due to at least two causes: (1) a difference in the size of the forming mould; (2) the process by which they are solidified. It seems necessary to establish a minimum and a maximum dimension in height, allowing a variation of not more than one-eighth of an inch in the finished product. The difficulties of estimating air-shrinking and fire-shrinking in clay brick is well known, but they are not such that they cannot be overcome. That some precaution is necessary can be very well illustrated by considering the difference in the amount of mortar in the face and back of a wall, where the bricks differ by one-eighth inch in height. (The writer knows of cases where the face and filling bricks have differed by as much as one-half inch.) The difference of one-eighth of an inch in the height of the bricks would mean a difference of one-half to the vertical foot of wall, assuming four bricks to the vertical foot. In a fifty-foot wall there is a difference of twenty-five inches in

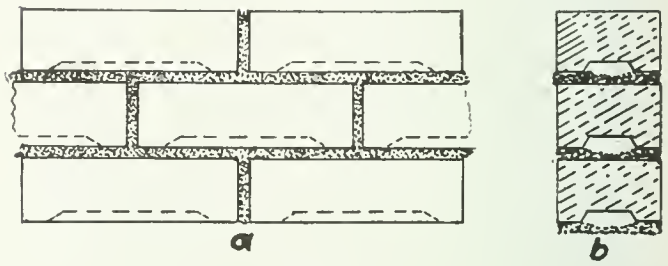

Fig. 2.

the amount of mortar. The mortar is the weaker material in the wall, and therefore the inside of the wall, which has to carry the floor loads and should be stronger, is weaker than the outside.

Classification According to Strength.—There should also be a minimum requirement of strength in a definite period after a brick is made. Bricks, as they are used now, vary in crushing strength from 400 lbs. per sq. in. to 7,000 lbs. per sq. in., and are classified according to appearance and not according to strength. The above-mentioned brick showing a strength of 400 lbs. per sq. in. would probably be used as a filler, and placed in the back of the wall where it would have to carry the greater portion of the load. It is because these poor bricks are used that building regulations are justified in allowing a compressive strength of from 50 to 75 lbs. per sq. in. This laxity in allowing the use of the poor bricks is the reason for discounting the strength shown in 85% of the bricks produced, for any of the modern kilns will show 85% of the bricks to be hard burnt. Therefore, if some rigid standard was enforced for factory and office building construction, such as a requirement of 2,000 lbs. per sq. in. in compression, one month after being made, it would only exclude about 15% of the bricks produced and many uses could be found for the rejected 15%. Building regulations would then be justified in raising the allowable unit stresses in brick wall construction.

Lime versus Cement Mortar.—In Table I. is given the results of compression tests on blocks of cement and lime mortar.

Table I.—Strength of Mortars.

Composition of mortar.	Age when tested.	Strength in lbs. per sq. in.
1 lime : 2 sand	1 month	94.
1 lime : 2 sand	3 months	136.
1 lime : 2 sand	6 months	245.
1 cement : 3 sand	2½ months	1352.
1 cement : 3 sand	8 days	655.
1 cement : 3 sand	13 days	1320.
1 cement : 3 sand	28 days	2155.
1 cement : 2 sand	8 days	895.
1 cement : 2 sand	13 days	2325.
1 cement : 2 sand	28 days	2690.

The table shows that cement mortar is much stronger and gains strength much more quickly than the lime mortar. In factory and tall building construction, both of these points of superiority of cement mortar are of importance. By the use of a mortar such as 1 part cement to 2 parts sand a much higher allowable strength could very safely be allowed than is allowed at the present time, which would mean an additional economy in material.

Another difficulty with mortar, and especially lime mortar, is the variation in quality due to carelessness in proportioning and mixing. The proportions are usually left to the experience and guessing ability of the mortar mixer, and seldom, if ever, is the material accurately measured. The only tests required of the fitness of the resulting mixtures are their spreading and working qualities, which are in many cases very different from strength qualities. More care in measuring and mixing the materials of a mortar would improve its strength and reliability.

The purpose of this article is to point out where improvements might be made. What has been termed carelessness is as much the fault of the architect and engineer as it is the fault of the brickmaker or bricklayer. If specifications were drawn up more carefully and precisely a great many of the inaccuracies in using building materials would be eliminated; for instance, if architects, by agreement, were to issue specifications for bricks without frogs it would be but a short time until the manufacturers would be making only that kind of brick. To the brickmaker the frog is more or less of a nuisance anyway, and its elimination would, in most cases, mean but slight changes in his moulding machinery. The writer knows of four firms of architects doing business in Toronto and Montreal whose specifications are of the type described. Most of the other difficulties pointed out could be gotten rid of by a similar process.

In Canada at present the ceramic industries are booming. The development has improved the quality as well as increased the quantity and ultimately the improvement in quality must be recognized by increasing the allowable safe loads and thus cutting down the waste in building operations.

The following points are suggested as improvements over the present practices:—

1. The elimination of the frog in bricks.
2. The use of cement mortars, not exceeding 1 part cement to 3 of sand, in all but residential buildings.
3. A definite minimum and maximum height for all bricks.
4. Better and more precise specifications for proportioning and mixing mortars.
5. Increased bearing values.
6. That the following be the specification for bricks, which is the specification proposed by the American Society for Testing Materials:—

Selection of Samples.—For the purpose of tests, brick should be selected by some disinterested and experienced person to represent the commercial products. All brick shall be carefully examined, and their condition noted before being subjected to any test.

Transverse Test.—At least five brick to be tested, laid flat-wise with a span of seven inches, and with the load applied at mid span. The knife edges shall be slightly curved in the direction of their length. Steel bearing plates, about ¼-inch thick and 1½-inches wide, may be placed between the knife edges and the brick. The use of a wooden base-block, slightly rounded transversely across its top, upon which to rest the lower knife edges, is recommended. The modulus of rupture shall be obtained by the following formula.

$$R = \frac{3\ W\ L}{2\ b\ d^2}$$

in which:—

L. is the distance between supports in inches.
b. is the breadth of the bricks in inches.
d. is the depth of the brick in inches.
W. is the load in pounds at which the brick failed.

The half brick resulting from the transverse test shall be used for the compression and absorption tests. One half to be crushed in its dry condition. The other half to be used for the absorption test and crushed while in this wet condition. No specimen shall be used if any part of the line of fracture is more than one inch from the centre line.

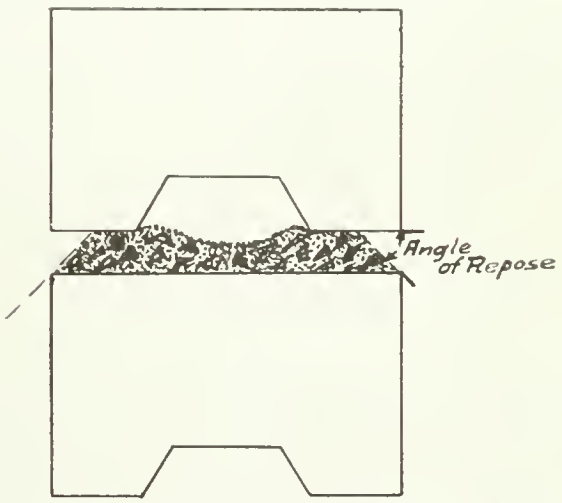

Fig. 3.—Showing Effect of Crushing on the Mortar.

Compression Test.—Compression test shall be made on half brick, resulting from the transverse test. The brick shall be bedded flat-wise on blotting paper, heavy fibrous building paper, or heavy felt, to secure a uniform bearing in the testing machine. In case the brick have uneven bearing surfaces, they shall be bedded in a thin coat of plaster of Paris. For dry test, before applying the plaster of Paris, the bearing surfaces of the brick shall receive a coat of shellac. The machine used for compression tests shall be equipped with spherical bearing block. The breaking load shall be divided by the area in compression, and the results reported in pounds per square inch.

Absorption Test.—At least five half brick shall be first thoroughly dried to constant weight, at a temperature of from 200 to 250 degrees F., weighed, then placed on their face in

water to a depth of one inch, in a covered container. The brick shall be weighed at the following intervals: one-half hour, six hours, and forty-eight hours. Superfluous moisture to be removed before each weighing. The absorption shall be expressed in terms of the dry weight and the balance used must be accurate to five drams.

Freezing and Thawing Test.—In case the freezing and thawing test is desired, at least five bricks shall be thoroughly saturated by immersion in cold water, the temperature of the water to be raised to 200 degrees F. in thirty minutes, then allowed to cool. The specimen shall be immersed in ice water for not less than one hour, weighed, then transferred to the refrigerator and supported in such a manner that all faces will be exposed. The specimen shall be subjected to a temperature of less than 15 degrees F. for at least five hours; then removed and placed in water at a temperature of not less than 150 degrees F., nor more than 200 degrees F., for two hours. This operation shall be repeated twenty times, after which the bricks shall be again weighed, still saturated The character of the bricks shall be noted before and during the test, and all visible changes noted. Immediately on completion of this test, samples are to be thoroughly dried and subjected to the transverse and compression tests.

Requirements.—The following requirements shall be met:—

Modulus of rupture shall be as follows:—

	Average.	Minimum
For samples thoroughly dry	400 lbs.	325 lbs
For samples thoroughly saturated .	275 lbs.	225 lbs
For samples subjected to freezing and thawing process	275 lbs.	225 lbs.

The ultimate compression strength shall be as follows:—

	Average. lbs. Sq. In.	Minimum lbs. Sq. In.
For samples thoroughly dry	3,000	2,500
For samples thoroughly saturated ..	2,500	2,000
For samples subjected to freezing and thawing process	2,500	2,000

The absorption shall not average higher than 15 per cent., and in no case shall it exceed 20 per cent.

The freezing and thawing tests shall not cause cracking or serious spalling in any of the bricks tested, nor cause the serious disintegration of the material.

Economic Minerals and Mining Industries of Canada, a 77-page illustrated pamphlet, by Mr. J. McLeish, Chief of the Division of Mineral Resources and Statistics, contains data concerning the main geographic and geologic features of the country, and a brief description of the same, treating separately each mineral and mineral product. A summary of the mineral production of each province and references to the laws governing mining and the ownership of mining lands in the various provinces, also are included. The pamphlet is issued by the Mines Branch, Department of Mines, Ottawa.

The railway-terminal problem of Chicago is to be investigated under the direction of a public commission composed of leading engineers and business men. This is to be undertaken for the reason that the council committee on railway terminals, which was forced by public agitation to order such an investigation made under its direction, is considered to be prejudiced in favor of the plans submitted by the Pennsylvania Railroad. The committee has openly advocated these plans, and has predicted that they will be approved by the city authorities, thus indicating that it will give slight consideration to other plans or to the general problem of improvement of the railway-terminal system of the city.

ROYAL COMMISSION'S SEWAGE DISPOSAL ENQUIRY.

THE Royal Commission on Sewage Disposal (Great Britain) has recently issued an appendix to its eighth report which was published last autumn. This report dealt with the establishment of some co-relation between the chemical character of the water of rivers and streams, and the relative purity and freedom of them from nuisance. It will be remembered that the Commission expressed its opinion that the liability of a stream to become objectionable under unfavorable conditions might fairly be estimated by the amount of dissolved oxygen absorbed in five days at a constant temperature of 65° F. This it regarded as the best indication of the liability of a stream to become offensive in warm weather and that is surpassed in value as an index to the stream's conditions, the percentage of ammoniacal nitrogen present.

The Commission's conclusions defined the limits of temperature variations as 37.2° F. lowest, and 64.4° F. highest, from observations taken on a number of streams.

In the appendix, now issued, the Commission sets forth in detail the experimental work which constituted the basis of its recommendations and a great deal is contained therein of value to engineers concerned in the prevention and abatement of river pollution. "Engineering" (London), outlines the work as follows:—

In commencing their operations the Commission addressed inquiries to all the county medical officers of England and Wales, as well as to the various river conservancy boards, and from the information thus acquired, a preliminary list of fifty streams was drawn up and personally inspected. As the result of this examination, which was carried out by Mr. G. B. Kershaw, the engineer to the Commission, twenty-five places were selected for further inspection and examination, but in the end attention was mainly concentrated on sixteen of the sites thus chosen. The object of the inquiry being to correlate the chemical characteristics of the waters of a stream with its state as estimated by the eye and nose, careful note was taken of the condition of its bed and banks. Stones from the shallows were examined for algæ growth, water insects, and the like, and special attention was paid to any deposits of mud in the pools and banks. Fish life was also carefully noted, and at the same time data were taken of the relative rapidity of the streams, which were classified as follows:—

Mean current velocity.	Character of stream.
From 20 ft. per minute downwards	Sluggish to very sluggish
From 20 ft. to 40 ft. per minute	Slow
" 40 ft. to 60 ft. "	Moderate
" 60 ft. to 80 ft. "	Rapid
Over 100 ft. per minute	Very rapid

Based on these observations the Commission have been able to tabulate the features given in the accompanying table as characteristic of the relative purity of natural waterways in normal summer conditions.

The cases of pollution inquired into by the Commission covered every condition, from insignificant to distinctly bad. The relative volume of effluent to the stream in which it was discharged was in some instances as low as 1 to 2, and in others less than 1 to 1,000, but in all cases a pretty close connection was established between the results of the oxygen-absorption test and the place which would be assigned to the stream in the table, as

the result of an inspection by eye and nose. The grev growth mentioned in the last column of the table appears to be eminently characteristic of an undesirable degree of pollution.

The efficacy of the test recommended depends upon the fact that clean river water in normal condition, and at 60 deg. F., contains in solution 7 c.c. of oxygen, or 1 part by weight, in 100,000 of water. If polluted, this dissolved oxygen, as the result of bacterial action, enters into combination with the organic matter present, with a consequent reduction in the amount of that freely dissolved, and this loss of oxygen thus serves to indicate the degree of pollution of a stream. All river water contains some organic impurity, and hence, if kept in conditions in which the store of oxygen cannot readily be replaced from the air, there will, on keeping, be always some reduction in the quantity of oxygen contained in solution. With clean river water, however, this loss is small, whilst with badly contaminated streams the whole of the dissolved gas may disappear from the sample under test. The connection between the oxygen dissolved and the character of the stream is stated to be as follows:—

	Gramme of dissolved oxygen in 5 days.
Very clean	0.1
Clean	0.2
Fairly clean	0.3
Doubtful	0.5
Bad	1.0

The figures refer to the weight lost from 100,000 grammes of the water under test. It will be noted in the above table that the figure given for a badly polluted stream exceeds the total amount of oxygen which water is capable of holding in solution at a temperature of 65° F. This, in fact, was frequently the case in the tests, which were made by mixing the sample under observation with tap water in such proportion that some 50 to 60 per cent. of the total dissolved oxygen was taken up in the five days over which the test extended. This degree of dilution was found by experiment to yield the most concordant results.

A very fair correlation was, as already mentioned, also established between the condition of a stream and the ammoniacal nitrogen present, but the Commissioners came to the conclusion that this test was on the whole the less satisfactory of the two, since the ammonia figure in the case of a stream receiving sewage effluents was not always as good an index of the actual condition of the stream as the dissolved oxygen test was found to be.

A most interesting feature of the present series of researches has been the comparisons made between the condition of a stream above a sewage outlet and below it. Probably the most interesting observations made in the whole investigation are those on the River Avon, from Rugby to Stratford. This river rises in Northamptonshire, near Naseby, and flows across Warwickshire to the River Severn at Tewkesbury. It is a winding, sluggish stream, with a muddy bed, and there are many weirs on it. On it, or its tributaries, are situated the towns of Rugby, Coventry, Kenilworth, Leamington, Warwick, Stratford, and Evesham, the distance between successive centres of pollution being generally about 10 miles. For many years the stream received the untreated sewage effluents from all the centres above named; but as matters stand to-day, it would appear that the effluents sent into the stream are in the main fairly satisfactory, and that the river is maintained in a passable condition. Between Rugby and Stratford the proportion of sewage-derived water in the river never falls below 1 in 8 or 1 in 9, and in one reach amounts to as much as 1 in 2.5.

The town of Rugby has a population of 21,000, and is sewered on the "partially separate" system. The sewage, which is "domestic" in character, is treated in septic tanks, the effluent from which is passed through percolating filters and irrigated over land. This effluent is stated to be bright and clear, with a clean, healthy smell, and is

Features Characteristic of Streams in Normal Summer Weather.

Condition of water as regards	"Very Clean"	"Clean"	"Fairly Clean"	"Moderate"	"Doubtful"	"Bad"
Suspended matter	Clear	Clear	Fairly clear	Fairly clear	Slightly turbid	Turbid
Opalescence	Bright	Bright	Slightly opalescent	Distinctly opalescent	Opalescent	Opalescent
Smell on being shaken in bottle	Odorless	Faint earthy smell	Pronounced earthy smell	Earthy wormy smell	Strong earthy wormy smell	Soapy, fœcal, or putrid smell
Appearance in bulk	Limpid	—	Slightly brown and opalescent	Brown and opalescent	Black looking	Brown or black and soapy looking
Delicate fish	May be plentiful	Scarce	Probably absent	Absent	Absent	Absent
Coarse fish	—	Plentiful	Plentiful	Present	Scarce	Do
Stones in shallows	Clean and bare	Clean	Lightly coated with brown fluffy deposit	Coated with brown or dark green layer	Coated with brown fluffy deposit	Coated with grey growth and deposit
Stones in pools	Do	Covered with fine light brown deposit	Do	Coated with brown deposit	Do	Coated with brown or black mud
Water weeds	Scarce	Plentiful; fronds clean except in late autumn	Plentiful; fronds brown-colored in places	Abundant and covered with deposit in pools	Plentiful and covered with fluffy deposit	Scarce
Green algæ	Do	Moderate quantities in shallows	Plentiful in shallows	Plentiful	Abundant	Abundant in protected pools
Grey algæ	—	—	—	—	Present	Plentiful
Insects, larvæ, etc.	—	—	—	Plentiful in green algæ	Plentiful in green algæ	Abundant in green algæ

non-putrescible on incubation. It contained in 100,000 parts about 1.5 parts of matter in suspension, and when maintained at 65° F. for five days took up 1.97 parts of oxygen per 100,000.

The ratio of the sewage effluent to the dry-weather flow of the river is about 1 to 8; the river flow being 4,500,000 gallons per twenty-four hours. No smell was observed near the Rugby outfall, and there was very little of the grey growth, which, as already stated, seems to be characteristic of polluted waters. Small coarse fish were present in the water below the outfalls, although in dry weather the admixture of the effluent caused considerable deoxygenation of the water in the sluggish reaches. The Coventry sewage reaches the river 13 to 14 miles further down. At this point the river has practically completely recovered from the effects of the Rugby discharge, at least so far as its chemical constitution is concerned, the chlorine content of the water alone being permanently increased. Coventry has a population of 90,000, and the sewage discharged amounted to 4,000,000 gallons per day in 1911. It is of a domestic character, but with trade wastes. The treatment to which it is subjected before discharge is settlement followed by land irrigation and land filtration; the area assigned for this purpose was 378 acres at the time of the observations, but has since been largely augmented. The effluents are stated to be very variable in quality. The dry-weather flow of the river, which is said to be fairly clean on its arrival at Coventry, is put at 7,500,000 gallons per hour, and the ratio of dilution less than 3 to 1. Under these conditions of an inferior effluent and little dilution there was an abundant grey growth below both outfalls, and masses of putrifying mud have formed in parts of a very sluggish reach, where many dead fish are found in warm, dry weather, accompanied by an objectionable smell. Nevertheless, the river purifies itself further on, and though it receives also the sewage effluent from Leamington, Warwick, Kenilworth, Stratford, and Evesham, it is, as already stated, now maintained in a passably fair condition, so far as actual nuisance is concerned. Bacteriologically the results are much less satisfactory, although there is in all cases a well-marked progressive improvement of the river as the distance from each new outfall increases. It appears, however, that from the standpoint of bacteriology reversion to the original state of the unpolluted stream cannot in general be effected within the limits of distance which are probable in this country between independent sources of pollution.

The observations made at Berkhampstead have rather a special interest, since the sewage is discharged not into a natural stream, but into the Grand Junction Canal, where practically the whole of the flow is merely that due to lockage operations. The sewage is from a population of 8,000, and is "domestic" in character. It is treated in closed septic tanks, followed by double-contact beds, the average flow being 500,000 gallons per 24 hours. The effluent is slightly opalescent, with a brown tint, and generally, but not always, has a clean smell. Two out of seven samples putrified on incubation. This effluent is discharged into a pound, where the water is practically stagnant. This water has a stale wormy smell on shaking, but there was no smell on the tow-path. Much grey fungus was present below the outfall, and the only fish observed in the pound were minnows. Several cases in which sewage is discharged direct into the stream without treatment of any kind are discussed in the report. Apparently where the dilution is sufficient this practice does not give rise to any active nuisance, but even in these cases the discharge of paper, corks, and matches into the stream is objectionable, and could be avoided by straining the sewage before discharge.

"DUKE OF CONNAUGHT" TOLLS.

The Canadian Gazette publishes the tariff of tolls submitted by the Canadian Vickers, Limited, in connection with their floating dock, the "Duke of Connaught," at Montreal. The schedule has been recommended for approval, subject to amendment, by the Minister of Public Works. It is as follows:—

Montreal Floating Ship-Dock Canadian Vickers, Limited Tariff.

Gross Reg. Tons.	1st day	Commencing 24 hrs. after vessel is raised. Following days or fractions thereof each.
Up to 1,000.....	$ 300.00	$ 80.00
1,000— 1,199.....	340.00	95.00
1,200— 1,399.....	365.00	95.00
1,400— 1,599.....	390.00	95.00
1,600— 1,799.....	415.00	110.00
1,800— 1,999.....	450.00	110.00
2,000— 2,249.....	475.00	110.00
2,250— 2,499.....	500.00	125.00

23,000—23,999.....	2,650.00	1,150.00
24,000—25,000.....	2,750.00	1,250.00

THE MONTANA IRRIGATION PROJECT.

The Sun River diversion dam, a part of an immense irrigation project in Montana, is at present under construction by the United States Government. A contract has just been awarded to MacArthur Bros. Company, of New York, consisting of the construction of about forty-five miles of main canal and several small tunnels, aggregating about three-quarters of a mile in length. The canal will have a capacity of 1,700 feet per acre per day. It will be twenty-seven feet wide at the bottom and sixty-nine feet in width at the top, the water having a depth of eleven feet. Its cost will amount to about $900,000.

THE SASKATOON TRAFFIC BRIDGE

THE new traffic bridge which will supplant the present steel bridge at Saskatoon, is in its early stages of construction, and will probably be ready for use by December of next year. The present bridge was built in 1906-07, but during the past six years the city has grown so rapidly that the structure is quite inadequate to accommodate the large traffic crossing the river. The old bridge is built on concrete piers. It is interesting to note that the petition of 1904, asking for a bridge at Saskatoon, estimated the population at 1,200, while the 1901 census had placed it at 113, a conservative estimation of the present population being 20,000.

Early in 1912 the need of a new and larger bridge was voiced, resulting in a thorough investigation on the part of the Board of Highway Commissioners, and in June of last year the site was selected. It was definitely decided that the bridge should span the river between Twenty-fifth Street on the west and Saskatchewan Street, which bounds the University grounds, on the east. It was agreed that only a very wide bridge would meet the requirements.

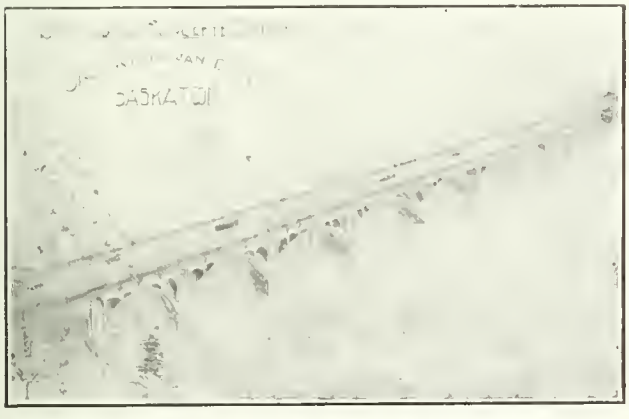

Fig. 1.—Accepted Design for Saskatoon Traffic Bridge.

The site chosen offered various difficulties from an engineering standpoint. The elevation of the bank at the University side is some fifty feet higher than on the city side. The river is about 1,100 feet wide during high water at this point. The bridge was to cross from a park on the city side to the University grounds on the other, and the aesthetic treatment demanded great care.

The Board of Highway Commissioners designed bridges of two types for this crossing—a steel superstructure on concrete piers, and a bridge composed of a series of reinforced concrete arches. The estimated cost of the two types varied by only about $6,000, and the selection became a question of type rather than cost. The steel bridge required a long approach on the city side of the river in order to overcome the grade as it was not considered practicable to build a large steel structure with so large a grade. This approach was at the best an unsightly structure, and would have caused considerable claims for property damage from residents of Twenty-fifth Street.

The reinforced concrete bridge was chosen because of greater permanency and better appearance, and as best suiting the requirements. An agreement was drawn up with the city of Saskatoon by which they agreed to pay one-third of the cost of the structure. Plans were prepared of a bridge consisting of a series of arches with a floor on a grade of 2.88 per cent. The total width of the bridge is to be 65 feet, and two 8-foot sidewalks are to be cantilevered from the roadway. Provision was made for two street car tracks, and two 14-foot roadways.

The total length of the bridge and the retaining walls at its approaches is about 1,490 feet. It consists of one arch of 25 feet span, one arch of 60 feet span, one arch of 92 feet span, one arch of 103 feet span, one arch of 136 feet span, four arches of 150 feet span, and one irregular arch of 94 feet span. The arches of 150 feet are notable as being longer in span than any in Canada.

The design was most carefully worked out and the allowable stresses are most moderate. The bridge is designed for a temperature range of from 50 degrees below zero to 90 degrees above. This variation of temperature is thought to be larger than that used in designing any other concrete bridge.

Tenders were called for the construction of the bridge and closed on July 15. The R. J. Lecky Company, of Regina, was the lowest bidder and its tender was accepted. The price for the estimated quantities was some $240,000. Cement and reinforcing steel are to be supplied by the Board, and the estimated quantities are 725 tons of reinforcing steel and 114,000 bags of cement. The cost of these must be added to the contract price to obtain the actual cost of the work.

The bridge was designed under the personal direction of Mr. A. J. McPherson, chairman of the Board of Highway Commissioners, by the engineering staff of the bridge branch, of which Mr. A. P. Linton is assistant chief engineer. Mr. Daniel B. Luten, of Indianapolis, who is an authority on concrete bridges, acted in an advisory capacity, and examined and approved the general arrangement and the working plans.

In Western Canada the bridge will only be surpassed in size and importance by the bridge over the North Saskatchewan at Battleford. It will, however, be by far the largest reinforced concrete bridge in this country, and will take high rank among the big bridges of the North American continent. The illustration gives an idea of the accepted design, a more detailed description of which will be published at a later date.

According to the report of Mr. J. McLeish on Economic Minerals and Mining Industries in Canada, these statistics are given for the total production of petroleum in the Province of New Brunswick; in 1911, an aggregate of 2,461 lbs., valued at $3,019; and in 1912, 2,679 lbs., valued at $3,799.

Railway building in Western Canada is one of the wonders of the age, over seven miles of new track being laid down for every day in the year. Each year the railway map of Western Canada shows hundreds of miles of extensions laid in all directions. The railway mileage of the Western Provinces in 1900 was 3,680, and is now 13,560 miles, and before long, instead of one, three transcontinental railroads will belt the prairies, with branches and feeders extending in every direction, opening up large areas of new territory for agricultural and commercial development. The railway extension programme laid down for completion this year by the Canadian Pacific, Canadian Northern and Grand Trunk Pacific Railways is the largest yet attempted. Active work is now in progress on the Hudson's Bay Railway, which, in addition to forming a new outlet and more direct ocean communication for the Western Provinces, will open up a large area of new and undeveloped territory to the north. This extensive increase in transportation facilities will, without doubt, increase the acreage cultivated, which will in turn, create an ever-increasing demand for manufactured goods.

MASSACHUSETTS HIGHWAY COMMISSION REPORT, 1912.

THE Massachusetts Highway Commission has under its charge road work, motor vehicles and the supervision of telephone and telegraph companies, each with its own practically separate department. The commissioners are Col. Wm. D. Sohier, chairman; Mr. F. D. Kemp, and Mr. Jas. W. Synan. The highway department has charge of all road and bridge work, advice to municipal authorities, etc. At its head is the chief engineer, Mr. A. W. Dean, whose assistant is Mr. S. A. Parsons. The office engineering department which makes the surveys, prepares all plans and estimates, etc., is in charge of Mr. A. M. Lovis, and under him are employed 20 to 50 engineers, draftsmen, instrumentmen and rodmen, depending on the season of the year and the amount of work on hand.

The State is divided into four divisions, each in charge of a division engineer, who has one or two assistants in charge of particular work, like "small town" work, maintenance, etc., and as many resident engineers are assigned to his division from time to time as are necessary to supervise and inspect the actual work which is in progress. Most of the principal engineers and assistants have been in the service for over 10 years, and quite a number for a much longer period. The various departments report to the commission through its secretary.

During the year ending November 30th, 1912, the commission completed 11.25 miles on contracts that were pending at the beginning of the year and 21.57 miles of roads commenced during the year, making a total of 32.82 miles of construction for the year, or a grand total of 920.51 miles since work began. Construction was commenced, but not completed, on 20.16 miles of road in 1912.

Of the above 32.82 miles, 4.58 miles were of water-bound macadam; 6.72, gravel; 3.19, sand-bound with oil; 12.02, bituminous macadam; 3.93, water-bound macadam with an oil surface applied; 2.24, gravel with the top service bound with bituminous binder. The costs of construction of these highways are shown in the accompanying Table I., in such a manner that comparisons may be made between the different costs of work in different portions of the State under varying conditions.

In Massachusetts, as elsewhere, the increase in travel by automobiles, and the use of motor trucks for long distances to and from cities, has augmented the question of maintenance into one of vital importance. The report of the commission, from which this information is derived, states that in 1912 over $500,000 was spent in maintaining state highways, $200,000 of which was provided by direct appropriation by the Legislature and the balance secured from motor vehicle fees. (The total expenditure by the commission up to the end of last year for the construction of state highways since the work began, amounted to $8,379,080.) Bituminous material was used in maintenance work during 1912, on 283.55 miles, and in construction on 21.38 miles, there existing at that time 729.83 miles of state highway on which bituminous material was used either in construction or maintenance. In his report, Mr. A. W. Dean, chief engineer, states: "While there have been a few failures of bituminous roads, the use of bituminous material seems at the present time to be an economical way of preserving the roads under the present traffic, and I recommend continuing the use of this material in construction and maintenance."

The commission is of the opinion that it is absolutely necessary to-day to apply some form of dust layer or bituminous binder to macadam roads, either by a surface application or by incorporating it into the upper 3 in. of broken stone. If this is not done the roads will shortly be destroyed by the high-speed motor vehicle travel. The commission states that it has found the application of bituminous binders under pressure produces more uniform results than were formerly secured by the so-called gravity method. The cost of maintaining the roads is over $500 per mile per year and will probably be more in the future, certainly until many miles of the older roads on through

TABLE I—APPROXIMATE COSTS OF ROADS COMPLETED IN 1912

Town	Type of Surface	Length of calculations		Drainage, culverts and bridges total cost	Grading and foundation cost per mile	Cost of surface	
		Miles	Sq. yds.			Per mile	Per sq yd.
Amesbury	Macadam, 4½-in., trap rock, bituminous binder	.28	2,464	$ 907	$3.564	$7,593	$0.86
Ashby	Macadam, 5-in., local stone	.60	5,280	592	3,133	5,275	.60
Ashby, 1911	Macadam, 5-in., local stone	.44	3,872	296	4,600	4,968	.56
Bourne	Macadam, 3¾-in., trap rock bituminous binder	.68	5,984	624	1,348	7,135	.81
Chelmsford, 1911	Gravel, 5-in.	1.42	12,496	672	2,447	1,201	.13
Dighton, 1911	Macadam, 4¼-in., local stone, bituminous surface coat	1.02	8,976	141	1,140	3,727	.42
Erving	Concrete, 5-in., bituminous surface coat, concrete beam bridge	.03	264	2,299	4,977	10,833	1.25
Franklin, 1911	Gravel, 6-in.	1.17	10,296	467	2,915	1,795	.20
Haverhill	Macadam, 5 in., trap rock, bituminous binder	.43	3,784	1,140	3,602	7,116	.80
Lakeville	Macadam, 4¼-in., local stone, bituminous binder	1.24	10,912	282	2,890	5,690	.64
Lanesborough	Macadam, 4-in., trap rock, bituminous binder	.34	2,992	400	5,490	5,976	.66
Montague, 1910	Macadam, 5-in., local stone	.82	7,216	253	2,058	4,416	.50
Plymouth, 1911	Sand and oil, 3½-in., mixed	1.00	8,800	859	8,192	4,027	.45
Raynham	Macadam, 4-in., local stone, bituminous binder	.96	8,448	326	3,731	6,262	.74
Salisbury, 1911	Macadam, 4¼-in., local stone, bituminous binder	1.22	10,736	621	2,160	5,225	.59
Sandwich	Sand and oil, 3-in., mixed	.85	7,978	318	1,245	4,545	.48
South Hadley	Macadam, 5-in., trap rock	1.31	11,528	1,131	5,754	4,575	.52
Spencer, 1911	Macadam, 5 in., trap rock, concrete arch	.03	264	4,727	10,166	9,441	1.07
Swansea, 1911	Macadam, 4-in., local stone	.78	6,864	543	1,356	2,946	.43
Tyngsborough	Macadam, 4-in., trap rock, bituminous binder	.72	6,336	1,581	1,525	6,740	.76

routes, especially near the cities and larger towns, where the traffic is extremely heavy, have been reconstructed with some more permanent surface.

In a subsequent issue the part of the commission's report dealing with the traffic census will be summarized.

CONCRETE ROADS IN WAYNE COUNTY, MICH.

WAYNE County, Michigan, in which Detroit is situated, is credited with having the finest system of concrete roadways in the world. They are over 100 miles in length. The upkeep expense is less than $5 per mile per year, which includes the cleaning of ditches and the cutting of weeds along the roadside; and they are always smooth and dustless.

Practically every government report that has been issued during the past five years has told of the failure of the ordinary macadam road to withstand the traffic of the present day. In New York State the maintenance expense has gone as high as $1,000 per mile per year. And within a few years these highways have had to be completely rebuilt. The concrete highway, which originally costs a third more, is practically permanent. But several conditions govern the building of concrete roads which must be observed. In the first place they must be placed honestly as to the proportion of gravel, sand and cement; they must be "cured," that is, watered and allowed to stand for several weeks before being used; and they must be built under good weather conditions. When these features are complied with the concrete highway will generally last for many years without being touched.

"The Story of a Country Road" is the title of a booklet that Edward N. Hines, road commissioner of Wayne County, is distributing, and which explains clearly how the concrete road is made.

"We prepare and shape the subgrade, roll it hard with a 10-ton roller and lay the concrete right on the natural sub-soil," writes Mr. Hines. "Side rails are used and when the concrete has become sufficiently hard to remove the rail the finishers pare off the outer edges to prevent a sharp dividing line between the concrete and the gravel shoulders.

"Our trunk roads are built 16 feet wide with gravel shoulders four feet wide on each side. The lesser-travelled roads have 12 and 15 feet of concrete with a minimum width over-all of 24 feet. We have also built concrete roads from 10 to 18 feet wide. They are always wide enough to make passing of teams or automobiles going in the opposite or the same direction very easy.

"The concrete is put down wet so that no tamping is necessary after it is placed. When this is done no workman is permitted in anyway to disturb the concrete by stepping in it or throwing anything on it. Smoothing is done with simple wooden floats.

"Each day's work is finished up to an expansion joint and no more than 20 minutes is permitted to elapse between batches of concrete during the day. The work of the day is covered with canvass and the next day the canvass is removed and the concrete covered to a depth of about two inches with any sand or loose soil available to keep the concrete from drying too rapidly. The concrete is sprinkled continuously for eight days. Roads are not opened for traffic until at least two weeks after the last concrete is put in place.

"Machinery is used whenever the same or a better result can be secured and large hauling engines trail from two to four wagons each loaded with stone or gravel. Graders are also drawn by steam, doing the work of from 6 to 8 horses more efficiently and rapidly. Old roads are rooted up with a scarifier or plow. Water is pumped in pipes for miles by gasoline engines. Stone and sand on some of the roads is unloaded with a grab bucket and many smaller and economical labor-saving devices are employed. Cement is mixed in a mechanical batch mixer.

"The cost of the roads averages from $12,000 to $16,000 per mile, as Wayne County has to have all materials shipped in. It would be higher if it were not for our labor-saving devices. When far from the city the men are boarded and given cots in tented cities. We have nearly 1,100 employees, and politics cut no figure in the employment of them."

A NOTABLE PONTOON BRIDGE.

A wooden pontoon bridge to temporarily cross the Panama Canal at Paraiso, is briefly described in the Canal Record. The plans are based upon designs obtained from the Chicago, Milwaukee and St. Paul Railway, which has used pontoon bridges of this type for many years. One of the most notable of its bridges is that over the Mississippi River at Prairie du Chien, Wis., which has been in service 35 or 40 years. In the construction of the Canal pontoon bridge, a somewhat simpler design will be followed, consisting of a timber scow 55 feet wide, 378 feet long, and six feet deep. On top of this hull, a wooden trestle, following quite closely the ordinary type of construction, will be built to an elevation of about 113.5 feet, and on this will be placed a railroad track and a highway for vehicles. The spans will be 14 feet between centres, and at these points, a transverse wooden truss, with iron rods, will be placed in the hull to carry the concentrated loads. Lighter trusses, without rods, will be placed at 2-foot intervals between the heavier trusses. The sheathing on the hull will be four inches thick at the bottom and sides, and three inches on top. To minimize the bending and shearing stresses to which the structure will be subjected, the design includes two heavy stiffening trusses, the stringers under the rails being utilized as top chords, while the lower chords are placed at the bottom of the hull. In addition, there will be heavy longitudinal keelsons.

The bridge is designed for a train load of 4,000 pounds per running foot. In order to reduce the expense of the approaches as much as possible, it is proposed to use as a connection between the bridge and the shore some of the spare lock gate girders, supported on rockers. These rocking approaches will have a downward grade when the water is at a low level, and an upward grade when it is at a high level. The pontoon will turn about a fixed pivot, and to avoid its projecting into the fairway of the canal, a recess will be excavated in the east bank, so that when the bridge is opened, it will leave the canal channel unobstructed. About 600,000 feet B.M. of yellow pine, or fir, timber, and 375,000 pounds of steel and iron, will be required.

Mr. Harry Croswell, surveyor and prospector, after a visit to the Sibola Creek goldfields, B.C., gave it as his opinion that immense wealth in gold, copper, lead, iron and zinc lies buried in British Columbia awaiting the opening up of railways and other means of transportation to make it possible for prospectors and miners to penetrate to the heart of the province. At present owing to natural obstructions, it is impossible to reach the wild districts where these minerals undoubtedly abound.

DESIGN OF FOOTINGS IN REINFORCED CONCRETE.

By A. N. Worthington,
Trussed Concrete Steel Company, of Canada, Limited.

THE design of footings in a reinforced concrete building presents perhaps more unusual features and difficulties than does any other portion of the building. This is due to a great extent to the fact that very little satisfactory information may be obtained on the subject from texts.

The first step, of course, is the calculation of the column loads. Great care must be exercised in this particular, as unequal pressure on the soil from two adjacent columns will, in all probability, result in cracking of the beams and slabs.

Consider a building, say, five stories high. The load which will come on the wall column footing is usually about 70% dead load which is always present, and about 30% live load which is seldom all present; while the load on an interior column footing is about 40% dead load and 60% live load. From this it is readily seen that unless the above facts have been considered in the design, the load under average conditions is less per square foot on the interior footings than on the exterior footings.

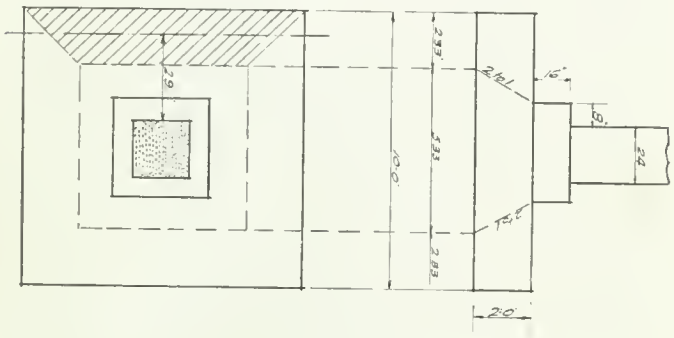

Fig. 1.

The practice of reducing the live load figured on the footing of a building over a certain height eliminates the above to some extent, though it would appear more logical to allow a greater live load reduction on the interior footings than on the exterior footings.

The principle underlying the design of a simple footing is that the portion inside the dotted lines which are at a 30-inch slope from the edge of the cap, in Fig. 1, are considered as self-supporting, and the portions outside these lines, i.e., the shaded portions in plan, are to be carried as cantilevers.

An example of the above is as follows:—

Allowable soil pressure = 4,000 lbs.; load on column = 400,000 lbs.; size of column = 24" x 24"; size of cap = 3' 4" x 3' 4" x 16".

Required area of footing $= \frac{\text{load}}{\text{soil pressure}} = \frac{400{,}000}{4{,}000} =$ 100 sq. ft. = 10' 0" x 10' 0".

Total soil reaction represented by shaded portion: $(2.33 \times 2.33) + (2.33 \times 2.17) \times 4{,}000 = 17.5 \times 4{,}000$.

Since this reaction is to be distributed over 5.17 ft., the reaction per ft. width $= \frac{17.5 \times 4{,}000 \text{ lbs.}}{5.17}$. Then area of steel required $= \frac{17.5 \times 4{,}000}{5.17} \times \frac{2.91 \times 12}{.86 \times 16{,}000 \times 22}$ = 1.54 sq. ins.

In the case where the edge of a building extends to the lot line, and it is not permissible to encroach on the neighboring property, it is seen that the load on the footings would be of an eccentric nature which would cause the footing to have an overturning tendency and throw tension into the outer face of the column. This may be

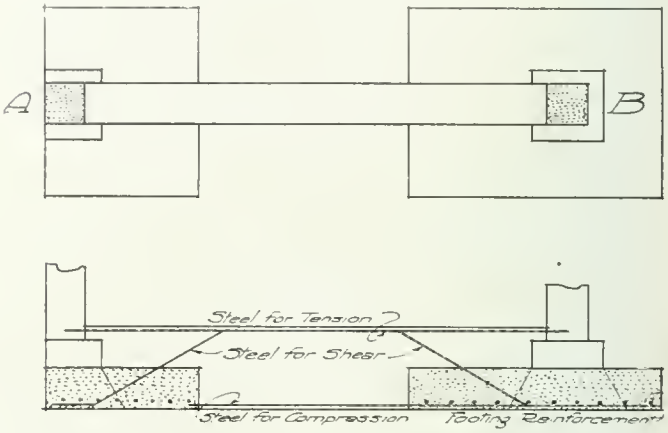

Fig. 2.

overcome by tying the wall column footing to an interior column footing by means of a wide concrete beam. Another method of accomplishing this, of course, would be to employ a raft footing spanning the entire length of the building along the walls. The former, however, is, under average loads, better engineering practice and more economical, and the writer will endeavor to illustrate briefly the designing of a footing by this method.

In the plan and section shown in Fig. 2, as previously assumed in simple footings, the portions inside the dotted lines are self-sustaining and the remaining portions are carried as cantilevers. The load which the beam will sustain will be the sum of the areas of these cantilevered portions and the area of the beams multiplied by the allowable soil pressure.

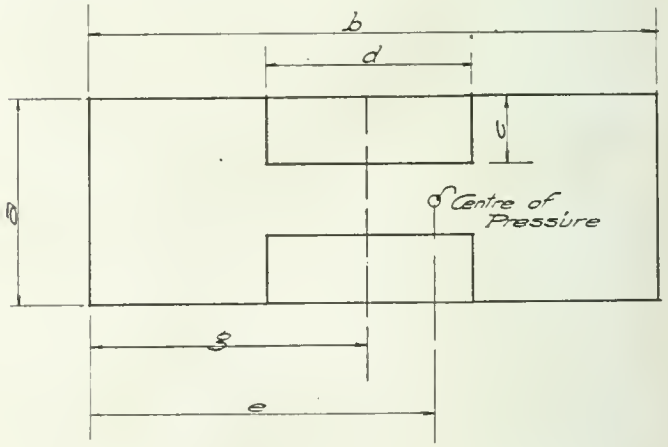

Fig. 3.

The most important adjustment to be made in the design is to have the centre of pressure of the column loads passing through the centre of gravity of the areas supporting them. If these areas do not coincide, the soil will settle on the side which is most heavily loaded, which condition may result in cracking the beams and slabs in the floors above, if not in failure.

A complete design of a footing of this type would be as follows: Let us consider a building in which the columns are spaced 24′ 0″, centre to centre. The load on the wall column "A" is 267,500 lbs., and on the interior column "B" is 504,000 lbs. Distance of centre of pressure from line x-x (Fig. 2)

$$= \frac{\text{moment of loads about x-x}}{\text{sum of loads}} = \frac{(504{,}000 \times 24) + (267{,}500 \times 0)}{771{,}500} = 15.679 \text{ ft.}$$

To distribute the area so that the centre of gravity of the area corresponds with the centre of pressure of loads, we will assume a rectangle, a b, with two pieces, c d, deducted from it in such a way that the above condition holds.

Let area required to resist load at given soil pressure = P sq. ft.

Therefore $P = a\,b - 2\,c\,d$

$$C = \frac{P + a\,b}{2\,d}$$

Moment of whole rectangle (Fig. 3) $= \frac{a\,b^2}{2}$

Moment of portion to be deducted $= 2\,c\,d\,y$

Moment of adjusted portion $= (a\,b - 2\,c\,d) \times e$

Therefore $(a\,b - 2\,c\,d) \times e = \frac{a\,b^2}{2} - 2\,c\,d\,y$

$$Y = \frac{\frac{a\,b^2}{2} - (a\,b - 2\,c\,d) \times e}{2\,c\,d}$$

By using these formulæ we would proceed as follows:

Total load = 711,500 lbs.

Area required to resist this load with allowable soil pressure of 4,000 lbs. = 192.875 sq. ft.

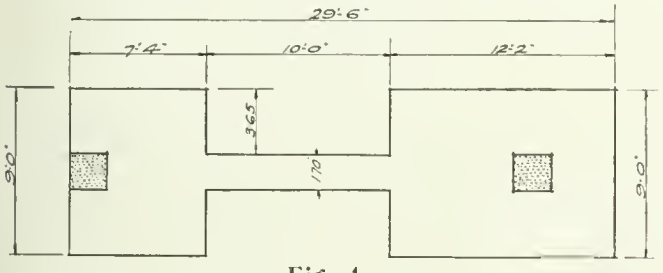

Fig. 4.

Assuming size of original rectangle as 9′ 0″ x 29′ 6″,

$$C = \frac{29.5 \times 9 - 192.875}{2 \times 10} = 2.65$$

Therefore, size of pieces to be deducted = 10′ 0″ x 3.65 ft.

Solving for $Y = 9 \times \frac{29.5}{2} \times 29.5 - (9 \times 2.95 \times \frac{2.95}{2}) \div (2 \times 10 \times 3.65)$

$$\frac{15677 - 20 \times 3.65 \times 15.69}{3920 - (4160 - 1142)} = \frac{}{73} =$$

12.3 ft.

With this information we may now design the shape of the footing. (See Fig. 4.)

The depth of the footing is governed by the shear along the line c—c— and is equal per foot to the area of a strip one foot wide and 3.65 feet long multiplied by the soil pressure = 14,000 lbs.

Safe resisting value of concrete to shear = 60 lbs.

Therefore, resisting shear = 60 lbs. × 22 × 12 = 15,840 lbs.

Therefore the assumed thickness of 24″ is correct.

The area of steel in the footings is found in a way similar to that used previously in simple footings. The reinforcement is placed in one direction only in footing "A" and that at right angles to the beam and both ways in footing "B."

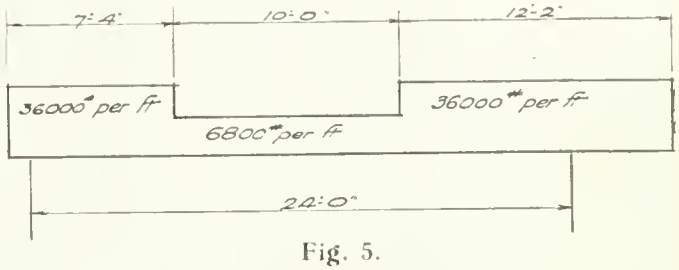

Fig. 5.

In the design of the beam, we have to consider the loading, as shown in the diagram (Fig. 5), found by the method already described. The span of the beam is figured as 24′ 0″.

$$\text{Let reaction} = \frac{36000 \times 7 \times 18.12}{24} = 190{,}000 \text{ pds.}$$

$$\frac{6800 \times 10}{2} = 34{,}000 \text{ pds.}$$

$$\frac{36000 \times 6.08 \times 300}{24} = 27{,}750 \text{ pds.}$$

$$\text{Total} = 251{,}750 \text{ pds.}$$

Maximum bending moment will occur at centre of span and $= (25175 \times 12) - (36000 \times 7.3 \times 8.66) + (6800 \times 5 \times \frac{5}{2}) = 833{,}000$ foot-pounds.

$$\text{Area of steel} = \frac{833000 \times 12}{.86 \times 160 \times 46} = 15.72 \text{ sq. in.}$$

This result is the area of steel required for the entire width of beam.

Therefore, area required per foot of width $= \frac{15.72}{1.7} = 9.25$ sq. in.

As the available depth of concrete will not develop this steel in compression it will be necessary to place additional steel in the compressive side of the beam.

The above is only one of a number of ways of arriving at these results and, as mentioned previously, only one of a number of accomplishing the desired end. It may, however, be stated in conclusion that the type of footing designed by this method has been recently employed in numerous buildings with unvarying success.

PURIFICATION OF SEWAGE EFFLUENT.

By Gilbert J. Fowler and E. Moore Mumford.

IT will hardly be disputed that the most costly part of a modern sewage works, certainly in capital expenditure and often in revenue charges, is the filtration area. Just as the difficulty of land treatment of the sewage of large cities forced on the consideration of more compact processes, so these in their turn are becoming impracticable when great centres of population have to be considered. This conclusion was impressed upon the senior author of this paper when called upon recently to report on the proposals of the Metropolitan Sewerage Commission of New York for the disposal of the sewage of that city. This conclusion was shared by his colleague, Mr. J. D. Watson, who reported simultaneously from an engineering point of view.

The area and cost of filter-beds depends mainly, it will be found, on the amount of colloidal matter present in the sewage, and much confusion of ideas is probably due to the fact that the ordinary sewage filter, be it contact or trickling, is called upon to do two entirely different things at the same time—viz., on the one hand to oxidize, granulate, and finally discharge as humus the colloidal matters present, and on the other to oxidize and nitrify substances in true solution.

A very open grade deep filter is best suited for the first purpose, a shallow fine-grained filter is the most economical for the second. It is true that a tank effluent well clarified by sedimentation can, by accurate distribution, be very efficiently purified on filters of fine material, but even then the area and cost involved when exceptionally large works are under consideration make the problem a very serious one. For these and other reasons the thoughts of many workers in sewage treatment have been turned to the possibility of more efficient removal of colloidal matter before the filtration process.

Hitherto almost the only practical method has been heavy chemical precipitation. The cost and difficulty of this process when really efficiently carried out (and it should be emphasized that a mere perfunctory addition of a few grains per gallon of precipitant is money thrown away) become very great as the volume of sewage increases. Not only are enormous quantities of chemicals necessary, but the disposal of the vast volume of resultant sludge, without menace in some way to the community, becomes increasingly difficult and costly.

The thought which has been in the minds of the authors of the present paper has been to find a method of obtaining a thoroughly clarified effluent without the use of large quantities of chemicals and with the minimum production of sludge. By a thoroughly clarified effluent is meant one which will not eventually deposit solid matter either on the bottom of a stream into which it flows or in the interstices of a bacterial filter. It is clear that in a sewage filter a combined oxidation and coagulation of the colloidal matter must go on, resulting in the production of the so-called residual humus, which either is collected in humus tanks or is periodically washed out of the medium. If this oxidizing and coagulating process could be brought about by suitable open-tank treatment before the filtration process, it is obvious that the latter could be enormously accelerated, if not dispensed with altogether, and the whole operation of sewage treatment could be conducted on a much smaller area.

In the course of a research on another matter, one of the authors had occasion to study the reactions of an organism occurring in nature in pit water impregnated with iron. This organism is a true facultative organism, preferably an aërobe, and exercises a specific action on iron solutions.

The action of the bacillus on iron solutions proceeds in two stages, in which the aërobic and anaërobic actions appear to be symbiotic, at any rate under the conditions occurring in nature. The aërobic action is to precipitate ferric hydroxide from iron solutions, while the anaërobic action is to transform the hydroxide thus precipitated into bog ore, with partial reduction of the iron to a ferrus state. It was found that in order to precipitate the iron sufficiently the organism required a certain proportion of albuminoid organic matter. It was therefore natural to expect that ordinary sewage matter could be utilized in this way. Experiment, in fact, showed that a sewage effluent could be effectively clarified in this way when acted upon by this organism in presence of small quantities of ferric salts, aërobic conditions being maintained in the liquid by means of a current of air.

The process, therefore, by which it is proposed to clarify sewage is, in the first place, to remove the grosser solids, either in a plain sedimentation tank, an Emscher tank, or a Dibdin slate bed, in such a manner, i.e., as shall give rise to the least amount of putrefactive change in the liquid portion of the sewage. The effluent from this preliminary process would be led into a second tank, where it is inoculated with the organism, a small dose of ferric salt is added, and air blown through till clarification sets in. A period of settlement is then allowed for precipitation of the coagulated matter, and eventually the clear liquid is run off, either for rapid final filtration or for direct discharge into the stream. The precise mode of action of the organism is not yet fully worked out, but it seems likely that simultaneous precipitation and solution takes place, some of the organic matter being converted into amido derivatives, and some being coagulated and thrown down with the ferric hydroxide.

The ordinary methods of sewage analysis fail to reveal the change which has really taken place during this process, as they do not differentiate between organic and nitrogenous material in the colloidal and crystalloidal states respectively. It should be pointed out that a fairly strong solution of amido acids, which are the end products of protein degradation, is not necessarily putrefactive, though they require oxygen for their final conversion into nitrate. A recent unpublished research by Mr. R. M. Beesley, a co-worker of the authors, has shown that there is no great difference between the rate of oxidation of substances such as uric acid and glycin, and simpler bodies such as urea. It may be anticipated, therefore, on all grounds, that the clarified liquid resulting from the process as above described can be oxidized at a very rapid rate.

As the conditions during the process are maintained, as far as possible, aërobic throughout, and there is always a certain amount of ferric hydrate present to oxidize offensive sulphur compounds, it is not anticipated that the aëration can give rise to nuisance, and none has been observed in laboratory trials where these conditions have been fulfilled. Experiments in the laboratory witb quantities up to four litres have shown that it is possible to clarify a strong fæcal emulsion in this way.

* From a paper read at the Exeter (England) Congress of the Royal Sanitary Institute.

A limpid, sparkling and non-putrefactive effluent was obtained from domestic sewage drawn from a sewer near the laboratory. Ordinary tank effluent from the Manchester Corporation sewage works at Davyhulme has been rendered non-putrefactive on incubation. So far only approximate estimates can be given of the amount of iron salt required and the duration of the blowing process. Experiments would indicate that 1 grain of iron-salt per gallon is the maximum need, and that a total of twelve hours' tankage—i.e., six hours' aëration and six hours' settlement—will be sufficient.

As regards the inoculation of the organism, once the growth has been established in a tank there appears to be no difficulty in maintaining it. The fact that large bodies of water in the old colliery workings at Worsley, near Manchester, are teeming with the organism, is sufficient evidence of its vitality. An experimental plant has been erected at the University of Manchester which will permit of accurate observations of this process to be made, and sufficient data to be collected to serve as a basis for work on the larger scale. It is already evident that the conditioning factor is the cost of an air blast; the pressure of air will, of course, depend simply on the depth of water to be blown through, and a number of engineering conditions will naturally affect this part of the problem.

It is reasonable to suggest that much of the power required could be obtained on the one hand from gas collected from the fermentation of the main bulk of the sewage solids, either in Emscher tanks or by some kindred process, or the fall available from the aërating tank might often admit of the water-head being turned into power. In any event the authors believe that they are justified in bringing the idea forward at this congress in order that it may be discussed from different points of view.

Experiments on the aëration of sewage in different ways have, of course, been made by different observers. Dr. Dupré and Mr. Dibdin, in Vol. 2 of the Report to the Royal Commission on Metropolitan Sewage Discharge, in 1884, describe a large number of experiments on the aëration of London sewage. In 1888, Mr. Hartland, in conjunction with Mr. Kaye-Parry, patented an aëration chamber for purification of tank effluent. In 1892, Mr. Sydney R. Lowcock conducted experiments on the aëration of filter-beds by a forced air supply. Dr. Adeney's long series of careful researches have thrown great light on the chemical changes occurring when sewage is completely oxidized by prolonged aëration. In 1897 one of the present authors carried out extensive experiments on the aëration of tank effluent under various conditions, and recently Messrs. Black and Phelps have carried out a number of experiments on the aëration of New York sewage, while the subject is also being studied by the chemists of the Massachusetts State Board of Health.

The advance claimed in the present communication is the use of a specific organism found in nature, together with iron salts, to effect the clarification of the effluent—that is, the coagulation of the colloidal matter as distinct from the purification of the effluent taken as a whole. To use a simple illustration, the addition of a little rennet does not appreciably alter the composition of milk as a whole, but separates it into a solid and liquid portion. The endeavor of the authors has been to obtain a similar result in the case of a sewage tank effluent; to collect the precipitated colloids, and purify the liquid portions by high-speed filters, or it may be in large tanks stocked with suitable aquatic plants.

PUBLIC HEALTH MEASURES IN QUEBEC.

Public health legislation in the Province of Quebec began in the reign of Louis XVI., when Canada was still under the French regime. The system has been steadily extending since Canada passed under English domination in 1795, until the present decade, which has witnessed a marked spread of recognition and power.

The provincial by-laws concerning municipalities, establish a standard which all municipalities have to obey, but in no way prevents them from making municipal regulations, which would be more adapted to their needs, provided that, in the opinion of the Provincial Board of Health, such municipal regulations are at least equivalent to the provincial provisions.

In October, 1909, the Board organized a sanitary engineering division, which took charge of waterworks and sewerage systems, and which makes a systematic sanitary survey of all the rivers of the province. Up to date, the Ottawa River, the des Prairies River, and the Richelieu River have been surveyed.

In 1910 it was decided to divide the province into ten sanitary districts, six of which have since been organized, with an inspector located in each.

At the present time careful attention is being given to the important question of the pollution of streams. As so many of the cities and towns of Quebec are using these streams to supply the citizens with the water necessary for drinking and domestic purposes, it is regarded by the Provincial Board of Health as absolutely imperative that proper legislation be enacted to prevent streams being polluted to such a degree that it might increase unfairly the burden of the municipalities which have to go to these streams for their supply of water.

TUNGSTEN.

The tungsten bearing mineral scheelite has been found at a number of localities in Canada, but the only place at which it has been worked commercially is at Scheelite Mines, Moose River district, N.S., according to report by J. McLeish, in Economic Minerals and Mining Industries of Canada. Here it occurs in quartz veins cutting the quartzites and slates of the gold bearing series. The quartz veins also carry mispickel and several other minerals but are not gold bearing. A mill has been erected and about 15 tons of concentrated ore (72 per cent. sheelite) have already been shipped. Sheelite also occurs in the Malaga gold mining district, Halifax county, while at one locality near South East Margaree in Inverness county, C.B., from 300 to 500 lbs. of hübnerite (Fe, Mn) WO_4 were recovered from a large detached mass of quartz. The mineral has also been noted at New Ross, in Lunenburg county, and at Perry Lake, West Waverley, Halifax county, N.S.

In the province of Quebec, scheelite has been found in Beauce county, in a quartz vein traversing Pre-Cambrian rocks, while in Ontario it is found occurring in small nodular masses in parts of the veins around Pearl Lake, Porcupine gold mining district.

In British Columbia its occurrence has been noted in quartz veins on the Meteor claim, Slocan City mining division, West Kootenay, and also in the Cariboo district at Hardscrabble creek where the scheelite appears to be very irregularly distributed in the country rock.

In the Yukon territory at Dublin gulch, scheelite is encountered in small water worn nodules of yellowish color, which are caught in the sluice boxes at Highet Creek.

The mineral is employed in the steel manufacturing industry making a tungsten steel of high tensile strength.

GOVERNMENT ELEVATOR AT PORT ARTHUR.

THE construction of the Dominion Government grain elevator at Port Arthur has reached the final stages and the structure is just being put into commission. The machinery is practically all installed and the high potential power line into the plant is almost completed. Tracks have been laid to give the Canadian Pacific and Canadian Northern access to the elevator and arrangements will shortly be made to give the Grand Trunk Pacific Railway a similar connection.

The elevator is of reinforced concrete construction throughout, except that in the walls of the working house brick panelling is used in a skeleton of reinforced concrete. This latter construction was used to facilitate rapid erection of the house, and adds to its appearance as well. No inflammable material is included in either building or machinery.

The elevator will be operated by electric power throughout, and a separate motor has been installed for each machine. Twenty cars can be unloaded simultaneously, the unloading capacity of the house being about forty cars per hour. An interlocking device connecting the valves of the car hoppers prevents any possibility of mixing the contents of one car with those of another. The normal loading capacity to boats will be about 75,000 bushels per hour, but for the first hour this can be increased to 115,000 bushels.

The Government Elevator at Port Arthur in Course of Erection.

The working house towers to a height of 185 feet above the water level. It contains seventy-five circular bins of about 7,000 bushels capacity each, fifty-six interspace bins of 3,000 bushels and thirty-six outer-space bins of 1,500 bushels capacity each. Its total capacity is about 750,000 bushels. The storage house has seventy circular bins, each 24 feet in diameter and ninety feet in height of 30,000 bushels capacity, together with fifty-four interspaces of about 8,000 bushels capacity each. The total capacity of the elevator is 3,250,000 bushels. In designing the elevator especial provision was made for a large number of bins of small capacity for storing small lots of grain that may require separate binning.

The working house is equipped with ten hopper scales of 2,000 bushels capacity, with a garner of equal capacity over each scale. The elevator legs are as follows: five for receiving, five for shipping, five for cleaning, one for screenings, one for drying, one for oats, and two for flax. Fifteen sets of receiving cleaners are provided for cleaning oats, wheat and barley, and fifteen additional cleaners can be installed when they are needed. Special machines are also installed for separating oats from wheat, in addition to two screenings separators and two flax separators.

At the south end of the working house a drying plant is installed in a separate building. This has a capacity of 48,000 bushels per day, and is for drying damp, tough or wet grain, and putting such grain in condition for storage.

A revetment wall is being built around three sides of the site, which contains about 32½ acres. The site was formerly covered by water, but is now being filled in level

Another View of the Structure.

with the top of the revetment wall. A slip 1,200 feet long will provide ample space for the largest lake boats alongside the working house. Four lines of railroad tracks extend through the house and beyond it for a distance of 800 feet, so that eighty cars can be spotted at one time, and taken into the house by the car pullers. Provision has been made for increasing the capacity of the elevator to a total of ten million bushels, should additional capacity be required, and the site affords ample space for increasing this capacity still further.

The production of peat in 1912 in Canada given in Mr. McLeish's report on Economic Minerals and Mining Industries was 700 tons, and was valued at $2,900.

The total production of pig-iron in Canada in 1912 was 1,014,587 short tons and of steel ingots and castings 957,681 short tons. That the domestic production is insufficient to meet home demands is indicated by the large imports which in 1912 exceeded 1,300,000 tons of pig-iron, ingots, blooms, etc., plates, bars and rods, structural steel, rails, pipe, nails, wire forgings, castings, etc. The opportunity in so far as the market is concerned for the development of Canadian iron resources is evident.

The Eighth Annual Convention of the Federation of Trade Press Association in the United States will be held at the Hotel Astor in New York, September 18th, 19th and 20th. It is expected that a great majority of the technical and trade journals in Canada will be represented. Relative to journalism of this nature, it is stated that the capital invested in trade journals in the United States has been estimated at not less than $50,000,000, and that the Federal papers represent a capital investment of more than $35,000,000. The Federation was organized in 1906. At the start it concerned itself chiefly with press problems, but in later years more consideration has been given to ways and means of promoting best interests of the trade press in many other directions. Managers, manufacturers and advertising men interested in the idea of business promotion through trade press efficiency, which are to be featured at the coming Convention, should consider well the invitation to attend, as there will be papers and addresses to all these, as well as to paper and book publishers.

WATERWAY STRUCTURES.*

By A. R. Hirst,
State Highway Engineer of Wisconsin.

Among the most important considerations affecting the construction of public roads is that of drainage. The life of every road structure depends upon the drainage given it, and the culverts and bridges necessary must be built not only to serve the purpose of drainage, but must serve also the convenience and safety of travel. The failure of a road results only in the additional expence necessary to replace it in proper condition, but the failure of a bridge results also in the suspension of travel, and if it occurs at the wrong moment, may cause considerable loss of property and possibly injury or death to those travelling the road.

For many years both the design and erection of highway bridges was practically entirely in the hands of the steel bridge companies, who used their opportunity to the utmost, an decorated the landscape with structures which had little to commend them except the fat prices they brought from an unknowing public.

Within the last few years, however, many States have created highway commissions which have effectually taken up the problem of bridge design, and a considerable change for the better has occurred, both in the strength of bridge superstructures and in the foundations, more especially in the latter, which was the place where most of the older structures were especially deficient, if one point of weakness can be selected from the mass of general ineffectiveness.

A properly designed waterway structure should fulfil the following requirements:—

1. Waterway sufficient to carry off promptly the water coming to it.
2. Proper foundations to bear the loads, resist undermining, and give long service.
3. Superstructure designed to bear for a long period of years any load which may legally be imposed upon it.
4. Superstructure wide enough and so constructed as to serve the comfort and convenience of travel.
5. Economy of maintenance.

A sixth factor, that of æsthetic design and fitness of the structure to the surroundings, has been and is little considered in bridge and culvert design, but will probably be demanded more and more as public appreciation of the value of pleasing design grows.

In the short compass of this paper we cannot enter into a discussion of bridge design, or give any details of any specific type of structure. We will, however, give some account of the standard practice in the State highway work in Wisconsin, and probably this will be sufficient evidence as to what constitutes a proper waterway structure.

Wisconsin is a State-aid State, and gives State aid to bridges and culverts, as well as to road construction. All waterway structures 6 feet and under in span are classed as culverts, and are built out of the funds available for the construction of the road. All waterways structures over 6 feet in span are considered as bridges, and must be provided for by separate appropriations, the State paying 20 per cent. of their cost instead of 33 1-3 per cent. as in the case of culverts on roads.

Wisconsin has a drastic bridge law, which provides that culverts under 18 in. in span must be so constructed or reconstructed as to stand without planking a load of 18 tons, and waterway structures over this span must be designed, "in accordance with standard engineering practice," to stand a load of 15 tons without planking.

In addition to the duty of designing all State-aid bridges and culverts, the State Highway Commission has imposed upon it by law the duty of approving as to their safety and engineering sufficiency the plans of all bridges constructed with county aid. In the seven seasons of the existence of the Wisconsin Highway Commission and its predecessor in highway work, the Wisconsin Geological and Natural History Survey, we have designed about 1,000 highway bridges of a span exceeding 10 feet for counties, and about 400 bridges exceeding 6 feet in span, and innumerable culverts under this span for the State-aid construction. In addition to this, we have approved the plans for probably 500 bridges not designed by our engineers, but simply checked as to engineering sufficiency. Actual culvert and bridge construction under our own designs has cost about $2,000,000.

We may roughly divide our bridge superstructures into five classes as follows:—

Class 1.—*Spans from 18 inches to 10 feet.*—Almost invariably constructed of reinforced concrete of the slab type. We are building even the smallest culverts of reinforced concrete, as we find in Wisconsin that they are entirely serviceable, easily constructed, and in probably 50 per cent. of the cases cost less than any other type of culvert except wood, which is not allowed on any of our work. The smallest concrete structure we are now building is 18 in. x 12 in., as we have found the smaller sizes equally as expensive and very easily blocked with ice and debris.

In some cases where the foundation conditions are extraordinarily soft and difficult, or concrete materials are not reasonably available, we use culverts of corrugated metal with concrete or stone end walls, but such culverts are used only where it is impracticable to use concrete, and probably not 1 per cent. of our culverts are now built of this material. Vitrified clay is not used at all on State-aid work, as they have been found almost invariably to crack by filling and freezing. Concrete pipes moulded in place and afterwards moved to the job are not used for the same reason. Under conditions favorable to their use, both make excellent culvert, and we could recommend them in less severe climates. Cast-iron water pipe has not been used on account of its cost, which invariably exceeds that of concrete.

We find in the small concrete culverts from 18 inches to 10 feet the average cost per cubic yard complete, including the excavation and back-filling, is about $8.00, and very seldom runs above $10.00 per cubic yard; sometimes as low as $6.00.

Class 2.—*Spans 10 feet to 40 feet.*—Either reinforced concrete, the slab type up to 18 feet and the through girder type up to 40 feet, or I-beam structures with concrete floors are used. We are building many true reinforced concrete bridges, but with public lettings open to any bidder, the workmanship and finished appearance has been so poor in many cases that we are using more I-beam structures than we otherwise would. In the case of I-beams, a five-inch concrete floor is placed on top of the I-beams, and the corrugated arch type of support for the concrete between the I-beams is but seldom used.

Class 3.—*Spans from 40 to 80 feet.*—We are using the Warren riveted pony truss practically exclusively, though a few plate girders are being used where the conditions of hauling are favorable. All of these structures have concrete floors.

* Read at American Road Congress, held at Detroit, Mich., September 29th to October 4th, 1913.

Class 4.—*Spans from 80 to 135 feet.*—We use the riveted Pratt high truss with a horizontal top chord, also with a reinforced concrete floor.

Class 5.—*Spans over 135 feet.*—We use a Pratt riveted high truss with a curved top chord. Practically all of these larger spans are also built with a reinforced concrete floor. Very seldom do we use a pin connected truss, either for Class 4 or 5, probably not once in twenty-five cases.

From our cost figures on all bridges so far constructed, we find that for any span the price erected (including substructure and superstructure) figures out very closely to $40 per linear foot of the over-all span. Reinforced concrete floors average about 20 cents per square foot. Steel in plate girder and truss spans averages from $25 to $70 a ton erected, and I-beam spans figure from $50 to $60 a ton erected.

Widths of Structures.—We have adopted for widths for concrete culverts and bridges the standards recommended by the Association of State Highway Department, which are as follows:—

First Class Roads.

Culverts under 12 ft. span, minimum width	24 ft.
Slab bridges over 12 ft. span, minimum width	20 ft.
All other concrete spans, minimum width..	20 ft.
Very long bridges less if necessary.	

Second Class Roads.

Culverts less than 12 ft. span, minimum width	20 ft.
Slab bridges over 12 ft. span, minimum width	18 ft.
All other concrete bridges, minimum width.	18 ft.

Third Class Roads.

Culverts less than 12 ft. span, minimum width	20 ft.
Slab bridges over 12 ft. span, minimum width	18 ft.
Longer bridges may be, minimum width....	16 ft.

Steel bridges are built almost invariably with a 16-ft. roadway; that is, 16 ft. clear distance between trusses or rails, no matter what the class of road, although for spans under 80 ft. some 18-ft clear roadways have been built.

Abutments under practically all structures are plain concrete, as with concrete materials as cheap as we have them in Wisconsin, and with the difficulty of getting first-class workmanship in reinforced concrete foundations without constant inspection, we find that this is the cheapest type of abutment. Occasionally cement rubble masonry abutments are used, and once in many times driven steel I-beam piles surrounded by a concrete wall are used. The last type of abutment has been found to be very satisfactory and economical for high abutments on sandy bottoms, and has largely displaced the use of cylinders with steel backing. Steel backing is not allowed on any State-aid structure. The price of concrete in bridge abutments and piers averaged last year about $8.00 per cubic yard.

A large share of the trouble with bridge structures results from improperly designed foundations. A common fault is stopping work before a proper depth below stream bed is reached. Seldom should foundations extend less than four feet below stream bed, and whenever doubt as to the bearing power of the soil at that point is entertained, or as to undermining from a rapid stream, they should be carried down to solid soil or thoroughly piled. All foundation work should be inspected as the excavation is made and material is placed, not necessarily by an engineer, but at least by an honest man with good judgment and backbone. All concrete work in any part of the structure should be inspected as it is placed. Inspection of steel and workmanship on it as it is erected is not so necessary, as it can be inspected and its compliance with the specifications determined after erection at the time acceptance is to be given.

As to methods of letting the work. We have found it necessary to have open competition and sealed bids on bridge work, and by asking for mailed bids on all work have established true competition, and have to a very large extent broken up the old system of "pooling," and combinations of the bridge agents who may be on the ground at the letting. We furnish complete plans for foundations and for reinforced concrete, I-beam and plate girder spans, and all bidders submit prices on our uniform plans. For truss spans, we furnish the truss diagram showing the stresses in the truss members and the make-up of the truss members, floor system, and principal connections, and the successful bidder submits for approval the shop drawings before fabrication is commenced. For trusses, we believe the latter system is preferable to that of furnishing complete shop drawings, as it allows manufacturers to follow their standard shop practice in detailing so long as these details are satisfactory.

The proper design for culverts and bridges is an engineering problem which should always be left to engineers. Probably a State highway department can handle it more economically than can private engineers, as so many bridges will be built of one span that superstructure plans can be standardized, and even the same foundation plan may fit several bridges. The cost of designing, letting and accepting bridges in Wisconsin has averaged about 3½ per cent. of the total cost. Inspection has been paid for separately by the local units. It would probably be better to have a State inspector on each bridge, but we have gotten very good results through local inspection at probably 25 per cent. of the cost of placing a man on each job. Important jobs should have a skilled inspector by all means.

MODERN DITCH DIGGING.

Machines are rapidly supplanting manual labor in digging trenches for water mains, sewers, irrigation, etc. The illustration below, which was made from a photograph taken by Willis Chipman, C.E., of Toronto, shows one of many different types of modern trench diggers. These machines have been especially successful in Western Canada, but are gradually coming into great favor in the East, also, for all large contracts where the material to be excavated does not contain too much stone of large size. Among the many types of these machines, the best known in Canada are the Parsons, the Austin, the Harris, the Monahan, the Potter, and the Carson excavators.

STREAM FLOW IN SEWAGE DISPOSAL.

On another page reference is made to a recent publication of the Royal Commission on Sewage Disposal, which body, acting under the direction of the British Government, has attempted to present standards of purity of sewage effluents and streams to serve as a guidance in the installation of sewage treatment plants and the disposal of sewage by dilution. These standards are not definitely fixed and may be varied at the discretion of a central authority.

In America no concerted effort has been made to establish standards to regulate the use of streams and lakes as receptacles for sewage and sewage effluents, although various fundamental principles have been suggested, based largely upon observations of existing conditions. For instance, it has been determined by various investigators that untreated sewage must receive a dilution of from 3.5 to 6 cubic feet per second per thousand persons tributary to avoid objectionable conditions. Another authority has tentatively suggested a formula to determine the safety of discharging sewage into streams used for water supply purposes, and various other ill-defined standards have been suggested.

While commenting upon the standardization of dilution of sewage, the Ohio State Board of Health recently expressed the hope that provision would be made at an early date whereby an accurate and comprehensive knowledge of the streams of that State might be made available. The same applies generally to Canada, and particularly to the Province of Ontario.

The fundamental factor which is required in the application of any standard is the volume of flow of the stream considered. Little is known of the actual flow of streams in this country, although the Hydro-Electric Power Commission has been carefully accumulating data for several years, in connection with power investigation. The United States Government has attempted to obtain this very important information for sewage disposal purposes, in addition to similar statistics which have been collected with respect to power development during the past half century. In the proper consideration of problems attending the disposal of sewage, such a knowledge of the flow of streams is absolutely necessary.

Ontario's sewerage problem is one that cannot be satisfactorily solved by the application of systems such as have been evolved for the disposal of dangerous effluents in European cities. Although the standard of purity attained in Birmingham, England, and in Essen, Germany, is for the world to admire, the cities bordering upon Ontario waters have entirely different conditions to meet, and such systems, although the most scientific that have yet been developed for the handling of sewage, would be quite inefficient here. One reason for this is that the water of our rivers and lakes is restricted and is not subject to the beneficial influence of tides.

Not a few Canadian cities are taking chances in the matter of water supply, because of the effluents from their own or neighboring sewers, and as the seasons come and go these effluents assume greater proportions, Nature being expected to extend her purifying agencies to an ever-increasing degree. It is to be hoped that the study which the provincial departments of public health are making will bring forward many requisitions in this matter, tending toward greater care and safety.

Disposal by dilution should be carried out only under scientific methods. Absolute surety of a generous factor of safety is essential for healthful and wholesome water. The sentiment that is associated with the question of water supply should not be entirely disregarded, either.

And, science in the matter of disposal by dilution must have, as a basis, an accurate and comprehensive knowledge of stream flow. When Canada has acquired this necessity, to it may be applied certain safe and standard rules governing the degree of purity which an effluent must possess before its entrance into our streams and lakes should be permitted.

CANADIAN OIL RESOURCES.

It is said that the British Admiralty is endeavoring to ascertain the extent of oil deposits within the Empire, with a view to securing requisite supplies for naval purposes. It is also stated that from present knowledge of Imperial oil lands, the supply will be derived mainly from shale rather than from wells yielding liquid petroleum.

At the present moment interest is centred upon the enormous deposits of oil shale which are known to exist in Albert county, New Brunswick. These deposits have been known to exist for a long time, though they have not been worked hitherto on any large scale. Now, however, these shales appear to have become of inestimable value, capable of yielding from 27 to 48½ gallons of fuel oil per ton of shale. The reports of English experts, as well as those made by the Geological Survey of Canada, show that, without doubt, there are between 200,000,000 tons and 300,000,000 tons of shale in one section alone of the Albert fields; so that a calculation on the basis of 40 gallons per ton means a supply of fuel oil of 10,000,000,000 gallons, or 40,000,000 tons. Another important point about the shales of New Brunswick, also, is that they are very easily and economically worked, and it is estimated that fuel oil derived from these can be supplied at a very low rate, in consequence of the fact that the oil shale may be obtained by open pit mining. By this means it is stated to be possible to provide 2,000 tons per day for over one hundred years. Apart; however, from this bed, there are other deposits north and south which are as rich in shale as the deposit referred to.

In Western Canada even greater interest is being shown toward the newer sources of fuel, and activities in the quest of oil and gas are assuming importance. Reference is made in another column to the report upon the prospective wealth of these fields, by Mr. Wyatt Malcolm. In this connection it is worthy of note that one large stretch of country being very actively prospected at the present time is that of the Province of Alberta. In consequence of the recent discoveries of asphalt and natural gas deposits in various parts of the Western Provinces, an active campaign has set in among prospectors and experts, who are making an exhaustive search for indications of oil in Central and Southern Alberta. The experts of the Dominion and Provincial Governments are engaged in this work of prospecting and mining, and drilling outfits have been shipped from Edmonton recently. The wells which have been put down are at the present time over 2,000 ft. in depth, and there is a sanguine feeling that good results will be obtained at an early date. The Canadian Pacific Railway is keenly interested in the development of these new sources of fuel supply in the West, especially oil. Drillers are at work close to the railway at Calgary, in the Athabasca and Peace River territories, and at a number of different points on the Pacific Coast. Enlargement of storage facilities in the neighborhood of Vancouver is also contemplated, as larger quantities of liquid fuel are being purchased for use upon their passenger steamers on the Pacific.

Mr. Malcolm, in his report, calls attention to the possibilities of the Western part of Canada as an agricultural country, in which towns are rapidly springing up as distributing centres and villages growing into cities. With an increase of population will come an increased demand for material for light and fuel, so that, taken altogether, the finding of a market for oil and gas will be an easy problem, and the demand will be sufficient to greatly stimulate the effort of drillers.

COMMISSION CONTROL OF ONTARIO WATER-POWERS.

"In view of the comprehensive schemes outlined by the Dominion Government for the creation and improvement of waterways in connection with the St. Lawrence River, Welland Canal, French River, Sault Ste. Marie, Trent, Ottawa and others, involving a large expenditure of public money; and in view of the extensive power developments which are possible in consequence thereof; also, in view of the rapidly increasing power requirements of the Province, be it resolved that this Association request the Dominion Government to put all such waterpowers under the jurisdiction of the Hydro-Electric Power Commission of Ontario, to be developed by them for the use of the municipalities of the Province for the benefit of the people."

In adopting this resolution at its recent convention in Toronto, the Ontario Municipal Electrical Association, a body whose membership consists chiefly of mayors and aldermen of various cities and towns of Ontario, fairly representative of the whole province, has expressed a general note of disapproval against control by private corporations of the valuable assets to be developed from waterpowers. The resolution is going forward to the Dominion Government in the form of a memorial, it being pointed out by those prominently in support of the action, that it frequently happened that the control of these powers passed on to private companies before the people got a chance to express any wish to control them for themselves.

The Hydro-Electric Power Commission of Ontario has, by request of various municipalities, exercised its judgment over a number of proposed developments throughout the Province, and already a great deal of unnecessary expenditure has been averted by its timely investigation.

In the establishment of a power service there are many features, especially in connection with mechanical and electrical details, that are more or less of a stereotyped nature, and apply to all plants with approximate equanimity. But these factors are governed by and depend upon the quantity, consistency and other characteristics of the available water supply. It is to be regretted that the present accelerated movement toward a wider use of the waterpowers of the Province for electrical energy is not in possession of stream flow data extending back through a greater period. Except for the past few years, a cursory knowledge based upon the memory and integrity of the "oldest inhabitant," is too frequently the only available information bearing upon the conditions in the past that are of great importance. The result is that there have been plants installed that are quite out of proportion with the available supply of water; and in the prevention of similar occurrences the Hydro-Electric Power Commission is rendering a service that is being felt. Further, the records which it commenced several years ago to acquire relative to Ontario stream flow emphasize the fact that the matter of the resolution referred to above is quite in keeping with the object which promoted it.

EDITORIAL COMMENT.

It is now several months since the position of city architect was made vacant in Toronto. The Board of Control is at last considering the appointment of a successor to Mr. McCallum.

* * * *

In discussing the question of Canadian freight rates, Mr. Ben. H. Morgan introduced the subject of Canadian duties on British machinery, steel and iron girders, and heavy material of that class, stating that if concessions, by way of reduction or abolition, were made in the tariff with respect to these items, the resulting attraction of British goods to the Canadian market would assure such a freightage in the direction of Canada that British tramp steamers would be encouraged at once to ply between British and Canadian ports. Without the tramp steamer low freight rates are claimed to be an economic impossibility at present.

* * * *

The Burrard Peninsula Joint Sewerage Board was constituted last month by the Provincial Government of British Columbia. It consists of a chairman and four members, all appointed by the Government, the chairman receiving a salary of $5,000 per annum and the members $600. The latter are nominated by the four municipalities in the Sewerage District—Vancouver, South Vancouver, Point Grey and Burnaby. The Board was appointed to construct and operate a system of trunk sewers, interceptors and outfalls on the lines laid down in Mr. R. S. Lea's report to the Joint Committee, the construction of the subsidiary sewers being left in the hands of the municipalities, who must submit all plans to the board for approval. The Board controls an area of nearly 90 square miles, and has powers to borrow a sum of $11,000,000, the principal and interest being guaranteed by the Provincial Government. Interest and sinking fund charges will be met by an assessment on the municipalities, who have the right of appeal to the Lieutenant-Governor-in-Council from any assessment made by the Board. The works will be constructed as the necessity arises, and, as much of the territory is at present very sparsely populated, it will probably be many years before the scheme is completed. The Provincial Government and the municipalities concerned are, on the advice of their engineers, profiting by the experience of the older cities of the world, where, in most cases, the sewerage systems, like Topsy, have "just growed," and have to be revised and readjusted from time to time at very considerable expense, together with the abandonment of points of outfall and lines of sewer often before the loan under which they were originally constructed has been paid off.

* * * *

In the organized counties of old Ontario there are 50,000 miles of road, according to a report made by Mr. W. A. MacLean, of the Highways Department of the Provincial Government. A classification would be approximately as follows:

Trunk roads connecting the large towns and cities	2,500 miles
County or leading market roads	6,000 miles
(a) Main township roads	25,000 miles
(b) Secondary township roads	16,500 miles

The roads described as trunk roads are, with the exception of a few connecting links, amongst the most important of the county roads. Main township roads comprise principally the concession roads on which numerous farms front and which converge into and create the traffic of trunk or county roads. Secondary township roads include the little travelled connecting roads.

OIL AND GAS PROSPECTS IN WESTERN CANADA

IN Memoir No. 29-E of the Department of Mines, Canada, Mr. Wyatt Malcolm outlines the prospective industrial field for the production of oil and gas in the northwestern provinces of Canada. This memoir is a compilation of information obtained in great part from the reports of Canadian geologists. The object is to lay before the public what is known regarding the oil and gas possibilities of these provinces. To this end it was thought advisable to present in a concise form the geological conditions to be met, and for the benefit of those who are interested in boring operations stress is laid on the lithology and thickness of the different geological formations. Logs of wells of different localities are also given, and evidence bearing on gas and oil production and possibilities is presented.

The most important areas considered in the report are: (a) the Athabaska River district, where the Dakota sandstones are impregnated with a bituminous substance, a petroleum product, and where gas is known to occur in abundance; (b) the country about Medicine Hat and westward where gas has been found at different horizons but in greatest abundance probably in the Dakota sandstone; (c) the Pincher Creek district where there has been some prospecting for oil.

The plains of Western Canada are underlain by a great body of sediments, nearly horizontal in attitude, and resting on a Pre-Cambrian base. The eastern contact between the Pre-Cambrian rocks and the later formations runs in a generally northwest direction from Lake Manitoba past Athabaska, Great Slave, and Great Bear lakes. In the eastern part of the plains a great unconformity exists between the Palæozoic systems, consisting of limestones, dolomites, and shales, and the Cretaceous system, consisting of shales and sandstones, so that we find the Dakota sandstones of the Cretaceous system resting directly upon limestones of the Devonian system. The Palæozoic strata are exposed by faulting in the Rocky Mountains and much of the later sediments has been eroded, only traces of the lower members being left. In the west, deposition during Carboniferous, Triassis, and Jurassic times has to a great extent bridged over the unconformity seen in the east, and the geological column includes formations found in nearly all the great systems from the Cambrian to the Recent. In western Alberta and in some parts of south Saskatchewan the Cretaceous sediments are overlain by Tertiary deposits. Overlying all is a mantle of unconsolidated Pleistocene and Recent deposits.

Little has been done yet to test the gas and oil possibilities of the district. A few wells have been sunk, and in a number of these gas in commercial quantities has been struck. Prospecting for oil has been less successful.

Prospecting for oil has been carried on in two different areas in the Pincher Creek district, southwestern Alberta, one on the south branch of the south fork of Oldman River, and the other on Oil Creek, which flows into Waterton Lake. This has apparently resulted in no great measure of success. In northern Alberta the Dakota sandstone, where exposed along the Athabaska and its tributaries, is impregnated with a bituminous substance believed to be a petroleum product, and it is thought that liquid petroleum exists in this porous rock at some distance from the outcrop. To test the validity of this belief, wells were drilled during the nineties by the Dominion Government at Victoria on the Saskatchewan, at Athabaska Landing, and at the mouth of Pelican River. In the first two wells the Dakota sandstone was not reached, while in the last it was reached at a depth of 750 feet, penetrated about 87 feet, and found to carry maltha or heavy, tarry petroleum.

Prospecting for gas has been much more encouraging. The boring at the mouth of Pelican River, although disappointing so far as oil is concerned, proved the presence of a great reservoir of gas in the Dakota sandstones, and heavy flows were struck at 820 and 837 feet. In southern Alberta, also, gas is found in paying quantities. A good field exists at Medicine Hat, and flows have been obtained at several different points west of that city. At Bow Island a flow of several million feet is obtained.

Thus, while the presence of oil in commercial quantities remains to be proved, boring operations have demonstrated beyond a doubt the existence of large reservoirs of natural gas, and it seems probable that further exploratory work throughout the wide area underlain by the Cretaceous rocks should lead to the discovery of other reservoirs.

It is believed that the Devonian limestone is the source of the gas and petroleum products of northern Alberta, while the porous Dakota sandstone forms the reservoir into which they have risen and in which they have been retained by the overlying shales. The Dakota sandstone is the productive formation at the mouth of Pelican River, and it is also believed to be the gas-bearing formation at Bow Island in southern Alberta. As the Devonian limestone and Dakota sandstone are of wide distribution and probably underlie the western part of Manitoba and a great part of Saskatchewan and Alberta the prospects for the discovery of other gas fields seem favorable. On account of the great thickness of sediments overlying these formations, the driller, however, must be prepared to go to a considerable depth.

INCREASE OF "RUN" IN MECHANICAL FILTERS.

IN a paper presented to the American Waterworks Association at Minneapolis Mr. Frederick H. Storer, Bacteriologist and chemist to the Louisville Water Company, has dealt with one of the causes of trouble in mechanical filters.

It is shown that though it might reasonably be inferred that the operation of the mechanical filter would be easiest at times when bacteria and suspended matter are present in the raw water in the least amount, many filter superintendents are finding that such is not always the case, and that warm weather and clear water bring troubles peculiarly their own, shortening the filter runs and producing odors in the filters. At such times the unfiltered waters are found to contain very minute forms of life, diatoms and a few algæ, accompanied by considerable amounts of very fine matter of indeterminate form capable of adhering together in flakes. This matter is supposed to be the result of bacterial action on organic substances. Thus, conditions of clear, warm, shallow water, abundant sunlight and sluggish current afford these micro-organisms the most favorable conditions for development, and their numbers increase rapidly at such times, while the sedimentation basins give the required conditions.

An instance is quoted where, during a period of twenty-six days, the number of micro-organisms present in the unfiltered water remained practically constant; yet during this period the length of the filter runs steadily decreased, and this result was considered as being due to the cumulative effects of a constant number of organisms. When, however, copper sulphate was added to the water in the sedimentation basins there was a general increase in the length of the runs. Also later, when the organisms had died from natural causes, a similar increase in the length of the runs was noted. During this time the degree of turbidity of the water had remained unaltered, and it was found that the length of the filter runs followed quite closely the variations in the number of micro-organisms present. The manner in which the clogging occurred is described as differing from that experienced with water of greater turbidity.

It was at first believed that with waters of very low turbidity, owing to the fact that the size and consistency of the film formed on the filter surface was reduced, the very fine suspended matter was able to penetrate into the sand in a manner which was not the case with water of greater turbidity, and in the absence of any considerable number of organisms the shortening of the filter runs was first attributed to fine turbidity alone. It was, however, found, on microscopic examination, that the sand generally showed the presence of numerous diatoms and other organisms apparently cemented together in a matrix of amorphous matter and fine turbidity, and the author is of opinion that the living organisms accelerate the formation and retention of this gelatinous film upon the sand grains. Practically, the surface of the sand under these conditions became abnormally hard and compact in a short time, and when broken up the sand grains showed a slight tendency to stick together, and this condition could not be wholly corrected even by thorough washing.

Under these conditions it was considered that some method of treatment should be adopted to prevent the clogging, and three methods were tried, though it seems that only one of these—the successful method—received any great degree of care, owing to the difficulties of application under the particular circumstances. The killing of the micro-organisms by chemicals was attempted, but owing to lack of equipment for applying it accurately as a continuously fed solution, hypochlorite was applied to one of the filter beds in the form of powder. This was done by draining off the filter till about 3 in. of water remained on it, and scattering the powder over the surface and allowing the bed to stand thus for twenty-four hours. The result did not prove to be useful, and the bacterial efficiency of the bed was, moreover, impaired. Copper sulphate was then applied in the second sedimentation basin, and in the coagulant basin, and favorable results were at once obtained. The method adopted was that of dragging bags of the copper sulphate through the water. The third method was that of using the river water without preliminary sedimentation, the water being run direct to the coagulant basins. This was done on two occasions, and in both cases encouraging results were obtained, although in each case an increase in turbidity followed within a few days, and thus left no opportunity to see how long the improvement would have lasted.

The summary at the end of the paper states that the water of the Ohio River, when of a turbidity below 30 parts per 1,000,000, almost invariably causes decreases in the lengths of the filter runs. If such turbidities are accomplished by micro-organism and much amorphous matter, still greater decreases follow. Filter runs may be greatly increased by the judicious use of copper sulphate, although aftergrowths of bacteria sometimes follow its application, and must be guarded against. Small doses of hypochlorite of lime do not affect these micro-organisms in such a way as to increase the length of the filter runs. The determination of the time of filtration of samples of water through small laboratory filters will in some instances enable the operator to select the water from that point of his system which will give the longest filter runs.

PRESENT STAGE OF SCIENTIFIC WATER SUPPLY IN AMERICA

REPORT OF AMERICAN SOCIETY FOR MUNICIPAL IMPROVEMENTS' COMMITTEE ON WATER WORKS AND WATER SUPPLY—PRESENTED AT 20TH ANNUAL CONVENTION, WILMINGTON, DEL., OCT. 7TH.

By A. F. MACALLUM, C.E.,
Chairman

IN looking over the legislation of the past year and the greater amount of knowledge on water supply displayed by the press, it must be confessed that the different States and municipalities have not been developing their laws for the proper protection of the people from contamination of water supplies as rapidly as is considered necessary: This has been due principally to the ignorance of the average legislator, and sometimes the political pressure brought to bear upon him from interested sources.

Legislation in Minnesota.—In Minnesota a bill was placed before the State Legislature for adequate protection of the water supply throughout the State. This bill provided that all persons, corporations, and municipalities, other than first class cities, supplying water for private or public consumption within the State must file with the State Board of Health certified copies of plans of their water supply, and that no such source of water supply shall be used until plans have been placed before the State Board of Health and favorably considered. This also applies to new places for the disposal of sewage. This State approval would have been a step in the right direction, and Minnesota, following in the steps of New York, New Jersey, Pennsylvania, Massachusetts, Ohio, and the Province of Ontario, but unfortunately the opposition was so strong that the bill was withdrawn.

Water Waste.—In Philadelphia water is still wasted, and its water system is now heavily overworked, with the result that in attempting to keep up with this waste the quality of the water, along with efficiency and economy in operation, have been sacrificed for the sake of quantity, and the present filters are being worked at a higher rate of filtration than is thought advisable, or that would be necessary under normal restrictions. This applies to other cities also, and the public seem very slow in awakening to the tremendous unnecessary expense, although brought to the fore by probably every manager of municipal waterworks in the country, and every advance made to curtail the water to reasonable limits is only gained after hard and very often bitter opposition.

In New York it was found that 33,500,000,000 gallons of water were saved at a total expense of $138,000.00 by careful house-to-house inspections, which amount was ascertained after careful pitometer gaugings before and after district inspections.

Pollution of Lake Erie.—During the spring a conference was held at Cleveland between the Ohio State Board of Health and representatives from cities on the south side of the lake to discuss the sewage pollution of Lake Erie, and it was thought probable that there was no general pollution of that lake, and that any pollution was confined to zones within limited distances of cities and rivers contributing sewage. It was also brought out that the sewage from any particular city was more detrimental in its effect upon its water supply if taken from the lake than upon that of any other city, taken from the lake, and that water supplies taken from limited distances from the shore should be purified. At this meeting a resolution was adopted asking the State Board of Ohio to investigate the degree and extent of the pollution of Lake Erie, and also a resolution was adopted providing for the appointment of a committee to fix standard methods of analysis of samples and the nature of the determinations to be made in the investigation.

Commenting on this, we may say that, while the pollution would generally be within limited distance of cities and rivers, yet there are authentic cases on these great lakes where islands of polluted water have been found fourteen miles distant under certain weather conditions, which, however, are not common.

Analysis.—In the chemical and bacteriological determination for the purity of water the procedure originally developed by the Massachusetts State Board of Health has almost universally been followed. That analyses estimate the amount of chlorine, nitrates, nitrites, oxygen consumed, oxygen dissolved, odor, turbidity, hardness and sediment, along with bacteria count and tests for B. Coli; yet it has recently been pointed out by Dr. H. E. Barnard, chemist of the Indiana State Board of Health, that in many tests made the values for chlorine, nitrates and nitrites under varying conditions are of little value. For instance, the nitrite factor, of considerable value in the determination of well supplies, is of little value in rivers or lakes, varying more widely during conditions of low and high water than of varying amounts of sewage inflow. The same remarks apply to the presence of free ammonia. It was found, however, that two factors of oxygen consumed and dissolved were of prime importance, although they varied also in rivers somewhat according to the variable flow and by turbidity. However, the determination of these two factors, with the bacterial count and test for colon bacillus, is of great benefit in ascertaining the purity of a water supply at the time the tests were taken; but to be of prime value there should be a large number of tests extending over different conditions of the river or lake, for no chemist can definitely say that any water supply is good or bad upon the result of isolated tests, and without knowing the local conditions and surroundings at the time the samples were taken. We have dwelt on this because of the almost universal idea held that one determination of a water supply is quite sufficient, and of the habit of some chemists of approving or condemning a supply upon such a test and without a knowledge of the locality from which the samples were taken.

In looking over the typhoid statistics of some fifty large American cities a considerable decrease has been noticed, there being only twelve cities in this list where the rate has been greater than last year. This is due, no doubt, to the betterment of the water supplies and the general improvement in sanitary conditions.

Filtration.—The filtration of water is practically limited to two standard methods on this continent—one being by means of graded sand and without the use usually of any chemicals; the other by mechanical methods for treatment with chemicals. Each method gives equally effective results, although the selection of which method adopted is governed generally by local conditions.

In the slow sand method of filtration the water is passed through beds of graded sand and gravel, without the addition of chemicals, at the rate of about four million gallons per acre per day, which at times may be increased 25 per cent. without loss of efficiency. The water is then collected in reservoirs.

With the mechanical system the water is first impregnated with a coagulant, such as sulphate of alumina, and allowed to stand in sedimentation basins for a few hours to allow a sufficient precipitation, after which the comparatively clear liquid is pumped through rapid sand filters at the rate of from 100 to 150 million gallons per twenty-four hours. It is then ready for distribution.

The first cost of mechanical filtration is considerably less than for slow sand filtration, besides requiring much less area for the plant, which ratio of cost will vary according to local conditions—as, for instance, the material upon which the filters are to be built, with the resulting foundations. The mechanical system can usually be built in half the time that is required to build slow sand filters. On the other hand, the cost of operation is largely in favor of the slow sand method, which averages, for operation, about $1.90 per million gallons, while for the mechanical mehod the cost would be about $4.70 per million gallons. This difference is principally due to, and varies with the cost of, the coagulant. This does not include pumping or capital charges in either case, although the additional head required for the mechanical operation is included.

The mechanical method will successfully treat any water, regardless of turbidity or color, while the slow sand method works best when there is comparatively little suspended matter or color.

With the conditions existing at Philadelphia it was found necessary to eliminate some of the suspended matter by means of a roughing filter, which removed a considerable amount of this suspended matter, and allowed the slow sand filter to be operated above their rating. This combination was effective in obtaining results at a lower operating cost than with mechanical filters, and at the same time successfully treated a water otherwise not altogether suitable for the slow sand method.

It might be supposed that mechanical filters would work best when bacteria and suspended matter were least, but many filter superintendents are finding that such is not always the case, and that in warm weather with clear water odors are produced in the filter, with shortening filter runs, caused by clogging of the sand. Examinations of the unfiltered water showed minute forms of life diatoms and a few algæ, accompanied with a fine, flaky matter, supposed to be the result of bacterial action on organic substances. This matter formed a gelatinous firm upon the sand grains, causing the surface of the sand to become abnormally compact, and with a tendency of its grains to stick together, which was not altogether corrected by washing. This clogging was successfully overcome by the judicious use of copper sulphate. After the copper sulphate treatment bacteria increased, probably because it reduced or removed unfavorable conditions, but no B. Coli was detected, and the increase in bacteria was eliminated by adding 0.25 parts per million of available chloride. While this trouble has developed and has been successfully treated at Louisville of the Ohio River water, using mechanical filters, on the other hand, at Toronto, with slow sand filters and Lake Ontario water, it was found that on account of the amount of suspended matter and sand carried to the filters that the filters were almost clogged up. It was also found that from the inset of frost until the warm weather in the spring it was not possible by the means provided to wash the sand scraped from the filter beds. The pipe lines and sand would freeze up during the washing process, necessitating the removal of the sand scrapings until the spring and the washing and re-sanding of the filters. From this we wish to point out that where any installation is contemplated there is need of a very careful study of the quality of the water, the local conditions governing not only the method of treatment to be used, but also the location of the plant.

It has been found that raw water can be treated with seven pounds per million gallons without developing any taste, and if after treating the water can be stored for three or four hours in a reservoir, or aerated, as much as 12.5 pounds per million gallons can be introduced without noticeable taste. It is better to obtain water of the best quality rather than depend upon the efficiency of purifying apparatus, chemicals, and the skill of employees, and in the case of New York a very interesting discussion has been going on as to the advisability of filtration outside of chlorination. Because of the diametrically opposite opinions advanced by the engineers of various municipal bodies interested, filtration outside of hypochlorite treatment was decided against, although it was shown that such treatment did not remove bacteria embedded in particles of suspended matter, decrease turbidity, lessen color or vegetable stain, or remove swamp tastes or odors.

The application of ultra-violet rays for purifying large quantities of water has not advanced very materially during the past year on this continent, although it has been used at Rouen, France, for the past three years. The simplicity of the apparatus, easy maintenance, and high efficiency seems to open a wide field for its application. It is necessary, however, before submitting the raw water to the rays that the suspended matter be removed, otherwise germs protected by such matter do not come directly under the effect of the rays. An ordinary sand filter can be run from five to ten times its ordinary rate and still produce satisfactory water for the after treatment of the ultra-violet rays. The water is exposed for the fraction of a second within an inch of the source of the rays, and this is accomplished by means of various mechanical apparatus, one or two of which are now on the market.

It is our opinion that this treatment of ultra-violet rays is worthy of consideration by consulting and municipal engineers in this country in future installations, and should also be investigated on a commercial basis by engineering colleges.

Andrew F. Macallum, Chairman.
J. Walter Ackerman.
G. A. Roess.

Ohio led the states in the value of her clay products with an output amounting to $34,811,508, or over one-fifth the total production for the United States. Pennsylvania was second, with a production valued at $21,537,221; New Jersey third, with $19,838,533; and Illinois fourth, with $15,210,990. Eight states produced clay products in 1912 to a value exceeding $5,000,000, and 26 states to a value exceeding $1,000,000.

REINFORCED PILE FOUNDATIONS FOR BLAST FURNACES.*

By Armand Baar.

THE question of foundations often plays an important part in iron and steel works, where engineering skill requires to be exercised with special care, in view of the responsibilities which devolve upon the engineer when erecting heavy plant on a poor subsoil. The frequency with which such poor subsoils occur in works is due to three causes: (1) The price of land often compels the utilization of certain areas hitherto undeveloped, owing to their unsuitability for building purposes. (2) The need of a water supply for steam engines often necessitates a works being installed close to a river, which by the gradual shifting of its bed, may have undermined the adjoining areas. (3) Lastly, the production of dump heaps for the embankment of railway junctions require constant filling up with debris either as simple ash-shoots, or by the tipping of slags from blast furnaces into mounds which often attain a height of 65 ft., and upon which it is dangerous to install machinery in motion owing to the lack of stability of the foundations.

In Belgium in particular, as well as in the North of France, and in the Grand Duchy of Luxemburg, a new system of foundations known as Franki piles is being employed with considerable success in most of the big works. The principle is, briefly, as follows: A conical perforator armed with a hard steel point is driven into the ground by the help of a pile-driver. This perforator carries with it telescopic tubes which serve as tubbing, and have an average diameter of 2 ft. The perforator thus passes through the hardest ground. An instance may be adduced at Ougrée, where the process has been applied on a slag tip 30 ft. in height, and consisting entirely of slag blocks from a basic steel works, of a size extending to about 80 cu. ft. each. Reference may also be made to instances where the ground has been exceedingly soft and highly water-bearing, as at the Courrières Collieries, where the soil consists of peat and water-bearing sands, and where three bridges have been erected. The object of the system is to bore through the overlying ground until a solid foundation of clay or gravel is encountered.

The perforator is then withdrawn and replaced by concrete, which is rammed down by degrees as the tubes (commencing with the lowest) are withdrawn. By means of the ram the concrete is compressed so as to press against the sides of the bore-hole and to consolidate them, until ultimately the bottom is enlarged and a cone obtained, pressing against the side walls of the cavity.

Amongst applications of this process which may be referred to, one of the most interesting was the strengthening of No. 2 blast furnace at the Esch-sur-Alzette works of the Société des Aciéries Réunies de Burbach-Eich-Dudelange in the Grand Duchy of Luxemburg, and its supercession by a furnace of twice the size.

The masonry batter of this furnace rested on gravel 14 yards below the level of the soil, and the ground had been packed up entirely with goaf of an inferior description. Several break-outs from the furnace had, however, penetrated the packing at different times, and it was feared that lumps of metal might be encountered at several points, which actually happened later.

Forty-one piles were driven, each calculated to sustain a load of 70 tons, and in order that the concrete arch, which had to rest simultaneously on the batter and on the pile itself, should distribute its load uniformly, there was placed, above the masonry, a layer of granulated crystalline slag 4 in. thick, mixed with a little cement, so that if, under pressure, the fresh cement should spread, any further increase in the load would bear upon the crystalline slag and further compress the latter by crushing it, after which the injection of water at the bottom would finally mortar the arch to the masonry, by the action of the cement originally introduced as an addition, with the dust of the powdered slag.

The furnace is in full working order, and the method of construction has been perfectly successful, and shows no sign of settlement.

Another interesting application of Franki piles was made in erecting the rolling mills of the Ougrée Marihaye Company. On a tip composed entirely of slag blocks to a height of 30 ft., resting on 15 ft. of bad subsoil, these mills work 35 ft. above the level of the Meuse gravels. The whole plant, including mills, buildings, gas producers, etc., rests on 180 piles, which were driven through this thick layer of slag. Not a single pile had to be left unfinished during boring, and the whole of the work proceeded without interruption.

The Athus-Grivegnée Company has erected a similar plant at Athus, under analogous conditions, but in this instance the piles are only 30 ft. long. Franki piles have also been most satisfactorily employed as foundations for gas engines at the works of the Société Métallurgique de la Basse Loire, at Trignac (St. Nazaire), at the Aciéries de Micheville in Meurthe-et-Moselle, and at the works of the Société des Hauts Fourneaux de la Chiers at Longwy.

It may also be interesting to add that before constructing the foundations of the Ougrée Marihaye rolling mill plant, the company carried out a test on a Franki pile, which was loaded with a charge of 473 tons.

Discussion.—Mr. Andrew Lamberton, Coatbridge, said that the subject was a very interesting one, but he would like the author to give some additional information with regard to the stiffening up of insecure foundations. It was largely a question of cost. He would like to know what was the time taken to put down a pile of about 3 ft. in diameter through 30 ft. of solid basic slag, and what was the cost; also whether there was any difficulty in withdrawing the tubes, which he would expect to find was the case. The paper contained a cross-section of a pile which had been put down, and it was obvious that the tubing was much less in diameter than what the slag pile was depicted as being, that diameter being reached by filling in concrete in the metal tube and hammering it down till it expanded. There seemed to be some difficulty about that, and in getting a section resembling that shown in the illustration. A good deal appeared to depend upon the porosity of the material and the number of fissures present, while the concrete might get out of the true line of the pile. The method described was certainly ingenious, and if it could be done satisfactorily and was commercially sound the author would have accomplished a smart thing in engineering.

M. Baar, in reply, said that the cost of driving was about $10.00 per yard in hard soil and about $5.00 in easy soil. With regard to the time element, they had put down one pile per day of 12 hours to a depth of 49 ft., and in the case of one big contract a thousand piles had been put down.

Later, by letter, he replied in respect to a suggestion of simply consolidating the ground by an injection of

* From a paper read before the September, 1913, Convention of the Iron and Steel Institute, Brussels.

cement, as follows: When the tip consists simply of slag blocks from blast furnaces, the space left between the blocks being pretty large, the work would require the injection of a vast amount of cement, and the operation could not be conducted easily over a certain height. In most cases, however, the tip is formed of debris of all kinds, especially clay and earth, and in this the injection of cement is attended with bad results. The Franki pile gives full security, because it not only passes through the tip, but also through the bad soil which lies underneath it, and rests on a strong foundation of clay or gravel.

Mr. Lamberton asked further whether it would be possible to drive tubes having a diameter of 1 yard into a tip of 10 yards in height; in the affirmative, what was the time required for the operation and the cost of the pile. We have driven 180 Franki piles, at the Société d'Ougrée-Marihaye, into a tip composed entirely of slag blocks to a height of 30 ft. resting on 15 ft. of bad soil. The work, therefore, was more difficult than the one alluded to by Mr. Lamberton, and, nevertheless, we regularly made one pile a day with each pile-driver. That the first tube at the ground level had a diameter of 1 yard and a height of $1\frac{1}{2}$ yards was due to the necessity of first digging a hole of such dimensions as to enable the use of tube lengths suitable for the required depth. The upper tube had a diameter of 24 in., the mean one a diameter of 20 in., and the lower one a diameter of 16 in. In a strong ground, free from water, it is not necessary to work with tubes of great diameter, the concrete spreading easily against the walls of the cavity, and agglomerating round the stony materials forming the pile, and increasing the diameter of the latter.

As to the price of the Franki piles, it is generally of $5.00 per yard, for piles driven into an easy, soft, or marshy soil. But in tips of slag blocks, where piling is slow and difficult, the price rises up to $10.00 per yard. From the economical point of view, the following may be regarded as a typical instance:—

One thousand Franki piles are now being driven on account of the Vilorde Coke-Ovens Company. Each pile contains 123.5 cu. ft. of concrete. The total volume of the concrete thus poured in a relatively small area is about 45,800 cu. yds. If reinforced concrete piles made in advance had been used, the cost of the foundations would have been three times as high as that paid by the Vilvorde Coke-Ovens Company to the Frankignoul Company, supposing that, in order to obtain the same compression of the soil, an equal volume of concrete had been driven in the shape of such ready-made piles.

ELECTRICAL POWER IN CHICAGO.

Chicago leads the world in the production of electric power. The output of 303 electric-supply undertakings in Great Britain for the year 1911-12 amounted to 1,127,499,742 units, but Chicago by itself has an annual output of over 800,000,000, and expects within a year to turn out a billion. The Chicago Commonwealth Edison Co., generates more current than the local Edison companies of New York, Philadelphia, Brooklyn and Boston combined. The Eastern companies, however, do not supply power for local transportation, while the Chicago company does. The latter operates the largest single electric-power-generating plant in the world and its price for its product is said to be lower than that of any other electric power-vending company in the world.

TREATMENT OF WORN OUT AND RAVELLED MACADAM SURFACES.*

By Col. Edmund A. Stevens,
State Highway Commissioner of New Jersey.

BEFORE discussing the cure it is well to define the trouble, and to analyze its causes. The word Ravelling is used rather loosely. For my purpose I shall consider it as the loosening of the bond of a road surface until the macadam stone lies loose and free on the road. By macadam stone, I mean, not the small stone used to fill voids and give a smooth finish to the surface, but the stone that constitutes the body of the road's surface. In macadam work this stone when compressed to its final form occupies about 60 per cent. of the volume of the road surface. The 40 per cent. of voids is filled in varying proportions with surface stone, screenings, stone dust, sand, earthy materials and any chemical binder used to "hold the road." The mixture of fine stone, sand and earth filling the voids has no appreciable tensile strength. Its duty is to wedge the macadam stone in place and prevent internal movement. Such a structure is called on to carry loads, to receive and absorb propelling thrusts. The road should be of sufficient depth to transfer the stresses thus imposed to the sub-base without serious internal movement and at unit pressures less than the resisting power of the soil. It is thus subjected to vertical and horizontal forces that contribute largely to ravelling.

Let us briefly consider these.

A draft horse weighing 1,200 lbs. will have all his weight at one time on two feet. He will exert, say, one horse-power at a speed of 4 miles. The vertical force at the foot is 600 lbs., the horizontal $\frac{23{,}000}{2 \times 4 \times 88} = 47$ lbs. These forces are or may well be concentrated on a toe calk two inches in width; the resultant force slightly exceeding 300 lbs. per linear inch.

A motor truck, loaded, 16,000 lbs. and exerting at the wheel rims, say, 30 horse-power at 10 miles an hour, will, with 60 per cent. of load on rear axle, exert a vertical force of 4,800 lbs. and a horizontal of 562.5 lbs. at each rear rim, the resultant being about 800 lbs. per lineal inch for six-inch tire.

For a pleasure car weighing 4,000 lbs. with 60 per cent. of weight on rear axle and exerting 40 horse-power at the wheel rims with a speed of 35 miles, the vertical force at each wheel is 1,200 and the horizontal 214. The resultant is about 400 per linear inch for a bearing width of 3 inches.

At curves with high-speed cars, the horizontal force is considerably increased, for it is impossible to so "bank" a curve as to suit the speed of all classes of traffic.

In the case of wheels transmitting vertical loads only, observation indicates but little dust raising from a road not overlaid with loose dust. Such a wheel will at the point of mathematical tangency have no velocity relative to the road; a vertical velocity is imparted to it, and as any section leaves the surface it will raise with it any of the lighter particles that are loose and may come into contact with it. At the driving wheel there is a slight slip which in addition to lifting will throw particles backwards.

* Read at American Road Congress, held at Detroit, Mich., September 29th to October 4th, 1913.

These are the forces tearing at the road surface. In some cases they are more than the road can stand. The horse's calk acts somewhat like a chisel. It will pry out the binding material between the stones as well as the latter themselves when the bond is weakened. The driving wheels of motor vehicles push or suck any material thus loosened out of place. The binder loses weight as it parts with moisture; besides this, without moisture it also loses, not only its property of recementing itself under pressure, but to a great extent, its binding power as well. The real work of transmitting the stresses due to traffic must be borne by the stone. These are merely held in place by the binder. The latter is gouged out by the horse, drawn or pushed out by the automobile tire, blown away by the wind, or washed off by the rain, and a loosening of the upper stone results.

Even on a well consolidated road climate stresses impose a heavy duty. If, however, there be voids the risk of failure increases. Voids may be due to deficient rolling or to the rise of too much clay in the earthy binder. Lumps of this material will bridge the space between stones even under hard rolling. The bridge will break down eventually either from pressure or moisture or a combination of them. A void forms where the bridge was and continues rising until near the surface, when ravelling results. The same may be true in the cases of too light rolling.

When bituminous material is used as binder it is liable to disintegration from weathering, from overheating, or from admixture of earthy materials.

An ordinary water-bound macadam may lose material by wear up to a thickness of about a half an inch a year without being overloaded. The thickness that can thus be lost will vary with conditions, one of which probably is the ratio of the maximum wheel load to the total tonnage borne by the road.

Whatever the rate of waste, it must be replaced if the road is to be maintained.

To summarize the foregoing:—

Roads ravel from:

1. Improper construction.
2. Overload.
3. Neglect.

In all cases these affect the binder.

Poor workmanship in construction can only be cured by remedying the original defects. These generally show themselves by small local depressions in the surface from which ravelling spreads, in certain cases at an almost incredible speed. In bituminous surface faulty material and thin spots generally show up clearly. In both cases the only remedy is to rebuild the work properly, if necessary, from the sub-base up. This is not strictly repair work.

In considering the effect of overloading and neglect it must be borne in mind that any given type of construction may be so maintained as to vastly increase its carrying capacity. The problem is largely one of economics and administration. As an illustration, assume in two cases the same foundation—let one road have a water-bound macadam surface dressed with a heavy bitumen forming a sheet about ½ in. in thickness and the other a bituminous concrete (mixed method) surface of, say, two inches. The former will cost about 40 cents for stone and 15 cents for dressing, or 55 cents per square yard, and the latter about $1.00 (both exclusive of the foundation). With proper care the lighter surface will last about three years under fairly heavy traffic, the heavier one an unknown period, but let us assume twelve years. The total yearly charges against the two may then be stated about as follows:—

	Cents.
Dressed Macadam:	
Interest on cost, 55 cents at 4 per cent...	2.2
Depreciation, 1-3 of 15 cents.....	5.
Labor (patrol system)	1.9
Materials—Stone, ⅜ cu. ft. at 9 cents...	3.4
Bitumen, ⅛ gallon at 12 cents	1.5
Total	14
Bituminous Concrete:	
Interest on cost, $1.00 at 4 per cent.....	4.
Depreciation, $1.00/12	8.3
Labor	.9
Material	.8
Total	14

The fixed charges are 7.2 cents against 12.3 cents. The operating charges, 6.8 cents against 1.7 cents.

I do not claim that these figures are more than illustrations of the principle involved. They show a great saving in operating charges, those that show up in the yearly tax bill. The fixed charges, however, are just as real, and must be met at some date.

For a road with 9,500 square yards per mile the costs as shown in yearly tax charges, where depreciation and interest are not visible, would in this case be,

For the dressed macadam, per mile.... $636.50

For the bituminous concrete 161.50

yet as shown above the real cost of the two roads is the same. This case affects our subject, because the treatment of a raveller road surface must depend on the system of maintenance.

In most communities the great consideration is the next yearly tax bill. If that can be kept down for a period the ultimate economy of such a policy receives but slight attention. It is generally easier to get money for a new road than for repairs. A road requiring a large yearly repair charge is condemned without a hearing. The road calling for heavy interest and depreciation charges may be an equally or even more expensive solution; but the interest charge is not so apparent, and the depreciation charge is not made. This is simply putting off the day of reckoning, which is sure to come. However, the troubles of those in charge ten years hence are usually lightly borne by the officials of to-day.

If we consider the structure of the road surface we can easily see that the 40 per cent. of voids in the macadam stone will be filled somewhat as follows:—

	Per cent.
Surface stone, passing 1-inch ring and caught on ½-inch ring.....	15 to 20
Screenings, passing ½-inch ring....	15 to 10

The other 10 per cent. should be composed of sand and clay.

When dry, the clay is driven off to a greater or less extent as dust, washed away or splashed off as mud. Its place is supplied to some extent by detritus, the result of the wear of the larger and heavier materials. These also blow or wash away and the road loses its bond. If our road is not overloaded we can retain its usefulness by making good its losses, with proper materials in their needed proportion. It is here that the trained road man is most needed. Nothing can replace his experienced judgment.

In the case of a ravelled road, having first determined that the road was well built, we must decide whether the traffic is too great for the type of surface, or whether the failure was due to neglect. If the former, we must resurface with some better type. If the latter, we can repair the old surface.

Resurfacing should always be preceded by scarifying and by bringing the road up to the necessary depth of stone. For water-bound macadam needing greater surface strength, several classes of chemical binder may be used, of which I shall discuss two, bitumen and lignin.

The bitumen may be applied either by penetration or mixing methods. The former is the cheaper, the latter the more trustworthy. Which method is to be used will, after consideration of the care the road will receive, depend on the estimate of the overload, as will also the depth of the bituminous sheet. My own observation leads me to question the wisdom of attempting to get any thickness exceeding one-half inch by penetration methods. It also leads me for this class of work to prefer tar to asphalt. The former material appears less sensitive to injury by dirt and to yield better results in repair work.

The lignin binders are derived from the waste products of wood pulp or tannin manufacture. They are cements, being also used to bind core sand in foundry work and impart a tensile strength to the binding materials. They will not act on materials soaked in the so-called road oils. The action of some of these materials on slag and red shale is quite remarkable. They are slightly soluble in water, and will, therefore, need renewal. Their application, however, is easy and inexpensive, and the effect of successive applications seems cumulative, increasing not only the depth of penetration, but the strength of the bond. The waterproofing of lignin-bound roads with bituminous tops has been carried out in Connecticut, but I am unable to give any facts as to the results.

For water-bound macadam roads that have failed through neglect a thin coat of gravel carrying some earthy matter, or of screenings or coarse sand mixed with earth, will usually cure cases that have not gone too far. In some of the counties of New Jersey it is usual to fill all ruts, depressions, etc., with fine stone, and to give the middle of the road a coat of the same mixed with a little clay. Much of this material is wasted by being thrown off the road by the traffic, and the old ruts almost invariably reappear. This method, however, is very successful in preventing ravelling. It seems a false economy to omit rolling, and wet rolling at that. The same is true of patching holes with anything but macadam-size stone. The roads treated with small stone are yearly losing depth. The moisture for wet rolling is usually bountifully supplied by nature, in the early spring. It can also be had by the use of hygroscopic salts where water is hard to get. Traffic will usually throw off from the road surface enough stone to pay for rolling.

A treatment of clay, without rolling, will often give astonishing results. Such treatment, however, seems only a palliative, not a cure. Roads thus treated become dusty or muddy according to the weather, show a tendency to ravel again, and are hard to properly treat with bitumens. They will, however, take the lignin binders with good results, if the dose of clay has not been excessive, or if the excess is swept off before treatment.

In closing, a word of warning as to the use of the so-called cold oils may not be out of place. Those of the so-called non-asphaltic class, to a greater extent than the so-called light asphaltic oils, seem to act as lubricant on road materials and to foster pot-holes, ravelling, and other failures. It may be possible to properly apply these materials, but if so it is rarely done. It is certain that even slight depressions will cause a deep penetration of the road. The dust-laying qualities of the material thus absorbed are lost, and its lubricating effect given the best possible conditions to get in its pernicious work. Local authorities, and even private individuals, seem to select roads with uneven surfaces as those on which to use these oils.

ELECTRIC WELDING FOR TRACK REPAIRS.

There are many methods by which electric welding can be carried out, one of the most interesting being, perhaps, that of Zerener, which consists of a combination of an electric arc and an electro-magnetic device whereby the arc can be controlled. Two heavy carbon electrodes are used, and the arc which is struck between them is blown to the position in which it is required by means of the magnet. The most simple is the Bernardos process, which consists of drawing an arc directly between a carbon electrode and the metal which is to be treated. The outfit consists merely of a rheostat for controlling the current, a carbon electrode which consists of a hard, solid carbon rod about 4½ ins. in circumference and some 8 ins. or 10 ins. long, fitted with a clamp to take the conductor, and with an insulated handle and shield to protect the operator. There is also the Lorain system, which requires a comparatively costly plant, with generator and hydraulic grips, used principally for making rail joints by welding on splice bars.

An interesting method of building up new metal in the worn parts of tram and other rails by electric welding is now being used, the special feature of the process being that it requires no carbon electrode. The electrode is a rod of specially treated steel, and the arc between it and the rail, according to information made public by the engineer of the firm using it, fuses the electrode and welds it to the steel, building up new metal in the worn or defective places. Current is taken from the trolley wire, and the equipment consists of a light car provided with rheostats for controlling the current and the necessary switch gear. An insulated handle is provided for holding the metal electrode, which is, of course, the positive terminal, the negative being the rail on which the repair is to be carried out. The electrode is placed in momentary contact with the defective portion and withdrawn, an arc being thus formed which carries metal from the positive bar of steel into the faulty place. The action continues as long as the electrode is held in position, and can be stopped at any moment, either by opening a switch or moving the electrode away, so that the arc is broken.

With a galvanometer receiver reflecting a beam of light on a moving photographic strip, H. Abraham, of the Paris Observatory, makes accurate photographic time records of Hertzian waves. With a clock making second marks on the strip, he claims to make measurements to 1-1,000 second, and to estimate 1-40,000 second on the wave charts.

Clay Products Industry in United States.—The magnitude of the clay-working industry of the United States is shown in a chart just issued, compiled by Jefferson Middleton of the United States Geological Survey. This chart shows a total value for 1912 of $172,811,275, which is an increase of $10,575,094 over the figures for 1911. These products include the several varieties of brick, drain, and other tile, and of sewer pipe, terra cotta, pottery, fire brick, and other clay products, the various building bricks representing the greatest value, with a total of $73,425,810. The number of building bricks manufactured was 10,281,114,000.

ELECTRIFICATION OF MOUNT ROYAL TUNNEL.

ANOTHER stage in the construction of the Canadian Northern terminal and tunnel has been reached, with the letting of the contract for the electrification of both. The contract, which involves a sum of half a million dollars, calls for the complete electrification of the tunnel and terminal, seven electric locomotives and about eight cars for the local service being provided, while the system will be such that it can be extended at any time to any part of the service. Yards near the Back River will be opened, giving track facilities for changing the electric locomotives for steam and vice versâ, and within a year from now trains are expected to be running.

In the construction of the tunnel beneath Mount Royal there have been many new features and much to attract the attention of the engineering world. These features have been currently described in previous issues of *The Canadian Engineer*. Readers will also remember the announcement early in June of a world's record in tunneling in connection with the piercing of the mountain. In the electrification another record will be marked. Of all the great railway systems of the world using electricity for the operation of their terminals, there is not one which has not adopted this system only after previously using steam. The Canadian Northern terminal in Montreal, therefore, will be the first to be operated entirely by electricity from the commencement. No steam locomotive-drawn trains will enter the tunnel. Specially constructed electric locomotives will be exchanged for the steam engines at the Back River yards. For the local service between Montreal and the Model City there will be some eight multiple-unit cars of very heavy construction similar to those in use in some of the New York subways.

The contract, which has been let to the Canadian General Electric Co., provides for the installation of the system at a cost of about half a million dollars.

The installation of this electrically operated system will ensure the entire absence of Canadian Northern locomotives in or near the city, none coming closer than the yards near the Back River. On reaching these yards trains approaching Montreal will have their steam locomotives exchanged for electric motive power, which will take them to the terminal station to be opened on Dorchester Street. In the city there will, of course, be no steam engines as the railway enters and leaves only by way of the tunnel.

Progress on the tunnel construction has of late been rapid, despite the very hard rock now being encountered, and it is practically certain that the headings will meet well before the end of the year. There remains but 2,000 feet of rock separating the two headings, and this is being bored at the rate of 200 feet each week. Already a mile of tunnel has been completed, this being a broadening and enlarging of the heading to a height of 22 feet and a width of 30 feet.

In connection with the electrification of this tunnel it might be mentioned that the same company who will supply its electrical equipment also secured the order from the Canadian Pacific Railway for the electrification of the Castlegar branch in the Kootenay Division. Heavy power locomotives are to be used in this case also, and the voltage adopted is 2,400 volts in both.

---

*Canada is one of the three principal mica-producing countries of the world, the others being India and the United States. The average value of the mica produced annually in Canada during the last ten years has been about $185,000.

FELDSPAR.

According to reports in the Economic Minerals and Mining Production of Canada, by J. McLeish, feldspar is employed at the present time almost entirely in the pottery industry (where, in a finely ground form, it is mixed with the clay to act as a flux), or in the enamelling of cooking and similar utensils. Attempts are being made, also, to utilize the mineral as a source of potash, of which it contains as high as 14 per cent.

Feldspar has been mined in Canada since the year 1890, and the present average annual production is 12,000 tons. Practically the whole of the output is exported to the United States, where it is consumed in the New Jersey and Ohio potteries. Almost the entire production of Canadian feldspar is derived from the province of Ontario—the principal mines being located in the county of Frotenac, about twenty miles north of the town of Kingston on the St. Lawrence River. A few small deposits, also, have been worked in the Parry Sound district, in the vicinity of the Muskoka lakes. Formerly feldspar was mined to some extent, also, in the province of Quebec—the deposits being located in Ottawa county. No development of these properties has taken place during recent years the distance from the United States factories rendering mining unprofitable. One mine in this region yields a remarkably pure white feldspar, which is in demand for the manufacture of artificial teeth.

Veins or dykes of pegmatite (a rock having feldspar as its main constituent) are of common occurrence throughout large areas in both Ontario and Quebec, and have in some instances been mined for the mica which they often carry. These deposits vary in width from mere stringers of a few inches to massive bodies of over a hundred feet. Such deposits, while, at the present time, often too remotely situated, or containing too many impurities in the way of accessory minerals to allow of the feldspar being employed for pottery purposes without considerable expensive cleaning, constitute large reserves of the mineral, which may ultimately prove of value as a source of potash or for other purposes.

The addition of trass slightly retards the setting of mortars and concretes, increases their resistance to water, greatly increases the strength of mixtures gauged with lime-water, and decreases the detrimental effect of soap solution. Lime-water increases the strength of trass mortars, but has no influence on the strength and water-tightness of mixtures which do not contain trass. Soap solution renders mortars and concretes water-tight and diminishes the hardening of mortars without trass, which weakening effect is counteracted by the addition of trass .

Scientific methods are giving great exactness to processes for hardening valuable tools and drills. Uniform and easily controlled heating is necessary, and this is easily obtainable with the electric furnace. A special form recommended has a crucible 8 ins. square and 12 ins. deep, lined with firebrick surrounded by heat-insulating material in a sheet-iron case. This crucible contains the heating bath, the temperature of which is regulated by a transformer for varying the voltage, and a pyrometer gives quick and accurate determinations of the degree reached. The bath varies with the temperature required. A mixture of barium chloride and potassium chloride is used for hardening carbon steel, at 750 deg. to 1,000 deg. C., the proportion of barium chloride increasing with rise in temperature, and this salt alone being advised for high-speed steel, at temperatures up to 1,300 deg. The crust of salt which adheres to the tool, preventing oxidation, falls off in the cooling liquid.

COAST TO COAST.

Niagara Falls, Ont.—The Ontario Power Company is seeking permission from the Queen Victoria Niagara Falls Park Commission to construct a third pipe line from its gate house on the upper river to its power house below the Horseshoe Falls. At present the company have two pipe lines, one of steel, which has been in use since the power house was put in operation, the other of concrete which was installed two years ago. Through these the company is diverting about 8,000 cubic feet of water per second, which is approximately two-thirds the amount of water permitted to its use under the provisions of the international treaty. By this amount of water, twelve units in the power house are operated, each generating 1,400 electrical horsepower. Providing the water is increased, the company propose enlarging their battery to 14 units; and where now only 130,000 horsepower can be developed by the plant, the company will be able to transmit 196,000 horsepower. The patents of R. O. Blainey, who assisted in the construction of the second pipe line, for a continuous concrete pipe are being investigated by power company officials, and should they be approved, it is possible that a monolithic pipe, which is the first of its kind in the world, will be constructed.

Hamilton, Ont.—An industry has been secured for Hamilton which gives much promise towards the further expansion of the city and the location of more industries at this centre. It is announced that the Hamilton By-Product Coke Ovens, Limited, has been incorporated at a capitalization of 1,000,000 dollars. The purpose of the company, primarily, is to manufacture coke for smelting and foundry usage in Hamilton and Central Ontario, and also for domestic and minor industrial supply. In addition, the plant will provide a permanent supply of gas of high candlepower and of a very high heat value, which will be of great value in the event of the depletion of the natural gas wells of Haldimand county and its vicinity.

Halifax, N.S.—Considerable discussion is being given to the question of ornamental street lighting in Halifax. The City Improvement League have been bestowing their efforts to bring to the citizens the best opinion of experts on the subject. Recently, at the request of this body, Mr. F. H. Winckly, of Lynn, Mass., an authority on street illumination, gave an address in which he sketched its history from the age of streets clothed in darkness to the present of the "Great White Way."

Montreal, Que.—A new work, which is occupying the attention of the Harbor commissioners at present, is the wharf being constructed by the Canada Cement Company at Point aux Trembles. It is of cement, and will be, when completed, about 600 feet in length.

Montreal, Que.—The end of this season will see unfinished little, if any, of the program of harbor works published at its beginning. The additions to grain elevator No. I., have already attained a height of about 135 feet from the level of the wharf. Concrete bins, 52 in number, have been constructed with a capacity in totum of over a million bushels, the largest to hold upwards of 21,000 bushels, the smaller, from 3,000 to 8,000 bushels.

Port Colborne, Ont.—Inaugural ceremonies, attended the opening of the new plant of the Canadian Furnace Company, Limited, at Port Colborne. It is the most modern of its kind in the world, and has been constructed at a cost of seven million dollars. Miss Theresa Yates, daughter of the vice-president of the Buffalo Union Furnace Company, owners of the Port Colborne plant, applied the torch that lighted the furnace; and William Weller, Esq., Superintendent of Canals for the Dominion of Canada, sounded the whistle of the plant for the first time. The signal was thus given for an answering medley of shrieks from all craft in the town harbor, from the company's locomotives, and from neighbouring factories. Mr. Frederic Nichols of Toronto, president of the Canadian General Electric Company and Mr. R. S. Logan, vice-president of the Grand Trunk Company, responded to toasts; while Mr. E. H. Butler of Buffalo, commended highly the Canadian enterprise and spirit of co-operation which, he declared, is responsible for Canada's rapid development, commercially, agriculturally, and industrially.

Toronto, Ont.—Commendable progress is being made on the power transmission equipment for Eastern Ontario by the Hydro-Electric Power Commission. Plans are deposited with the department of public works for approval of an arrangement for towers and cables across the St. Lawrence River at Morrisburg. The Commission has secured an option of 1,500 horsepower from the New York and Ontario Power Company at Waddington, N.Y., and are awaiting the partial completion of the plant to import a portion of this power to Canada. Until the new plant is entirely complete, the heavy exportation cannot commence. The Canadian line from Morrisburg to Prescott is finished, and it is expected that the line from Winchesteville, Chesterville, and Russell, will be in readiness in a short time.

Regina, Sask.—The Regina Municipal Street Railway showed a deficit of $42,868.11 for the eight months ending August 31, after provision for capital charges had been made.

Ottawa, Ont.—The greatest area under wireless contract in the world, a distance of 2,000 miles will soon be completed in Canada. With the completion of stations at Port Burwell, Toronto and Kingston, a complete chain will extend from Port Arthur, through the Great Lakes, and along the St. Lawrence to Cape Race.

Vancouver, B.C.—The wiring inspector of Burnaby, Mr. Burns, has been experimenting for some time on a power switchboard for the municipal service. It is not yet complete, but is in use and is found to act very successfully. The features of the board are the means of taking the electric light current, transforming it and charging the storage batteries used in the phone service. Another thing that is said not to be in general use in telephone work except in large installations, is the construction of an artificial line, by which by the principle of the Wheatstone Bridge method of testing wires, it will be possible, in the event of trouble occurring on any line, to measure its exact distance from the municipal hall, and also to determine the nature of the trouble, thereby saving time and unnecessary work. Another outstanding feature of the board is a bank of switches the purpose of which is the coupling together of the storage batteries; and any particular cell may, by means of the switches, be disconnected from the service for charging, repair, or any other purpose. It is also the intention of putting on the board, all repeating coils, induction coils, condensers and other apparatus, so that they will be under observation at all times. The keener protective devices are also on the board, their purpose being to take the first effect of any abnormal currents that come over the system. Coupling and disconnecting switches, by which any particular line may be disconnected for repairing, testing, or other purpose, are also on the board. The use of the board is expected to obviate a great amount of trouble in connection with the working of the municipal telephone system.

Fort William, Ont.—It is probably not generally known that the grain storage elevator capacity of Fort William-Port Arthur has now reached the enormous amount of 41,035,000

bushels, and ranks second among the cities of the world as a grain storing centre, exceeded only by Chicago, Ill., with elevator capacity of 45,300,000. With the additional elevators now under construction and others projected at the Canadian head of the Lakes, it will only be a matter of 12 or 18 months before Fort William-Port Arthur will have the distinction of being the largest elevator storage centre in the world.

Rainy Lake, Ont.—Midway between Port Arthur and Winnipeg, the C.N.R. has been effecting an engineering achievement of no ordinary value. A bridge of solid rock, a great double track causeway of granite almost three miles long and costing approximately one million dollars per mile, will span the Rainy Lake in a not distant future. The contracts were let early in the summer of 1910 and preparations for the work were begun; yet the great task has been conducted so quietly that few people in Canada have been aware of the magnificent and unordinary construction.

Kingston, Ont.—Now that the Hon. Adam Beck is free to further the distribution of power throughout eastern Ontario, Kingston is feeling the cry of need of several of its industries for cheap power to insure their future expansion, and is agitating that arrangements for supply be concluded with the Hydro-Electric Commission.

St. Catharines, Ont.—St. Catharines is struggling with natural barriers towards progress similar to those encountered by Toronto in its primal growth. The Welland Canal and some creeks running through the west and south are preventing expansion in somewhat the same manner as did Garrison Creek and the Rosedale and Don ravines in Toronto. Toronto has now her Riverdale and Rosedale bridges, but St. Catharines is still struggling with her bridge problems.

Edmonton, Alta.—Mr. A. T. Fraser, District Engineer for the C.N.R., is of the opinion that steel on the Canadian Northern main line should reach the summit at the boundary of Alberta and British Columbia about the end of October. On the Brazean branch, construction is very difficult, owing to the great amount of trestling to be done. Steel is within 30 miles of the Brazean coal fields, but it will be December before the line is connected with the colleries. The Peace River branch west of the McLeod River is being graded.

Telkwa, B.C.—Men who went south from here over a week ago to investigate the discovery of placer gold, reported by Price, Ecksley and Pearson, have returned to Telkwa satisfied with the richness of the field. The men who have returned, Colin Munro, Ira McLean and King, state that in no instance where panning operations have been carried on by men on the ground has a single barren pan been found. All showed coarse gold in varying quantities. The new find is on Sibbola Creek, one of the tributories of Tahtsa River, about 110 miles in a south-easterly direction from Telkwa, and about 50 miles from the headwaters of Kemano River, which empties into Gardner Channel. The men who have gone in from here have taken the Morrice River trail. It is hardly necessary to state that the stampede is on in full blast in this locality. In fact, construction work on the G.T.P. may be seriously impeded, as five thousand men are now employed within a radius of 125 miles of the new find. The field can be reached from the outside by boat up Gardner's Channel, thence up the Kemano River, but there is a most difficult country to traverse for over 50 miles. Outside expeditions would have to carry all supplies from the point of embarking. The lack of provisions for men in the field is causing not a little anxiety here, as every pack horse is on the trail coming out.

Montreal, Que.—Many prominent officials of the C.P.R. and Dominion Bridge Companies were present when a made-to-order steel bridge, weighing 2,600,000 pounds was swung across a 270-foot gap in one hour and 25 minutes, a feat accomplished by the Dominion Bridge Co., when placing the third of the four great spans, each 400 feet in length, of the Lachine bridge. The Gazette says in regard to this piece of bridge engineering:—"The admirable manner in which all these great spans have been raised to position, while the regular traffic continued, marks a triumph of engineering. Indeed, the whole double-tracking of the bridge has been accomplished while every train ran on schedule time."

Brighton, Ont.—Water was turned on last week in the new system of supply that has just been completed by J. G. Mill, contractor, Toronto. The water, obtained from Spring Valley, is very pure. The springs have a daily capacity of 700,000 gallons. The water is distributed by gravity, having a two hundred foot head two miles from town. Consulting engineer, T. Aird Murray, Toronto, made a test of the system, which showed 86 pounds pressure on the main street with 100 pounds as the best, and 70 pounds as the worst, pressure throughout the entire town. A reservoir has been constructed in Spring Valley providing storage sufficient to supply six lines of fire hose continuously for twenty-four hours, as well as to accommodate the town's domestic requirements. Brighton, which has a population of 1,600, has not previously had a public water supply.

Vancouver, B.C.—The directors of the Burrard Inlet Tunnel and Bridge Company have decided not to take any action with regard to the Second Narrows bridge project until a definite reply as to the Provincial Government's intentions has been received. The provincial authorities have been asked by the bridge company to assume control of the scheme for spanning Burrard Inlet, and an answer is expected from the British Columbia government within a month when the premier shall have returned from England. Concerning the subsidies sought by the company from the Dominion Government, rumors at Ottawa that the Second Narrows bridge project had been abandoned, have delayed the efforts of the company's agents at the capital; but the president and secretary have denied the reports, and have explained that the company has asked the province to assume control of the enterprise.

Victoria, B.C.—The growth in the establishment of private wireless stations by commercial firms throughout British Columbia has been commented upon by Mr. E. J. Haughton, district superintendent of the Dominion Radio-Telegraph service. In addition to five private installations in Vancouver and twelve in Victoria, which are, for the most part, used by students engaged in the scientific study of radio-telegraphy, there is one firm operating its own plant and sending all its messages to the nearest Government station. The Canadian Explosives Company, on Bowen Island, keeps an operator on duty during working hours, while a high power plant at Cousins Inlet, operated by the Cousins Inlet Pulp Company, transmitted messages to the Government station at Triangle Island until recently. This equipment was of five kilowatt power, owing to the fact that the factory was surrounded by hills, which interfere with wave transmission. Plants have also been proposed for the B.C. Fisheries Company on Queen Charlotte Islands and the Powell River Pulp Company, which, if put into operation, would transmit messages with Alert Bay and Cape Lazo stations respectively. In addition to these wireless plants, a telephone line is now in operation between Suquash Mines and the Government station at Alert Bay, while a second line to transmit telegraph and telephone messages is now under construction between Masset and Dead Tree Point.

Guelph, Ont.—The Ontario Municipal Electric Union carried unanimously the following resolution by the meeting of its representative held recently in the Guelph city hall:—

"In view of the comprehensive scheme outlined by the Dominion Government for the creation and improving of waterways in connection with the St. Lawrence River, Welland Canal, French River, Sault Ste. Marie, Trent, Ottawa and others involving the large expenditure of public money, and in view of the extensive developments which are possible in consequence thereof, also in view of the power requirements of the province, be it resolved that this association request the Dominion Government to put such water powers under the jurisdiction of the Hydro-Electric Power Commission of Ontario, to be developed by them for the use of the municipalities of the province for the benefit of the people." This step was taken to forestall any action on the part of the Government to hand over the control of such a valuable asset to a private corporation.

Spokane, Wash.—The Pacific Logging Congress, held at Spokane, in the latter part of September, announced that the association will make an endowment of $600,000 for instruction in logging engineering in five state universities and in a university in British Columbia.

Montreal, Que.—This year the city of Montreal has carried out a scheme of work and repair on its pavements and sidewalks unprecedented in extent and thoroughness. Mr. G. B. Garneau, superintendent of repairs, gave the following report to the city's board of control:—"In the three divisions of the city, 54,500 square yards of asphalt and 24,000 yards of granite and scoria blocks, a total of 78,880 yards, were repaired this year. In the same three divisions, 13,000 yards of cement sidewalks, 13,000 yards of asphalt sidewalks, and 13,500 yards of stone flag sidewalks were repaired. In addition must be counted repairs to cuts in the pavement. In the eastern division the following cuts were patched up:—5,250 yards of asphalt and 200 yards of granite and scoria block pavements; 625 yards of asphalt, and 150 yards of cement sidewalks."

PERSONAL.

JORO NAGATO, mechanical engineer, is in Canada as a representative of the Japanese Government, to study recent discoveries and developments in mechanical constructions. All the larger cities of the Dominion will be visited.

F. J. HERLIHY has been appointed supervising engineer of the Montreal aqueduct. Mr. Herlihy comes from Great Falls, Mont., where he was in charge of bridge and building construction for the Great Falls-Lewiston division of the Milwaukee line.

MR. W. B. GAIR, director of the Great Central Railway, England, has reached Canada after an extended trip over several of the important American roads. Mr. Gair is accompanied by several engineers, their object being the study of transportation methods in America. They will travel for some distance over the G.T.R. and C.P.R. to further their researches in respect to the Canadian procedure in the handling of frieght and of passengers.

GUY H. MORTON, B.A.Sc., manager of the Calgary office of the Canadian Westinghouse Company, has been appointed lecturer in electrotechnics by the technical education committee of the Calgary Board of Education. Mr. Morton is a graduate of four years' standing of the University of Toronto. CARL STERNBERG, a graduate in electrical engineering, of the University of Minnesota, is in charge of laboratory work.

A. D. CREER, M.Can.Soc. C.E., A.M.I.C.E., who has been in charge of the investigations and reports of the greater Vancouver sewerage scheme, with R. S. Lea of Montreal as consulting engineer, is now engineer to the recently-formed Burrard Peninsula Joint Sewerage Board. Mr. Creer has specialized in hydraulic work and previous to his coming to this country, some three years ago, he was for 13 years on the staff of the late James Munsergh, F.R.S., past president Inst. C.E.

OBITUARY.

A. L. ADAMS, a prominent engineer of San Francisco, Cal., died at his home a few weeks ago. Mr. Adams was well known in Victoria, B.C., where he made several reports in connection with the city's waterworks system.

THE REGINA ENGINEERING SOCIETY.

The first meeting for the season of the Regina Engineering Society, took the form of a banquet at the Hotel Metropole, Regina. The speakers included Lieut.-Gov. Brown, Hon. J. A. Calder, Mayor Martin, J. F. Bole, A. J. McPherson, R. O. Wynne-Roberts, A. P. Linton, L. S. Cockburn and O. W. Smith.

THE CANADIAN RAILWAY CLUB.

The October meeting of the Canadian Railway Club will be held at the Windsor Hotel, Montreal, October 14th. Mr. R. F. Uniacke, Bridge Engineer, National Transcontinental Railway, will deliver an illustrated lecture bearing upon engineering problems encountered in the construction of the N.T.R.

COMING MEETINGS.

AMERICAN SOCIETY OF MUNICIPAL IMPROVEMENTS.—Twentieth annual meeting to be held in Wilmington, Del., October 7th to 10th. Secretary, A. Prescott Folwell, 15 Union Square, New York.

RAILWAY SIGNAL ASSOCIATION.—Annual meeting will be held at Nashville, Tenn., October 14th to 16th. Secretary, C. C. Rosenberg, Times Building, Bethlehem, Penn.

NATIONAL SOCIETY FOR PROMOTION OF INDUSTRIAL EDUCATION.—Annual convention to be held at Grand Rapids, Mich., October 19th to 25th. Secretary, C. A. Prosser, 105 E. 22nd Street, New York City.

AMERICAN MINING CONGRESS.—Annual convention will be held at Philadelphia, Pa., October 20th to 25th. Secretary, J. Callbreath, Majestic Building, Denver, Colo.

AMERICAN RAILWAY BRIDGE AND BUILDING ASSOCIATION.—Annual convention will be held at Montreal, Que., October 21st to 23rd. Secretary, C. A. Lichty, 319 N. Waller Avenue, Chicago, Ill.

UNITED STATES GOOD ROADS ASSOCIATION.—Convention will be held at St. Louis, Mo., November 10th to 15th. Secretary, J. A. Rountree, L021 Brown-Marx Building, Birmingham, Ala.

AMERICAN ROAD BUILDERS' ASSOCIATION.—Tenth Annual Convention to be held in First Regiment Armory Building, Philadelphia, Pa., December 9th to 12th. Secretary, E. L. Powers, 150 Nassau Street, New York, N.Y.

AMERICAN CONCRETE INSTITUTE.—Tenth Annual Convention to be held in Chicago, February 16th to 20th, 1914. Secretary, E. E. Krauss, Harrison Building, Philadelphia, Pa.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for small fee.

20385—September 22—Authorizing C.P.R. to construct a switching lead across Lots 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26 and 27 northerly of Vine St., Toronto, Ont.

20386—September 23—Authorizing C.P.R. to operate its trains over seventeen (17) bridges, Lake Superior Div.

20387—September 22—Extending, until November 30th, 1913, time within which C.P.R. install gates at Osler Ave., North Toronto; pending installation, crossing be protected by day and night watchmen employed and paid by railway company.

20388—September 22—Authorizing C.P.R. to construct spurs for Dominion Bridge Co., Limited, on Saskatchewan Ave., Winnipeg, Man., subject to and upon certain conditions.

20389—September 22—Authorizing C.P.R. to construct road diversion in Sec. 15-18-15, W. 2 M., said road diversion to cross proposed double tracks of company's main line at Station 877, Moose Jaw Subdivision, Sask.

20390—September 24—Authorizing C.P.R. to open for traffic portion of new second track from Iberville Jct., to Iberville Station, mileage 18.7 to mileage 19.2, Quebec.

20391—September 23—Approving and authorizing clearances, as shown on C.P.R. plans, of new train shed at Windsor St., in city of Montreal, Que.

20392—September 22—Authorizing Dominion Atlantic Ry. Co., to construct North Mountain Ry. Branch across Burgess Road, Grafton Road and Chute Road, between Centreville and Weston, N.S.; and rescinding authority granted under Order No. 16582, dated May 22nd, 1912, to cross said road.

20393—September 23—Amending Order No. 20075, dated August 15th, 1913, by adding following words—namely, "the said crossing to be used for construction purposes only and not for the operation of trains after the road is opened for traffic."

20394—September 23—Approving, subject to certain conditions, plan dated September 18th, 1913, showing proposed changes in Algoma Steel Corporation, Limited's power canal at Sault Ste. Marie, where it crosses bridge of C.P.R., at mileage 181.49, Lake Superior Div., Algoma Subdivision.

20395—September 24—Authorizing Lake Erie and Northern Ry. Co., to use, pending installation of interlocking plant required under Order No. 19248, dated June 4th, 1913, the crossing of Grand Valley Ry. at Station 1059.06, for construction purposes only; applicant's trains and cars of Grand Valley Ry. to be flagged over crossing by signalmen provided at cost of applicant company.

20396—September 24—Authorizing C.P.R. to open for traffic portion of its Estevan North West Branch from Estevan, mileage 0.00 to Neptune, near mileage 54.0; provided speed of trains over said portion of railway be limited to a rate not exceeding twenty (20) miles an hour.

20397—September 22—Directing C.P.R. cause its Western Official, or officials, to issue a circular to company's employees, similar in terms to Circular No. 34, issued by Eastern Officials of company and applying to eastern lines.

20398—September 24—Authorizing C.P.R. open for traffic portion of its double track between Roberts and Ramsay, mileages 60 to 70.9, Chapleau Subdivision, Lake Superior Div.

20399—September 24—Authorizing Algoma Central and Hudson Bay Ry., to use overhead bridge between Cathcart St. and Wilde Ave., Tagona, in municipality of Steelton, Ontario.

20400—September 23—Approving revised location G.T.P. Ry. Co.'s main line, through Lot 2012-A, mileage 360, east of Prince Rupert, Rge. 5, Coast District, B.C.

20401—September 23—Authorizing G.T.R. to use subway carrying Coxwell Ave., Toronto, Ont., underneath tracks of applicant company.

20402—September 24—Authorizing Board of Highway Commissioners for Sask., at its own expense, to construct highway over G.T.P. Ry., in N.E. ¼ Sec. 18-14-18, W. 2 M.

20403—September 24—Authorizing C.P.R., to construct spur into premises of J. B. Tudhope and R. A. Carman, situated on Lots 31 to 40 inclusive, Block 200; and to change location of siding already constructed for International Harvester Co., of America, in said Block 200, city of, Regina, Sask.

20404—September 24—Approving location C.P.R. stations at Strathmead, N.E. ¼ Sec. 14-22-27, W. 4 M., and at Strangmuir, S.W. ¼ Sec. 23-22-25, W. 4 M., Alberta.

20405—September 24—Approving C.L.O. and W. Ry. plan showing general layout and masonry details at Bridge No. 87.14 over Sidney St., town of Trenton, Ont.

20406—September 24—Authorizing C.N.R., to construct, subject to terms of consent of village of Findlater, branch line to gravel deposit on S.W. ¼ Sec. 22-21-25, W. 2 M., near Findlater, Sask., and cross surveyed road between stations 21.66 and 22.33.

20407—September 23—Directing that Kettle Valley Ry. Co., provide and construct two farm crossings where is crosses farm of M. W. Smith, Beaverdell, B.C., one near Eastern Boundary of his property at station 1422-50, and one near Western Boundary of farm at station 1451-80.

20408—September 24—Permitting N.Y.C. & H.R.R. Co., operating in Canada the O. & N.Y. and the St. Lawrence and Adirondack Rlys., to use on its locomotive engines wire mesh netting with openings 3/16-in. in width and ¾-in. in length, made of wire not less than .135-in. in diameter, in lieu of requirements with respect to wire mesh netting contained in General Order No. 107.

20409—September 24—Authorizing C.P.R. to take certain lands for purposes of completing diversion of Nine Mile Road, in Lots 6 and 7, Con. 9, Tp. South Gower, Co. Grenville, Ont., as provided by Orders Nos. 18958 and 20267, dated respectively April 1st, and September 4th, 1913.

20410—September 25—Authorizing C.P.R. to construct passing track across road allowance between S.W. ¼ Sec. 27, and S.E. ¼ Sec. 28-16-25, W. 2 M., Saskatchewan.

20411—September 23—Directing that within ninety days from date of this Order, C.L.O. & W. Ry. (C.P.R.), and G.T.R. each install an improved type of automatic electric bell at crossing of road allowance between Lots 16 and 17, Con. "A", Tp. Haldimand, Co. Northumberland, Ont. Each company to maintain its own bell.

20412—September 25—Relieving C.P.R. from providing further protection at crossing of highway at west end of platform at Moffatt Station, between Lots 15 and 16, Con. 2, Tp. Nassawagaweya, Co. Halton, Ontario.

20413—September 24—Amending Order No. 18761, dated February 20th, 1913, to provide that C.L.O. & W. (C.P.R.) build only that portion of diversion north of south boundary of its right-of-way; amending Order No. 19381, to provide that C.N.O.R. construct that portion of diversion south of C.L.O. & W. Ry. right-of-way. And that revised plan and profiles of C.N.O.R. dated Toronto, August 13th, 1913, drawing No. 8566, showing road crossing and proposed diversion of public road between Lots 12 and 13, Con. 4, Tp. Scarboro, be approved.

20414—September 25—Establishing delivery limits of Dominion Express Co., in town of Bassano, Alta.

20415—September 24—Rescinding Order No. 20246, dated August 30th, 1913, suspending, for a period of 30 days from date of Order, effective date of advanced rates in Supplement No. 24 to Tariff C.R.C. No. W-1713, filed by C.P.R.

20416—September 25—Authorizing Algoma Central and Hudson Bay Ry. Co., to open for traffic main line from mileage 30.08 (Franz), to mileage 81 (Oba), Ontario.

20417—September 25—Authorizing Algoma Eastern Ry. to open for traffic main line from mileage 60.76, (West River), to mileage 80.49, (Goat Island), Ontario.

20418—September 25—Authorizing C.N.R. to construct across seven (7) highways on Alsask Southeasterly line, Sask.

20419—September 25—Approving proposed revision of grade on C.N.O.R. Montreal-Hawkesbury Line from mileage 46.69 to mileage 48.62 from Hawkesbury, Tp. Cartierville, Co. Jacques Cartier, Que.

20420—September 25—Authorizing G.T.R. to construct siding across Wellington St., city of Berlin, Ont.

20421—September 25—Authorizing G.T.P. Branch Lines Co., to construct spur for International Harvester Co., of Canada, Limited, turning out from its Yorkton Branch in a northerly direction, across Broadway, in Sec. 35-25-4, and Sec. 2-26-4, W. 2 M., town of Yorkton, Sask.

20422—September 25—Approving amended location of station of G.T.P. Ry. at McBride, mileage 1134.2, Lot 5316, Cariboo District, B.C.; and rescinding approval of said station under Item 1 in Order of Board No. 19643, dated June 16th, 1913.

20423—September 25—Granting leave to corporation of city of Ottawa to construct bridge and concrete sewer across lands of C.P.R., comprising Broad St. yard of company, and under company's tracks and rails situate in said yard. Work on C.P.R. property be done under supervision of an Inspector or Engineer appointed by Ry. Co. City indemnify Ry. Co. against any loss or damage it may suffer by reason of construction of said sewer.

20424—September 25—Approving Michigan Central R.R. plan showing bridge No. 27.74 proposed to be constructed over the Alexander Drain, between Comber and Ruscomb, Ontario.

20425—September 25—Approving location C.P.R. station in Lot 17, Con. 7, Tp. Mara, Co. Ontario, Ont., at Schepler, at mileage 51.4 on Fort McNicoll Subdivision, Ontario Div.

20426—September 25—Authorizing G.T.R. to construct siding into premises of S. L. Lambert, town of Welland, Ont.

20427—September 26—Authorizing C.P.R. to construct two tracks of a wye, at Balgonie, Sask., across highway adjoining the southern boundary of company's main line right-of-way in Sec. 3-18-17, W. 2 M.

20428—September 18—Authorizing city of Toronto to reconstruct Gerrard Street Bridge over tracks of C.P., G.T., and C.N.O.R. Cos., and the Toronto Industrial Siding.

20429—September 24—Authorizing Bell Telephone Co., of Canada, to construct, for purpose of operating its telephone service, pole sand wires upon, along, across, or under highway, in city of Montreal, known as De Biencourt St., on north side, from Boulevard Monk to Raxilly St., Emard Ward.

20430—September 27—Approving revised location C.L.O. & W. Ry. (C.P.R.) until Nov. 1st, 1913, to enable Ry. Co., to remove sheds owned by Crossen Car Co., after which date proposed revision be abandoned and Ry. Co., revert to its location approved April 14, 1913. 2. Authorizing C.L.O. & W. Ry. to cross east leg of G.T.R. Co.'s "Y": crossing to be protected by a watchman appointed and maintained by and at the expense of Applicant Company; and 3. C.L.O. & W. Ry. submit new plans for approval, showing land required to be taken from G.T.R.

20431—September 26—Approving revised location G.T.P. Branch Lines Co.'s Brandon Branch in Secs. 4 and 5-12-15, W. 1 M., mileage 0 to mileage 0.46, Dist. Brandon, Man. 2. Authorizing Co. to construct said Brandon Branch, as revised, across Government Road Allowance between Secs. 4 and 5-12-15, W. 1 M. And 3, Authorizing Company to construct and operate junction between its Brandon Branch and G.T.P. Ry. Co.'s main line, in Sec. 4-12-15, W. 1 M., Manitoba.

20432—September 26—Authorizing G.T.P. Branch Lines Co. to carry traffic over portion of Tofield-Calgary Branch from mileage 107.7 to mileage 20.15 (Calgary), subject to following conditions:—1. Crossing of highway at mileage 107.8 be protected by an electric bell, and that, pending installation of said bell, all trains running in either direction be brought to full stop seventy-five feet from crossing and proceed over crossing under control, prepared to stop at any moment. 2. That temporary station or platform be provided on said line, at Calgary, before operating said line, and 3, speed of trains be limited to a rate not exceeding ten miles an hour through thickly settled portions within limits of city of Calgary.

20433—September 26—Authorizing G.T.R. to construct sidings into premises of Otis-Fensom Elevator Co., Limited, Hamilton, Ont.

20434—September 26—Authorizing C.N.O.R. to construct across public road in Lot 7, Con. "A," Tp. Etobicoke, Co. York, Ont.; said public road to be connected with Islington Ave., north of C.N.O.R. tracks.

20435—September 26—Approving location Moncton and Northumberland Strait R. from Richibucto to Buctouche, N.B., a distance of nineteen (19) miles.

20436—September 27—Authorizing C.P.R. to construct Forsyth St. Branch across Montreal Tramways Co. on Davidson St., Montreal, P.Q., mileage 0.42. Provided Mont. Tramways Co. change location of tracks at point of crossing, to provide safe clearance between sides of cars and vertical support of overhead structure; cost to be borne by C.P.R.

20437—September 23—Authorizing Corporation of city of Toronto, to construct viaduct carrying Bloor Street across property of C.P.R., C.N.O.R., and G.T.R., to connect existing highway with Danforth Ave., east of River Don, subject to conditions that piers shown on said plans be moved 45 feet to the east, and providing there be room between river and pier D when so moved to enable C.N.R. to place tracks.

20438—September 24—Extending free collection and delivery area, in town of Walkerville, Ont., prescribed by Order No. 19534, dated June 9th, 1913, by inserting following paragraph between second and third paragraphs of mandatory portion of said Order, namely; also, in St. Luke Road from Edna St. southward to and including plant of Tate Electric Company.

20439—September 26—Authorizing Montreal and Southern Counties Ry., subject to terms and conditions of agreement, to run and operate its trains and cars, with passengers, baggage, express, and other traffic carried thereon, over and upon line of railway of Central Vermont Ry. Co., between Richelieu and Marieville, Que.; and to use Central Vermont Ry. Co.'s passenger and freight stations, station yards, and other facilities at and between said points.

20440—September 27—Authorizing C.P.R. to construct bridge No. 75.6 on Havelock Subdivision, Ont. Division.

20441—September 27—Approving, temporarily, G.T.P. Ry Standard Freight Mileage Tariff, C.R.C. No. 19, incorporating and superseding C.R.C. No. 17 by extension of mileage thereof, to apply between stations in British Columbia, Prince Rupert, to Siding No. 9, mile 301, inc., pending judgment in inquiry into rates charged generally by Ry. Cos. in B.C.; said tariff, with copy of this Order, be published in at least two consecutive weekly issues of "The Canada Gazette."

20442—September 26—Approving location C.P.R. station at Regent, on its Boissevain-Lauder Branch, Manitoba.

20443—September 30—Extending until April 30th, 1914, time within which C.P.R. complete branch lines for P. Burns and Company, Limited, Calgary, Alta., authorized under Order No. 19761, dated July 5th, 1913.

20444—September 30—Approving location C.P.R. station at Foremost, Alta., on its Weyburn-Stirling Branch, on centre line of North and South road allowance, between Secs. 16 and 17-6-11, W. 4 M.

20445—September 29—Directing that C.P.R. fence its right-of-way from mileage 91.3 to mileage 91.8, north of Rutter Station, on both sides of track; and from mileage 89.8 to 89.3, south of Rutter Station, on west side of track only.

20446—September 30—Authorizing C.P.R. to construct a diversion of the road allowance in Sec. 7-22-25, W. 4 M., Alta. Also authorizing company to construct, by means of grade crossing, its Gleichen-Shepard Branch Line across said diversion at mileage 19.00 of said branch. After diversion is made and crossing constructed thereon, in accordance with Regulations of Board, company may close that portion of road allowance between Sec. 7-22-25, and Sec. 12-22-26, W. 4 M., to be diverted as aforesaid, within limits of its right-of-way.

Tarvia

Preserves Roads
Prevents Dust~

Section of Government Parkway, Ottawa, Canada, treated with "Tarvia B."

Dust is Expensive

When an automobile speeds down an ordinary macadam road it leaves in its wake a cloud of dust which is carried by the winds over the neighboring fields, houses and lawns.

This is just as surely a waste of good material as if the automobilist dug material out of the highway and carted it away. Dust represents waste—costly waste—and the taxpayers feel the result. A road that is properly built for modern traffic will not be dusty.

Plain macadam gives way under the wear and tear of heavy rubber-tired automobile wheels and the surface binder of the road is torn away in the form of dust, until in time the coarse stone itself is exposed and a costly renewal of the road is necessary.

Modern roads should be built to resist modern traffic. To build any other kind is wasteful. A better binder than the ordinary mineral binder is needed and is offered in Tarvia, a coal tar compound especially prepared for use on roads.

Tarvia is dense, viscid, waterproof. It fills the interstices between the stone and forms a tough, plastic matrix. This makes a waterproof and automobile-proof surface. The maintenance cost is usually so low as to more than balance the cost of Tarvia treatment.

RAILWAYS—STEAM AND ELECTRIC.

Brandon, Man.—Mr. Gibson of the Grand Trunk Pacific, has stated that, in spite of rumors to the contrary, the company has received a special grant from both the provincial and Dominion Governments to build its line into Brandon, and that, though at present there is a delay caused by certain property owners, the line will be constructed eventually to come into the city.

Cardston, Alta.—Considerable satisfaction is being expressed by those who will be benefited by another line announced by the G.T.P., to run through the Pas to the Western Coast. The country is an important one financially for railways and the building of the new line, which will run westward from Medicine Hat and Lethbridge, will start early in the coming spring.

Edmonton, Alta.—Mr. H. D. Thompson, owner of Lot 96, Block 11, H.B.R., has asked permission from the city and railway commission board to have a spur track run down the lane to his building, which is erected on the above mentioned track.

Fredericton, N.B.—It is reported that favorable progress has been made with track laying on the Valley Railway, and that the first sixteen and a half miles to Kelly's Creek will be ready for the steel. This part of the work is being done by the Hibbard Construction Company. Messrs. Scott and Kelly, the local contractors, who have the Woodstock-Meductic section of the line, have their portion almost in readiness for steel. The Valley Railway will enter into an arrangement with the C.P.R. for the use of its trackage in Fredericton.

Montreal, Que.—The annual meeting of the shareholders of the Candian Pacific Railway Company ratified the proposals of the board of directors in the matter of building new connecting lines in the northwest aggregating about 750 miles, and including both a branch line running from a point near Swift Current on the Saskatchewan main line to Sedgewick, a distance of 290 miles, and the Weyburn branch line, a distance of 436 miles.

+—Montreal, Que.—The contract for the electrification of the Mount Royal tunnel has been awarded to the CANADIAN GENERAL ELECTRIC COMPANY. Particulars concerning the service which has been planned between Montreal and Mount Royal appear elsewhere in this issue.

Moose Jaw, Alta.—Permission has been granted the C.P.R. Company to lay spur tracks crossing Twentieth Avenue West, within 500 feet of its right of way, for the accommodation of the linseed oil plant.

Port Arthur, Ont.—An extension to the Port Arthur street car system is being constructed on Hodder Avenue. The roadbed is being made ready for the rails and ties are down on a portion of the way.

Port Arthur, Ont.—The C.N.R. are endeavoring to improve the condition on the Pee Dee railway. The road bed from Slate River as far as Silver Mountain is being newly ballasted and many new ties are being placed.

Regina, Sask.—The G.T.P. Railway Regina-Boundary line has been completed and connected with the Great Northern Railway. It is soon to be inspected by railway officials and Regina business men.

Vancouver, B.C.—In the opinion of Mr. R. N. Morrow, of Seattle a former resident of Vancouver and Victoria, a railway connecting Vancouver Island and the mainland will be a certainty in the next few years. The project would be one entailing an expenditure of millions of dollars, since it would mean the construction of a bridge several miles in length at a point on the Seymour Narrows where the separation between the island and mainland is least, where the water is shallow, and where there would be solid rock foundation. It would mean, moreover, one of the greatest of engineering feats in bridge building of modern times, but expert engineers in railway employ admit, that when the freight traffic demands this outlet and port of entry, this railway extension and bridge will be established.

GARBAGE, SEWAGE AND WATER.

Calgary, Alta.—The ratepayers have passed a by-law authorizing the expenditure of $63,140 for sewers for Ogden.

Calgary, Alta.—The Board of Control are of the opinion that when city pipe line carries Shoal Lake water into the corporation, there will be no more danger of shortage in water supply. From all indications the Shoal Lake district will furnish a water supply of great duration.

Fort William, Ont.—Tenders will be received up till October 10th, 1913, for tile sewer. Plans and specifications may be obtained from M. McCulloch, Fort William, Ont.

Kerrisdale, Point Grey, B.C.—In connection with the joint water main that is being constructed by Vancouver and Point Grey to supply water to the district from Capilano Creek, authority has been granted Engineer Cameron of Messrs. Cleveland and Cameron by the council, to sink one test bore in the bed of False Creek, in order to ascertain the nature of the foundation available for the water main.

70 % saving in joints

can be effected by using MANNESMANN TUBES, as they can be supplied in lengths up to forty feet. This means a reduction of from sixty to seventy per cent. in number of joints, jointing material and labor. Not only is actual money saved but safety is increased as there are proportionately fewer possible points of leakage. The total net cost of Mannesmann Tubes, when laid, is very low on account of the saving in joints and the speed with which the mains can be laid.

Mannesmann Tube Co.

51 Victoria Square **Montreal** Limited

+—**Lindsay, Ont.**—The contract has been awarded GEO. H. LINDSAY by the town council for the construction of a sewer on Queen Street.

Mawer, Sask.—A flowing well has been discovered at the town of Mawer, about 90 miles from Regina, and at the end of the steel of the Grand Trunk Pacific Regina-Moose Jaw Northwestern branch. The town will construct a reservoir to hold the supply for its use. The water is soft and contains no trace of alkalinity.

Ottawa, Ont.—Sir Alexander Binnie's report on the Gatineau water supply scheme was handed to Mayor Ellis yesterday afternoon. City Engineer Currie also presented a report on the feasibility of using the Ottawa River water, with filtration. Both reports will be made public.

+—**Outremont, Que.**—The contract for the new sewer on Wiseman Avenue from Ducharme to the Canadian Pacific Railway tracks has been awarded TOWN ENGINEER DUCHASTEL, his estimate of $1,532 being the lowest offered.

Toronto, Ont.—Plans for one of the greatest public works undertaken in Toronto have been completed by the works department. Ninety miles of sewers are to be laid in the northern half of the city, including old North Toronto, Moore Park and Cedarvale, estimated at a cost of several million dollars. The scheme designed for the North Toronto section will be the most costly, involving an expenditure of at least between two and three million dollars. It provides for a system of storm sewers and domestic sewers that will be adequate for North Toronto when thickly settled. A domestic sewage system was installed in this section two years ago, but it is now inadequate and must be enlarged and extended, while a complete new system of storm sewers will have to be laid. It is proposed to construct first the Moore Park section at a cost for the eastern section of $88,000; for the western section, $460,000. A huge trunk sewer, seven feet in diameter, is to be built on Summerhill Avenue which will provide for the sewage of both Moore Park and Cedarvale. Waste matter will be carried down the Don Valley to Ashbridge's Bay.

Vancouver, B.C.—Financial arrangements are about completed by the Burrard Joint Sewage Commission, which will enable a start to be made on either the Clark Drive and Canoe Creek portions of the proposed trunk sewer system for Greater Vancouver. It is expected that tenders will be called for soon that the work may be begun without delay.

Vancouver, B.C.—With a view to settling the location of the Vancouver and Point Grey water main, City Engineer Fellowes is drawing up plans and specifications and giving an estimate of the cost of the route he proposes across False Creek to the Kitsilano reserve, while Municipal Engineer Cameron has been instructed to submit like plans and estimate for the route which be proposes from the end of Bute or Thurlow streets. These will be submitted to and passed upon by the civic water committee.

+—**Windsor, Ont.**—The contract has been awarded BENJAMIN OLDANI, of Windsor, and WALTER C. WIGLE, of Amherstburg, for the construction of the Long Marsh drain, to commence at the turnpike road in Malden and run into the Canard River in Alderdon, a distance of about eight miles. The tender accepted was $13.84 per rod, or $38,000 for the entire work.

+—**Winnipeg, Man.**—The contract has been awarded the DOMINION CONSTRUCTION COMPANY of Winnipeg, by the municipality of Kildonan, to construct a sewer on Oakview Ave. The contract price is $5,232.70.

Winnipeg, Man.—Ratepayers have unanimously endorsed the $13,500,000 by-law of the Greater Winnipeg water district. This means that work will be commenced at once on the Shoal Lake project.

LIGHT, HEAT AND POWER.

+—**Abitibi, Ont.**—The Abitibi Pulp and Paper Co., have given the CANADIAN GENERAL ELECTRIC CO., LIMITED, the contract for electric motors ranging from 400 horsepower downwards, and aggregating 2,165 horsepower for their new mills at Iroquois Falls, Ont.

+—**Donnaconna, Que.**—The Donnaconna Paper Co. has placed an order for electric motors ranging from 150 horsepower downwards, and aggregating 1,330 horsepower, with the CANADIAN GENERAL ELECTRIC CO., LIMITED.

Elko, B.C.—The work of piping the water of Silver Spring Lake for the use of Elko's waterworks system, has commenced. The water is to be delivered by the gravity supply system, and an initial outlay of $22,000 is contemplated. In the opinion of engineers, this will mean the establishment of many industries here to avail themselves of Elko's immense water power resources.

Estevan, Sask.—The by-laws, approximating almost $36,000, which provide for standard street lighting, extension to power plant and light service, and for sewer expansion, were passed by large majorities. Work is to be rushed, so that all improvements will be completed this fall.

+—**Hamilton, Ont.**—The contract for the Hughson Street sub-station electrical equipment was awarded by the Hamilton board of control to the WESTINGHOUSE COMPANY, the contract price being $17,000.

Medicine Hat, Alta.—Tenders for the installation of the third unit for the municipal power plant have been called, and must be in by October 10th. This unit is to be set in operation with the least possible delay, since the two units supplying the city's electric power are almost taxed to their capacity.

Moose Jaw, Sask.—The chairman of the Light and Power committee of the city council has stated that 63 new street lights are to be installed throughout the city.

Newmarket, Ont.—Considerable criticism is being heard in Newmarket concerning the delay in solving the problem of electric power. It will be remembered that the ratepayers voted down a contract made between the town council and the Toronto and York Radial Railway Company for the supply of power to the municipality.

Ottawa, Ont.—Tenders will be received up till October 8th for water supplies in three New Brunswick towns. Plans and specifications may be obtained from L. K. Jones, Assistant Deputy Minister and Secretary, Department of Railways and Canals, Ottawa, Ont.

Ottawa, Ont.—Tenders will be received up till October 16th, 1913, for the heating and ventilation of the post office building, Quebec, P.Q. Plans and specifications may be obtained from R. C. Desrochers, Secretary, Department of Public Works, Ottawa, Ont.

Ottawa, Ont.—The council for the village of Eastview has decided to install 18 new street lights in the municipality.

Regina, Sask.—The installation of an artificial gas plant is being agitated at Regina. At the commencement of the year the city council committed itself to the project by setting aside $25,000 to be used for laying gas mains at lane intersections of streets where pavement was being laid. It is believed now that a plant will be installed at the commencement of the coming year.

Regina, Sask.—To increase further the lighting of Regina streets is the aim of the business men and city council, but difficulty is being met in coming to a definite decision upon the system to be employed. Meetings are being held for the purpose of discussing the merits and demerits of arc lamps and the standard pillar tungsten system of lighting.

+—**Toronto, Ont.**—The contract has been awarded the CANADIAN GENERAL ELECTRIC CO., LIMITED, by the Hydro-Electric Power Commission of Ontario for six transformers, each 3,500 k.w., 46000/2300 volts.

+—**Vancouver, B.C.**—The Canadian Collieries, (Dunsmuir), Limited, have decided to install an extensive electric-driven pumping plant. There will be four separate units, two of which will be driven by 75 horsepower a. c. motors, a third by a 75 d. c. motor, each unit being capable of delivering 350 gallons per minute against a head of 370 feet. The fourth unit will consist of two pumps working in series which will deliver 350 gallons per minute against a head of 740 feet. The pump will be built by the CANADIAN ALLIS-CHALMERS, LIMITED, and the motors by the CANADIAN GENERAL ELECTRIC CO., LIMITED.

Winnipeg, Man.—Tenders will be received up till October 8th, 1913, for the supply and installation of the necessary apparatus for gas testing stations. Plans and specifications may be obtained from M. Peterson, Esq., Secretary, Board of Control, Winnipeg, Man.

Winnipeg, Man.—Tenders will be received up till October 13th, 1913, for the supply of carbon flame arc lighting equipment. Plans and specifications may be obtained from the City Light and Power Department. Signed, M. Peterson, Secretary, Board of Control, Winnipeg, Man.

BRIDGES, ROADS AND PAVEMENTS.

Calgary, Alta.—In view of the fact that the by-law for paving the Nose Creek Road has been defeated, the Commissioners have decided to gravel the road and roll it, making a sort of macadam, to serve the present needs of the city's sanitary department. The cost of carrying garbage to the Nose Creek incinerator on the heavy trucks and wagons of the department will be decreased by the improved condition of the road.

Fredericton, N.B.—The international commission, to which the United States referred the matter of spanning the St. John River with a railroad bridge, has reported to the secretary of war for the United States and, to the Minister of Public Works for the Dominion of Canada, favoring the building of the bridge to connect Van Bureu in Maine with St. Leonards in New Brunswick. The commission holds, moreover, that the construction of the bridge will not violate the terms of the treaty of 1842 between Great Britain and the United States.

+—Montreal, Que.—The contract has been awarded JOHN S. METCALF CO., LIMITED, constructing engineers, Montreal and Chicago, by the Canadian Pacific Railway Company for the extension of the Glen Arch at Westmount, Montreal, to provide for a width of four tracks at an estimated cost of $50,000.

Montreal, Que.—The Board of Control is already at work upon its program for next year's paving operations, and it is expected to amount in extent and cost to the work done on pavements this year, aggregating around 2,500,000 dollars of expenditure.

North Vancouver, B.C.—A road which will cost approximately $25,000 is to be constructed by the Provincial Government. It will be of macadam, and will run along the waterfront, thus providing a through road from the city to the district in the east on a low level, avoiding the steep grades which residents now have to ascend.

Saskatoon, Sask.—Good progress is reported upon the new bridge under construction here, and it is expected that all of the piers will be placed during the fall and winter.

+—Vancouver, B.C.—Arrangements have been made with the CANADIAN MINERAL RUBBER COMPANY for paving Gorge Road when they have completed the work on Douglas Street. As in the agreement for Douglas Street paving, the city will do the underground work, and the company the surface work. The work is to proceed without delay.

Victoria, B.C.—The plans for the C.N.P. railway bridge over Selkirk water have been filed. They call for a bridge of the Bascule type to be constructed with pile trestles 15 feet apart, with the exception of two openings of 60 feet and 25 feet respectively for the passage of boats. The clearance of the bridge above extreme low water will be 23 feet.

Winnipeg, Man.—A new system of roads giving the settlers on the east shore of Lake Manitoba access to railway lines and to the main north and south road, known as the Fairford Road, is now complete from Oak Point north to Fairford.

INDUSTRIAL WORKS.

Brantford, Ont.—The excavation work on the island above Lorne Bridge has been examined by an engineer of the Dominion Railway Board, and is reported as by no means finished. Four feet of excavation below the surface of the water is still to be made.

▲—Halifax, N.S.—Tenders will be received up till October 22nd, 1913, for the construction of about 6,500 lineal feet of quay wall, foundations of buildings, sewers, dredging of harbor and filling reclaimed areas. Plans and specifications may be obtained from the Department of Railways and Canals, Ottawa. L. K. Jones, Assistant Deputy Minister and Secretary.

Medicine Hat, Alta.—The work of repairing the concrete floor of the new filtration plant, which was damaged some time ago by the buckling of a large water pipe which flooded and washed away the ground beneath the floor, allowing it to sag so that it cracked, is progressing slowly but surely. It has been necessary to break holes through the concrete floor to locate the course taken by the water, and this has taken considerable time. A special kind of pump has been installed with which concrete is being forced at a pressure of 100 pounds to the square inch into apertures to fill up the voids beneath the floor caused by the erosion of the water. The city engineer has no doubt but that the new filtration plant and power station will be in use this fall.

Montreal, Que.—Superintendent Lesage of the city waterworks, has announced that, in addition to the two new twelve-million gallon pumps which are being installed at the pumping station this autumn, the great increase in Montreal's water consumption has already made necessary the preparation of plans for two more pumps of the same capacity which are to be delivered next June.

Ottawa, Ont.—Tenders will be received up till October 15th, 1913, for the construction of breakwater at Little Dipper Harbor, N.B. Plans and specifications may be obtained from F. G. Goodspeed, Esq., District Engineer, St. John, N.B. Signed, R. C. Desrochers, Secretary, Department of Public Works, Ottawa.

Ottawa, Ont.—Tenders will be received up till October 29th, 1913, for the construction of a breakwater at Kincardine, Ont. Plans and specifications may be obtained from R. C. Desrochers, Secretary, Department of Public Works, Ottawa, Ont.

Ottawa, Ont.—Tenders will be received up till October 27th, 1913, for the construction of a training pier and revetment wall at Poupore, Labelle Co., Que. Plans and specifications may be obtained from R. C. Desrochers, Secretary, Department of Public Works, Ottawa, Ont.

Ottawa, Ont.—Tenders will be received up till October 28th for the construction of wharf improvements at St. Jean Port Joli, L'Islet Co., Que. Plans and specifications may be obtained from R. C. Desrochers, Secretary, Department of Public Works, Ottawa, Ont.

Ottawa, Ont.—Tenders will be received up till October 29 for the construction of an extension to the wharf and dredging at Chocolate Cove, N.B. Plans and specifications may be obtained from R. C. Desrochers, Secretary, Department of Public Works, Ottawa, Ont.

Ottawa, Ont.—Tenders will be received up till October 29th for harbor improvements at Thornbury, Grey County, Ont. Plans and specifications may be obtained from J. G. Sing, Esq., District Engineer, Confederation Life Building, Toronto. Signed, R. C. Desrochers, Secretary, Department of Public Works, Ottawa, Ont.

Ottawa, Ont.—The work on the St. Lawrence channel at the Traverse below Quebec has been completed. The result is that a widening of 250 feet with a depth of 30 feet at low water has eliminated one of the few remaining obstacles to easy navigation on the river.

Ottawa, Ont.—Tenders will be received up till October 15th, 1913, for the construction of a breakwater at Comeau's Cove, Digby Co., N.S. Plans and specifications may be obtained from R. C. Desrochers, Secretary, Department of Public Works, Ottawa, Ont.

Sault Ste. Marie, Ont.—A further step towards the improvement of navigation on Canada's inland waterway is shown in the announcement of the Hon. Mr. Cochrane, that land is being expropriated at the Soo for a new canal. To deepen the Welland Canal to 31 feet and to leave the Soo Canal at its present depth of 21 feet would be no gain to transportation.

Vancouver, B.C.—Mr. H. H. Stevens, M.P., has stated that the Dominion Government has completed arrangements for a dock on the Indian Reserve, north shore. This is a 500,000 dollar project, and the progress of plans now rests with the provincial government.

Vancouver, B.C.—Instructions have been put into operation for the widening of the First Narrows by a distance of 200 feet on the north side, and for increasing the depth 40 feet. Then the necessary slope will be cut for a water main pipe to run down and to have its skidway extended backwards for 400 feet. The extra length of skidway is to be constructed at once, so that when the weather and tides permit, the two 18-inch mains may be pulled across. The two sections of pipe now built have been disconnected to allow for the dredging being done without intereference from the pipe.

West Vancouver, B.C.—A by-law is to be submitted to ratepayers to provide for the expenditure of money required for the construction of a wharf at the foot of Twenty-Fifth Avenue.

MISCELLANEOUS.

+—Brandon, Man.—The contract for the steel work at the street car barns has been secured provisionally by the BRANDON MACHINE AND IMPLEMENT WORKS, the contract tender being $12 per ton.

Calgary, Alta.—The Calgary ratepayers have carried a by-law authorizing the issuance of $350,000 in bonds for the establishment of stock yards; a by-law providing for the construction of a building for infant industries to cost $250,000; and a by-law for the building of a $30,000 hospital for tubercular diseases.

Claresholm, Alta.—It is reported that favorable progress is being made upon the Alberta Farmers' Co-operative elevator under construction at Claresholm.

Nanaimo, B.C.—Plans for the proposed improvements to the Nanaimo post office and customs building have arrived from Ottawa, and it is expected that within a few days tenders will be called for the proposed addition, for which a grant of $25,000 was secured from the Dominion Government.

Newcastle, N.B.—It is stated that steel from England has arrived for the construction of the 500-foot tower to be erected at the new wireless station at Newcastle. The foundation is complete, and the construction of the six 300-foot wooden towers is well under way.

Port Arthur, Ont.—An English syndicate is having prepared plans for a fireproof theatre with a seating capacity of 1,200, for which Rutton and Co. are the agents and Hood and Scott, the architects. Tenders for construction will be called in a few weeks.

Regina, Sask.—The Regina Plumbing and Heating Company has decided to erect an addition to its building at Regina. Storey and Van-Egmond, architects, are preparing plans.

+—Saskatoon, Sask.—The contract for the construction of the first unit of the Dominion Government interior storage elevator has been awarded to the BARNETT McQUEEN COMPANY of Fort William, their tender of $1,000,000 being the lowest received. This unit will have a capacity of 3,500,000 bushels, and is to be completed by December, 1914.

+—Stratford, Ont.—The contract has been awarded MESSRS. POUNDER BROTHERS, by W. J. McCully, for the erection of a concrete storehouse, 70 feet by 30 feet, and two stories in height.

Vancouver, B.C.—The Vancouver Industrial Sites, Limited, has taken over the real estate of the Imperial Car and Drydock Co., for the equivalent value granted in fully paid-up stock in the new company, and have assumed all the liabilities of the old company. The Vancouver company have purchased from the Vancouver Industrial Sites, Limited, a site of 12 acres for the sum of $200,000, and will begin at once the erection of dry kilns and an addition to the saw mill already on the property. The Vancouver Industrial Sites, Limited, are now owners of about 450 acres of property at Roche Point across the Inlet with a water frontage of 6,000 feet. This they propose to sell exclusively for manufacturing sites.

Vancouver, B.C.—Tenders will be received up till October 9th, 1913, for the supplying of fuel oil to the B.C. Dredging Fleet for a period of three years. Plans and specifications may be obtained from J. L. Nelson, Esq., Superintendent of Dredges, Rm. 40, Post Office Building, Vancouver, B.C.

Vancouver, B.C.—Reeve Bridge has interviewed the government with regard to making a special survey of the upper end of Lulu Island. Surveys which have been made since the original stakes were burned, have been taken from an incorrect base line, and the whole survey of that end of the island is at fault.

Vancouver, B.C.—Expert engineers are of the opinion that the paraffin oil struck at Pitt Meadows is of high grade quality and also of great quantity. But, owing to the large quantity of water in the 1,300-foot well already bored, preventing the oil from reaching the surface, the promoters have decided to cover this well and to drill immediately another.

Victoria, B.C.—Towards Christmas, tenders will be called for the construction of the new Jubilee Hospital, according to Mr. Loring P. Rixford of San Francisco, the architect. The estimated cost of all buildings included is $399,840.

Winnipeg, Man.—Tenders will be received up till October 10th, 1913, for the manufacture, delivery, installation, and testing in the Grand Trunk Pacific shops at Transcona, of transformers and switching apparatus. Plans and specifications may be obtained from M. Peterson, Esq., Secretary, Board of Control, Winnipeg, Man.

+—Winnipeg, Man.—The contract has been awarded the JOHN DOLMAN COMPANY, Winnipeg, for the installation and bricking in of the boilers to be placed in the new power plant at a cost of $5,700.

Winnipeg, Man.—Tenders will be received up till October 10th, 1913, for the manufacture and delivery of two 44 K.V.A. induction feeder regulators and accessories. Plans and specifications may be obtained from M. Peterson, Secretary, Board of Control, Winnipeg, Man.

CURRENT NEWS.

Calgary, Alta.—D. C. Coleman, Esq., general superintendant of the Alberta division of the C.P.R., announced, after inspecting the work on the new Lethbridge-Weyburn line, that that piece of railway will be sufficiently complete to allow the movement of grain on that branch this season.

Cambie, B.C.—It is proposed to place an emergency water main across the Lulu Island bridge to guard against an interrupted supply of water in the event of a break in the pipes on the bed of the stream. The pipes are to be carried over the bridge as far as the draw span, then submerged, the bed of the river being dredged there so as to place them on a solid foundation about four feet below the river bed. This will prevent an undermining of the pipes by the current, the chief cause of breaks in the present system. The pipes used will be solid jointed steel pipes.

Castor, Alta.—The gas well at Castor has proven itself a complete success. The well has been safely capped, and the first time after 18 hours registered a pressure of 262½ pounds to the square inch; the second, when leaks in the pipe had been stopped, a pressure of 270 pounds to the square inch. This is a pressure greatly in excess of the Vegreville gas well, which, after 24 hours, registered only 167 pounds to the square inch.

Edmonton, Alta.—Though the city engineer and superintendant of the street railway department are of the opinion that the measures taken to guard against accidents on the high level bridge are sufficient, yet the matter is being given much consideration by citizens, and has been brought before the city commissioners, requesting them to provide further precautionary measures.

Edmonton, Alta.—Messrs. F. G. Clapp and L. G. Huntly, gas experts of Pittsburg, have submitted a report concerning the delivery of natural gas to Edmonton consumers. They visited the districts of Vegreville, Pelican Falls, Wetaskiwin, Morinville, Tofield and Athabasca, and reported the first-mentioned as the most promising, though all possess merit. They stated that gas can be delivered from Vegreville at 9 cents per 1,000 cubic feet, owing to the short distance to be covered by the pipe line. The pipe line and plant they considered would cost about $3,850,000.

Fort William, Ont.—Inside of three weeks, the formal opening of the bascule bridge for railway, vehicular, and pedestrian traffic, is expected to take place. The nature of the opening ceremony is not yet determined.

Guelph, Ont.—The Eramosa hill road has been completed at a cost $2,045.61 less than the estimate, and the construction is declared to be entirely satisfactory. Storm drains were installed for $1,948.31, and the cost of the roadway itself was $7,300.

Hamilton, Ont.—Considerable agitation is being raised over the removal of sand from the beach near the filtering basin, and City Solicitor Waddell has been authorized to obtain an appointment with the Hon. Mr. Hurst to endeavour to get final authority in restraining the people from removing the sand.

Kingston, Ont.—The Board of Health have taken up the matter of the city's drainage, with the result that efforts are beginning to be made by the city officials to produce an adequate drainage system.

Why Lose Time "Shopping"

When You Can Buy Anything You Want

"Under One Roof"?

It is just as great a convenience to engineers, contractors and builders to be able to get their supplies from one house as it is to the general public to shop in a large modern department store. The rise of the department store has been the result of economic conditions.

Likewise our business has evolved into a departmental house in the mechanical world in obedience to the same economic law.

This bringing together of a vast number of lines and classifying them according to departments is the kind of combination in industry that makes for efficiency, economy and better service.

Canada's Departmental House for Mechanical Goods

Can supply you with material all the way from nuts to machine tools and oil engines.

Our business is divided into about a dozen diff rent departments, as follows:—Scale Department, Engine Department, Valve and Steam Goods Department, Pump Department, Electrical Department, Transmission Department, Railway and Contractors' Supply Department, Small Tool and Supply Department, Safe and Typewriter Department, and Motor Truck Department.

From time to time we advertise products from the different departments that we think readers of *The Canadian Engineer* are interested in, but you should not by any means infer that those are the only goods we handle.

In this new series of advertisements we wish to drive home the fact that we are literally a "Departmental House for Mechanical Goods."

All you need to do is to make known to us your requirements. Write, telephone, or call.

The Canadian Fairbanks-Morse Co.

LIMITED

"The Departmental House for Mechanical Goods"

2

Lindsay, Ont.—The Trent Valley Canal, according to plans scheduled, is to leave Lake Couchiching about a mile to the west of Washago, and cut across to a point below Severn Bridge. The residents of Washago have suggested an alternative route, by which the canal would leave the lake near that village, but small hope for the change in plans can be entertained, since the latter route involves rock cutting for most of the way.

MacLeod, Alta.—It is the opinion of elevator authorities that the Alberta Pacific Elevator Company will construct one of the terminal elevators proposed to be erected, at MacLeod. The present elevator located here is being worked to its full capacity.

Montreal, Que.—The Electrical Service Commission has communicated to the Board of Control that all overhead wires and cables on St. Catherine and Bleury Streets will be underground by May 1st of next year. It also suggests the adoption of a city by-law by which all buildings under construction and those constructed in future be so wired as to permit of underground connections being eventually made.

Montreal, Que.—The C.P.R. have announced that the opening of the new six million dollar dam at Bassano, Alta., will take place on October 1st. The dam has been constructed in connection with the project of checking the Bow River for the irrigation of the land of that vicinity of Western Canada.

New Westminster, B.C.—The first freight train has been operated over the section of the C.N.R., between the centres of Port Mann and Hope. A twice-a-week service is to be operated on this line for the accommodation of the company and nearby residents.

North Vancouver, B.C.—The company of Royal Engineers has finished the construction of a suspension bridge on the Fidler system over the mouth of Mosquito Creek. The bridge is of one span, 90 feet in length, suspended from wire cables, supported on both banks by heavy buttresses, and is capable of carrying a weight of 14 tons without straining.

Ottawa, Ont.—The St. Lawrence Power Company, Limited, capitalized at $5,000,000, and with headquarters at Toronto, have been granted letters patent by the Dominion Government. The company is inaugurated to develop power and to carry on the varied enterprises connected therewith.

Ottawa, Ont.—The foundations of the new Canadian Northern Railway shops have been laid, and the works at Rideau Junction will doubtless be finished early in the spring.

Ottawa, Ont.—A semi-official statement has been made announcing that the section of the National Transcontinental Railway from Cochrane to Winnipeg will be taken over by the Grand Trunk Pacific in the spring. According to the agreement made under the Laurier Government, the G.T.P. are not compelled to take over the line until it is absolutely complete. Trains can now be run over the line, but only for freight purposes, many bridges as yet being only temporary constructions, and several sink holes still needing further filling and grading.

Peterboro, Ont.—The city's sewage disposal scheme must be postponed until it has been conformed to the alterations suggested by Provincial Board of Health.

Regina, Sask.—The city council is drawing up plans for extensions to the local improvement works, particularly in the south and south-west sections of the city, and in the warehouse section. By-laws providing for the raising of $650,782 to be used in paving construction and for the sale of $110,427 of debentures for concrete sidewalks have been approved by the council. Though some suggestions have been made that the work involved be done by day labor, instead of by contract, it is not probable that the city council will not approve of such an arrangement.

St. John, N.B.—A new water main, which will solve the water problem of Partridge Island, is being laid by the Department of Public Works. The new main is a flexible bronze pipe in sections of from 30 to 40 feet in length and 4 inches in diameter. Up to the present 1,000 feet have been laid, and though about 2,000 feet more must be laid, the work will be completed inside of three weeks.

Vancouver, B.C.—Mr. Cottrell, the district superintendent, announces rapid progress on the transforming of locomotives on the Canadian Pacific subdivision between Vancouver and North Bend into oil burners. Out of 40 locomotives on the division, half have been adapted for the new order of fuel.

Vancouver, B.C.—The following resolution, agreeable to both the bridges and railways committee and Mr. Bolschweller of the B.C. Telephone Company, regarding the conduits to be placed on the Georgia-Harris bridge, has been passed:—"That in the construction of the Georgia-Harris Street viaduct, inserts and manhole castings be installed by the company under the supervision of the city's engineer, according to the plans submitted by the B.C. Telephone Company, it being distinctly understood that no permission is to be construed from the passing of this resolution giving the right to the company to install conduits in such inserts and manhole castings, and such conduits shall only be installed on such condition as the city may approve in the future."

Vegreville, Alta.—Messrs. Clapp and Huntley, gas experts, who have been investigating the possibilities of gas fields within a radius of some 200 miles of Edmonton, have reported that Vegreville is the centre of the best gas-producing district in Northern Alberta, and have advised the city of Edmonton to acquire lands there and to bore for gas. They advise that the city should lay aside $100,000 to be used at once in boring four wells south-east of Vegreville, on four specific locations minutely described in the report. These wells, it is recommended, should be drilled to a depth of at least 2,000 feet, and the first well, if necessary, should be sunk to a depth of 2,200 feet. The experts are confident gas will be found in large quantities in these locations.

Victoria, B.C.—The city of Victoria is considering the project of a number of its prominent business men to incorporate a motor bus company, in which every citizen may be a shareholder. It is proposed to capitalize the company at $500,000, with shares of $10 each.

TRADE ENQUIRIES.

The following trade inquiry relating to Canadian trade was received at the branch for city trade inquiries, 73 Basinghall Street, London, E.C.—A Scottish firm manufacturing wire rope would like to arrange for its sale in Western Canada.

MONTREAL MARKET LETTER.

The final passage of the United States tariff legislation has removed a prolific cause of uncertainty, not only in the financial market, but in iron and steel and general commercial circles throughout the United States. It has been claimed that the scarcity of contracts has been in a large part due to the uncertainty concerning what might take place with respect to the tariff on iron and steel, and that railways were delaying the placing of their orders so that they might be able to take advantage of any decline which might follow. This, it is claimed, has largely been accountable for the disappointment which has been experienced by the steel companies. It was expected that orders for steel rails and other railway equipment during the month of September would show a very considerable increase, whereas, the contrary was the result. Now that the tariff legislation has been finally settled, one might expect that orders would come out freely or that imports would shortly begin. It will doubtless take some little time for matters to adjust themselves and for new trade channels, whatever they may prove to be, to define themselves. It is claimed that the United States will be able to retain her trade in the face of any opposition which may be offered from Germany or other countries; and this doubtless will be the case if the statement that the cost of production of the United States is lower than other countries, is actually true.

Canada is deeply interested in the working out of the situation on the other side of the border and there can be little doubt that trade here has been awaiting, to some extent, the result. Seeing the delay of the United States, buyers in Canada have also been holding off, to this effect that, if prices across the border decline to any considerable extent, it will probably mean a readjustment, which will result in increased imports from the United States or a reduction in prices asked by Canadian furnaces and mills. Meantime, no price changes have been taking place in Montreal and none are likely to take place for a few days to come. Small orders are being placed right along, but it is thought that the larger contracts are being held back to a considerable extent awaiting the outcome of the readjustment on the other side of the border.

When designing

structures do you pay sufficient attention to the various matters that govern insurance ratings?

Not only can you add greatly to the fireproofness of buildings by adopting our suggestions, but it is very likely that you can do so without the improvements costing anything ultimately. They will be paid for by the lower insurance rates.

Correspondence solicited. We have a staff of engineers and inspectors trained in this highly specialized line. Make use of our services.

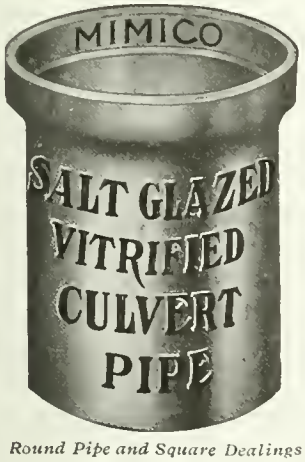
Cost of pipe = 20% cost of work
Saving by using poor pipe = 20%
Saving on total cost = 4%

IS IT WORTH WHILE?



If the sewer is to cost $10,000, for instance, MIMICO pipe would likely not cost more than $2,000, probably considerably less. Not more than $400 could be saved on this pipe cost by purchasing a poor grade of pipe. You would then have a poor sewer costing $9,600, when for $10,000 you might have had the very best sewer possible to build. Is it worth while to buy poor pipe? No! Then buy Mimico Brand and put an end to sewer troubles

Concrete Costs.

Tables and Recommendations for Estimating the Time and Cost of Labor Operations in Concrete Construction and for introducing Economical Methods of Management.

By FREDERICK W. TAYLOR, M.E., Sc.D., and SANFORD E. THOMPSON, S.B., Mem. Amer. Soc. C.E., Consulting Engineer. Small 8vo, xxii+709 pages, 82 figures. Cloth $5.00 net.

In this volume the authors have carefully described the best methods of dealing with the component parts of a construction job, and have so devised their cost tables that it will be possible by their use to estimate the cost of a proposed job much more accurately than by any method heretofore employed.

SECOND EDITION, Revised and Enlarged.

Concrete, Plain and Reinforced.

By FREDERICK W. TAYLOR and SANFORD E. THOMPSON. 8vo, xli+821 pages, 249 figures. Cloth, $5.00.

In this edition is included the developments in the design and construction of reinforced concrete since the issue of the first edition.

SECOND EDITION, Revised and Enlarged.

Principles of Reinforced Concrete Construction.

By F. E. TURNEAURE, Dean of the College of Engineering, and E. R. MAURER, Professor of Mechanics, University of Wisconsin. 8vo, x+429 pages, 17 plates and 164 figures. Cloth, $3.50.

Covers in a systematic manner, those principles of mechanics underlying the design of reinforced concrete.

TENTH EDITION.

A Treatise on Masonry Construction.

By IRA OSBORN BAKER, B.S., C.E., D. Eng'g., Professor of Civil Engineering, University of Illinois. 8vo, xv+745 pages, over 100 tables and 244 illustrations. Cloth, $5.00.

NINTH EDITION, Re-written.
TOTAL ISSUE—14,000.

The Theory and Practice of Modern Framed Structures.

JOHNSON—BRYAN—TURNEAURE

In three parts. Part I—STRESSES IN SIMPLE STRUCTURE. 8vo, xii+326 pages, illustrated with cuts throughout the text. Cloth, $3.00 net.
Part II—STATICALLY INDETERMINATE STRUCTURES AND SECONDARY STRESSES. 8vo, xvi+538 pages, 313 figures. Cloth, $4.00 net.
Part III—DESIGN. (In preparation.)

TENDERS CALLED FOR

Sealed tenders addressed to the undersigned, and endorsed "Tender for Breakwater at Kincardine, Ont.," will be received at this office until 4 p.m. on Wednesday, October 29, 1913, for the construction of a Breakwater at Kincardine, Bruce County, Ontario.

Plans, specification and form of contract can be seen and forms of tender obtained at this Department and at the offices of H. J. Lamb, Esq., District Engineer, Windsor, Ont.; J. G. Sing, Esq., District Engineer, Confederation Life Building, Toronto, Ont., and on application to the Postmaster at Kincardine, Ont.

Persons tendering are notified that tenders will not be considered unless made on the printed forms supplied, and signed with their actual signatures, stating their occupations and places of residence. In the case of firms, the actual signature, the nature of the occupation, and place of residence of each member of the firm must be given.

Each tender must be accompanied by an accepted cheque on a chartered bank, payable to the order of the Honorable the Minister of Public Works, equal to ten per cent. (10 %) of the amount of the tender, which will be forfeited if the person tendering decline to enter into a contract when called upon to do so, or fail to complete the work contracted for. If the tender be not accepted the cheque will be returned.

The Department does not bind itself to accept the lowest or any tender.

By order,

R. C. DESROCHERS,
Secretary.

Department of Public Works,
Ottawa, September 30, 1913.

Newspapers will not be paid for this advertisement if they insert it without authority from the Department.—46683.

Sealed tenders addressed to the undersigned, and endorsed "Tender for Harbor Improvements at Wellington, Ont.," will be received at this office until 4 p.m., on Wednesday, October 29, 1913, for the construction of Harbor Improvements at Wellington, Prince Edward County, Ontario.

Plans, specification and form of contract can be seen and forms of tender obtained at this Department and at the offices of J. G. Sing, Esq., District Engineer, Confederation Life Building, Toronto, Ont., and on application to the Postmaster at Wellington, Ont.

Persons tendering are notified that tenders will not be considered unless made on the printed forms supplied, and signed with their actual signatures, stating their occupations and places of residence. In the case of firms, the actual signature, the nature of the occupation, and place of residence of each member of the firm must be given.

Each tender must be accompanied by an accepted cheque on a chartered bank, payable to the order of the Honorable the Minister of Public Works, equal to ten per cent. (10 per cent.) of the amount of the tender, which will be forfeited if the person tendering decline to enter into a contract when called upon to do so, or fail to complete the work contracted for. If the tender be not accepted the cheque will be returned.

The Department does not bind itself to accept the lowest or any tender.

By order,

R. C. DESROCHERS,
Secretary.

Department of Public Works,
Ottawa, September 30, 1913.

Newspapers will not be paid for this advertisement if they insert it without authority from the Department.—46303.

EXTENSION OF TIME.

DEPARTMENT OF RAILWAYS AND CANALS, CANADA.

CANADIAN GOVERNMENT RAILWAYS.

Halifax Ocean Terminals Railway, Halifax, N.S.

Sealed tenders addressed to the undersigned and endorsed "Tender for docks, First Unit, Contract No. 3, Halifax Ocean Terminal," will be received at this office until twelve o'clock noon, Wednesday, the twenty-second day of October, 1913, for the construction of about 6,500 lineal feet of quay wall, foundations for buildings, sewers, dredging of harbor to a depth of 45 feet at low water, and filling reclaimed areas.

Plans and specifications and form of tender may be seen and full information obtained at the office of the General Manager, Moncton, N.B., at the office of the Chief Engineer of the Department of Railways and Canals, Ottawa, and at the office of the Superintending Engineer, Halifax, N.S.

The right is reserved to reject any or all tenders.

By order, L. K. JONES,
Assistant Deputy-Minister and Secretary.

Department of Railways and Canals,
Ottawa, September 2nd, 1913.

CANADIAN RAIL PRODUCTION.

The following table shows the production of steel rails in Canada during the past 18 years:—

Years.	Gross tons.	Years.	Gross tons.
1895	600	1904	36,216
1896	600	1905	178,885
1897	500	1906	312,877
1898	600	1907	311,461
1899	835	1908	268,692
1900	700	1909	344,830
1901	891	1910	366,465
1902	33,950	1911	360,547
1903	1,243	1912	423,885

STABILITY IN AERONAUTICS.

This is a title of a paper to be presented at the October 14th meeting of the American Society of Mechanical Engineers in New York, by Albert A. Merrill of Boston, the founder of the Boston Aeronautical Society, and a lecturer upon the subject of aeronautics at the Massachusetts Institute of Technology.

One of the most important questions in aviation is that of stability. Mr. Merrill has analyzed the forces involved in order to determine if, by a change in design, it is possible to increase the safety of the flying machine; and his paper is based upon the results of his research.

Experiments made to bring aluminum to a liquid condition, so that it may be spread when cold over any dry service, have been sucessful in Germany. The composition is applied like a paint with a brush, and looks, when spread, like a dull silver coating. It is said to be an excellent preventive of rust, to be resistant to heat, elastic, durable, and resistant to atmospheric influences, and to form an excellent substitute for tin in plating.

MEXICAN EAGLE ASPHALT

TRADE MARK

Mountain Street, Winnipeg, Man., paved with Mexican Eagle Asphalt.

Mexican Eagle Asphalt is the purest asphalt on the market. It is also a favorite among city engineers for its high cementing value and ductility. That means that sheet asphalt pavements constructed with Mexican Eagle Asphalt take first place among permanent pavements. Because there is no doubt but that sheet asphalt is in general the most satisfactory pavement. Read the experiences of a few Canadian cities:

OTTAWA, ONT.

Five-sixths of the thirty miles of permanent pavement in Ottawa is sheet asphalt. The principal business and residential streets are paved with it. The city engineer's department says that, if properly constructed, asphalt has been found to be about the best pavement they can have. Ottawa has a great many streets constructed with Mexican Eagle Asphalt.

WINNIPEG, MAN

Winnipeg has laid eighty-one miles of sheet asphalt since 1897, for all kinds of traffic. City Engineer Ruttan installed the first municipal asphalt paving plant in Canada. In their experience the asphalt has worn uniformly and has been extremely satisfactory, particularly the pavements constructed with Mexican Eagle Asphalt.

VICTORIA, B.C.

Sheet asphalt is practically the only kind of pavement laid in Victoria, only four out of the forty-eight miles of permanent paving being of any other type. It has been Victoria's experience that no repairs at all are necessary in the first five years, and extensive repairs are necessary only after ten years' wear.

TORONTO, ONT.

As in most cities, asphalt predominates in Toronto, over 157 mile of sheet asphalt pavement having been laid since 1887. The average cost of maintenance per square yard during ten years has been only slightly over five cents a year. For both residential and business streets it is the principal pavement. Many Toronto streets are laid with Mexican Eagle Asphalt.

LONDON, ONT.

The city engineer of London says that asphalt pavements in London that have been down nine years are in good shape and will likely be so for another four or five years. Of less than nine miles of pavement in London, over five miles are sheet asphalt.

HAMILTON, ONT.

Thousands of tons of Mexican Eagle Asphalt have been used in Hamilton during the past five years. Asphalt greatly predominates there, two-thirds of the thirty miles of permanent paving being sheet asphalt. The principal business streets are paved with it. The average cost of maintenance per square yard for the first five years has been two cents a year.

PATENTS.

October 6th, 1913.

The following is a list of patents for Canada recently issued through the agency of Messrs. Ridout and Maybee, 59 Yonge Street, Toronto, from whom further particulars may be obtained:—

Harrison A. Stringer and George R. Gamble, pumps for oil and gas wells; Harry A. Gaydon, sound producing devices; Fred. Gilbert, bronzing apparatus; Fred. T. Quirk, bellow springs; David J. Hurley, controllers for doors and like movable structures; Oswald Silberad, chlorate explosive; Ferdinand Weinberg, machines for moulding concrete pipes.

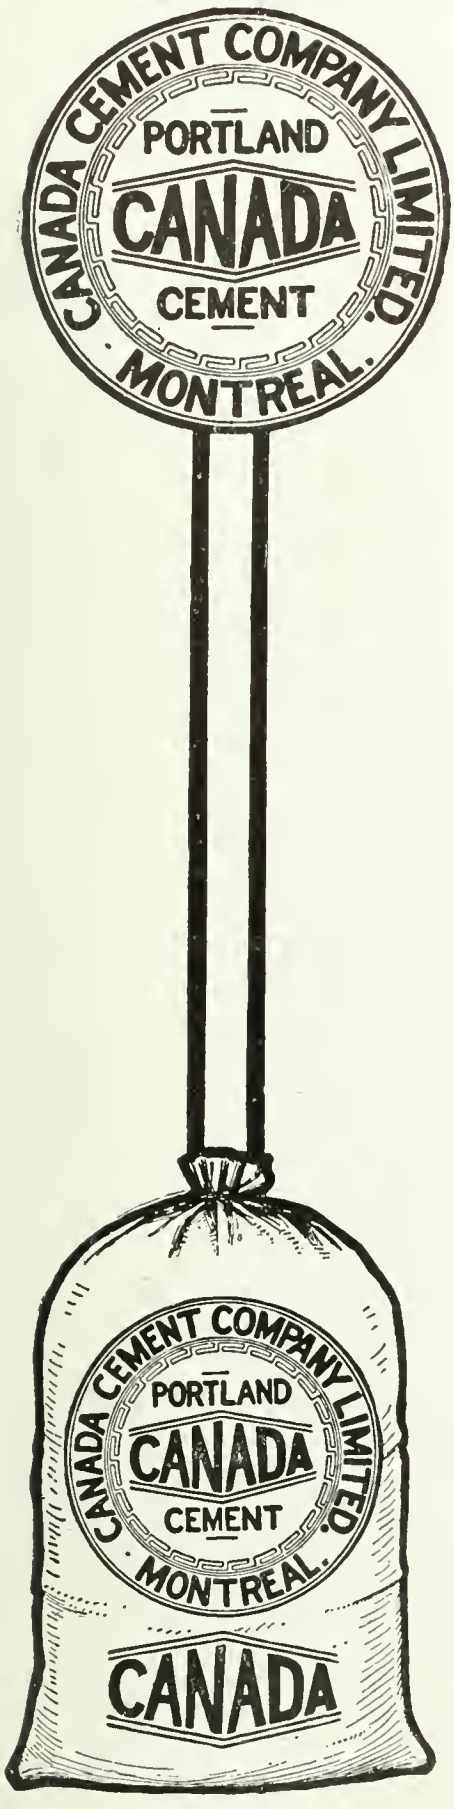
PERMANENCE—



an ideal that is now attainable

THE superiority of concrete over all other materials for the building of permanent structures is now generally admitted.

The next step towards ideal construction, is to realize that for satisfactory concrete work, it is necessary to use a cement that is uniformly high-grade

CANADA Portland CEMENT

is the selection of the leading engineers, architects and contractors. Their experience has proved that in this brand they can obtain a certainty of success.

With concrete coming into more and more general use for the construction of buildings, bridges, viaducts and highways, it is vitally important that those in authority on such matters should select the best materials obtainable.

Use the cement that our best architects and engineers have selected for their most important undertakings. Select Canada Cement — it costs no more than any others.

TAKE NOTICE that the undersigned are prepared to grant licenses, at a reasonable price, to anyone desiring to use the method of producing electric oscillations described and claimed in Canadian Letters Patent No. 119,908, issued on the 10th day of August, 1909, to Roberto Clemens Galletti. They are also prepared to receive offers for the purchase of the patent. Ridout and Maybee, 59 Yonge Street, Toronto, attorneys for Roberto Clemens Galletti.

FLANGES AND FLANGE FITTINGS—AMERICAN STANDARD.

The use of flanges and flange fittings has been increasing quite rapidly of late years. In fact, a flange joint is the standard form of connection in many classes of piping. For most purposes the ordinary screw connection should not be used above 6 ins. pipe size on account of the difficulty of making and breaking joints. As the flange fitting business grew, each manufacturer made up patterns for whatever sizes were called for, to his own personal ideas or knowledge at that time. These dimensions were later published in catalogues and a wide variation in dimensions was found. The variation in the diameter and thickness of flanges as well as the bolt circle, size and number of bolts on standard weight material, caused the users and manufacturers considerable confusion and expense.

This brought about the movement by the American Society of Mechanical Engineers and the Master Steam and Hot Water Fitters Association, assisted by the manufacturers of these lines, the result of which was the adoption of what is known as the A.S.M.E. Standard of 1894. This covered flange dimensions and bolting only. A few years later the manufacturers began to realize that the extra heavy 250 pound flanges and bolting were in the same state of confusion. This resulted in the adoption of what has been known as the Manufacturers Standard of 1901.

It became evident in the past few years that the centre to face and face to face dimensions of all flange fittings, including low pressure, standard pressure, and extra heavy pressure, should be established. After considerable work, a standard known as the 1912 U.S. Standard was adopted, which opened quite a discussion among those interested in the subject. It was found that the dimensions presented in the 1912 U.S. Standard differed from the dimensions which had been quite universally used by manufacturers and which covered a large majority of the fittings made.

At a meeting of manufacturers held in New York City, July, 1912, a standard known as the Manufacturer's Standard was adopted by them. This left the flange fitting subject in the unfortunate position of there being two standards. When this condition came before the committee of the A.S.M.E., an effort was made by this committee with that of the manufacturers' committee to harmonize, if possible, the differences then existing between these two standards. After considering the various phases of the subject covering uniformity of design, strength of fitting, strength of bolting as well as the commercial features, a compromise was made. In this compromise the bolting was increased where it was thought necessary. Additional size flanges were added and the centre to face and face to face dimensions were altered to conform to these requirements.

The result is a new American standard for flanged fittings, standard and extra heavy pressures, adopted September 17th last by the committee of manufacturers on standardization of fittings and valves. It becomes effective January 1st, 1914. A pamphlet, "Flanges and Flange Fittings," published by the committee, has just been issued, covering the new regulations.

MARKET CONDITIONS

Montreal, October 4th, 1913.

Bar Iron and Steel—Trade is reported active. Bar iron, $2.10 per 100 pounds; best refined horseshoe, $2.35; forged iron $2.25; mild steel, $2.20; sleigh shoe steel, $2.20 for 1 x ⅜ base; tire steel, $2.30 for 1 x ⅜ base; toe caulk steel $3; machine steel, iron finish, $2.25.

Cement—Canadian cement is quotable, as follows, in car lots, f.o.b., Montreal:—$1.35 to $1 40 per 350-lb. bbl., in cotton bags, adding 10c. for each bag. Good bags re purchased at 10c. each. Paper bags cost 2½ cents extra, or 10c. per bbl. weight.

Chain—The market is quoted per 100 lbs. as follows:—¼-in., $5.65; 5/16-in. $4.70; ⅜-in., $4.00; 7/16-in., $3.65; ½-in., $3.45; 9/16-in., $3 45; ⅝-in., $3.35; ¾-in., $3.25; ⅞-in., $3 15; 1-in., $3.05.

Explosives and Accessories—Dynamite, 50-lb. cases, 40 per cent. proof, 15c. in single case lots. Montreal; 50 per cent., 16½c., and 60 per cent., 18c. Blasting powder, 25 lb. kegs, A, $1.85, and B, $2.35 per keg. Special quotations on large lots of dynamite and powder. Detonator caps, case lots, containing 5,000, 75c. per 100; double strength, $1, and broken lots higher; electric blasting apparatus:—Batteries, 1 to 10 holes, $13.50; 1 to 10 holes, $20.50; 1 to 50 holes, $41. Wire, leading, 1c. per foot; connecting, 50c. per lb. Fuses, platinum, single strength per 100 fuses:—4-ft. wires, $3; double strength, $3.50; 6-ft. wires, $3.54, and double, $4.04; 8-ft. wires, $4.08, and double, $4.58; 10-ft. wires, $5, and double, $5.12.

Galvanized Iron—The market is steady. Prices, basis, 28-gauge, are:—Queen's Head, $4.40; Colborne Crown, $4.20; Apollo, 10¾ oz., $4 30. Add 25c. per 100 lbs. to above figures for less than case lots; 26-gauge is 25c. less than 28-gauge, American 28-gauge and English 26 are equivalents, as are American 10¾ oz., and English 28-gauge.

Galvanized Pipe—(See Pipe, Wrought and Galvanized)

Iron.—Following prices are on dock. No. 1 Summerlee, $22.50 per ton; selected Summerlee, $22; soft Summerlee, $21.50 per ton. No. 3 Middlesboro irons are about $19 per ton. Carron iron number for number and grade for grade is quoted about the same price as Summerlee. Canadian iron sells here at about $19.25 to $19.50 per ton, on track.

Lath—See Lumber, etc.

Lumber, etc.—Prices on lumber are for car lots, to contractors, at mill points. Red pine mill culls out, $20 to $22 per 1,000 feet; white pine, mill culls, $20. Spruce, 1-in. by 4-in. to 6-in., $21; 1 x 7 to 9, $24 per 1,000 ft.; mill culls, $18. Hemlock log run, culls out, $19. Railway Ties, Standard Railway Ties, hemlock or cedar, 56 to 55c. each. Telegraph poles: seven-inch top, cedar poles, 25-ft. poles, $2, each; 30-ft., $3.75; 35-ft., $4.50 each; 40-ft., $6; 45 to 50, 16c. per foot. Laths: Quotations per 1,000 laths, at manufacturers' points. Spruce 4-ft. x 1½ in., mill run, $3 to $3.25; pine, 4-ft. x 1⅜-in., mill run, $3.25 to $3.75. Shingles: Cedar shingles, same conditions as laths, X, $2 10; XX, $2.40; XXX, $2.80.

Pipe—Cast Iron—The market is dull and rather easy:—$34 for 6 and 8-inch pipe and larger; $35 for 40-inch at the foundry. Pipe, specials, $3 per 100 pounds. Gas pipe is quoted at about $1 more than the above.

Pipe—Wrought and Galvanized—Demand is fair and the market steady: —¼-inch $5.50, with 63 per cent. off for black, and 48 per cent. off for galvanized; ⅜-inch, $5.50, with 63 per cent. off for black, and 48 per cent. off for galvanized; ½-inch, $8.50, with 69 per cent off for black, and 59 per cent. off for galvanized. The discount on the following is 72½ per cent. off for black, and 62½ per cent. off for galvanized; ¾-inch, $11.50; 1-inch, $16.50; 1¼-inch, $22.50; 1½-inch, $27. On the following the discount is 72½ per cent. for black and 62½ per cent. for galvanized:—2-inch, $36; 2½-inch, $57.50, and 3-inch $75.50; 72½ per cent. off for black, and 62½ per cent. off for galvanized: 3½-inch $95 4-inch, $1.08.

Toronto, October 8th, 1913.

The following are the wholesale prices for Toronto, where not otherwise explained, although for broken quantities higher prices are quoted:

Axes.—Standard makes, double bitted, $6 to $10; single bitted, per dozen, $7.50 to $9.

Bar Iron—$2.25 base, per 100 lbs., from stock to wholesale dealer. In enormous demand.

Bar Mild Steel—Per 100 lbs., $2.25. Sleigh shoe and other take same relative advance.

Boiler Plates—½-inch and heavier, $2.20. Boiler heads 25c. per 100 pounds advance on plate. Tank plate, 3-16-inch, $2.40 per 100 pounds.

Boiler Tubes—Orders continue active. Lap-welded, steel, 1¼-inch, 10c.; 1½-inch, 9c. per 10-ft.; 2-inch $8.50 to $9; 2¼-inch, $10; 2½-inch, $10.50; 3-inch, $12.10; 3½-inch, $15; 4-inch, $19.

Bricks—In active movement. The price is $11.50 for grey stock, $12 for red stock. Don Valley pressed brick are in request. No. 1 dry pressed and huff bricks are worth $18 delivered and $17 at works per 1,000. Port Credit Brick Company's prices are as follows, f.o.b., Port Credit: Wire cut bricks, $10 per M.; pressed bricks, $13 to $15 per M., three grades.

Broken Stone—Lime stone, good hard, for roadways or concrete, f.o b., quarries 70 to 75c. per ton of 2,000 lbs., either 1-inch, 10c., 2-inch, or larger, price all the same. Rubble stone, 55c. per ton, Schaw station, and a good deal moving. Broken granite is selling at $3 per ton for good Oshawa, nr Quehec Province. At Washago, $2.50 per ton for small, and $1.15 for large, freight to Toronto 60 cents.

Cement—Demand very brisk, and prices maintained. In large quantities the price is $1.50, sacks, 40c. extra; car lots $1.55, sacks extra; city dealers ask $1.85, sacks extra. Prices remain firm.

Copper Ingot—The market is lower at 15½ to 16c., sheet copper case (16 oz. soft), 22½c. to 24½c. per lb.

Detonator Caps—75c. and $1 per 100; case lots, 5,000, 20 per cent. off.

Dynamite—The prices for this explosive vary according to the percentage of nitro-glycerine compounded in the mixture and are as follows, f.o.b., Toronto: 40 per cent., 16½ cents per pound, 1 to 9-case lots, 50 lbs. to case. For each additional 10 per cent. nitro-glycerine add 1½c. per hundred. For 10 case lots and over deduct ½ cent. For 20-case lots and over deduct 1 cent. For 40-case lots and over deduct 1½ cents.

Fuses—Electric Blasting—Double strength, $3.50 per hundred, advance 54c. per hundred for each 2-in. wire additional. Single strength, $3 per hundred, advance 54c. per hundred for each 2-in. wire additional.

Iron Chain—¼-inch, $5.75; 5-16-inch, $5.15; ¾-inch, $4.15; 7-16-inch, $3.95; ½-inch, $3.75; 9-16-inch, $3.70; 5-8-inch, $3 55; ¾-inch, $3.45; ⅞-inch, $3.40; 1-inch, $3.40 per 100 lbs.

Iron Pipe—Quotations are changed as follows:—Black pipe, ¼-inch, $2.04; ⅜-inch, $2.04; ½-inch, $2.72; ¾-inch, $3.16; 1-inch, $4.54; 1¼-inch $6.19; 1½-inch, $7.43; 2-inch, $9.90; 2½-inch, $15.80; 3-inch, $20.75; 3½-inch, $26.13; 4-inch, $29.70; 5-inch, $40.60; 6-inch, $52.64. Galvanized Pipe, ¼-inch, $2.86; ⅜-inch, $2.86; ½-inch, $3.57; ¾-inch, $4.31; 1-inch, $6.19; 1¼-inch, $8.44; 1½-inch, $10.13; 2-inch, $13.50; 2½-inch, $21.56; 3-inch, $28.31.

Lead—Firmer, $5.25 to $5.50.

Pig Iron—We quote Clarence at $24 for No. 3; Cleveland, $24; Summerlee, $27; Hamilton quotes $22; Midland, No. 1, $22; No. 2, $21.50. There is considerable enquiry for 1912.

Pitch and Tar—Pitch, unchanged at 75c. per 100 lbs. Coal tar, $3.75 per barrel.

Roofing Slate—Most of the slate used in Canada comes from Pennsylvania or Maine, the Canadian supply being slender and mostly from the Rockland quarries of the Eastern Townships, in Quebec. There is a great variety of sizes and qualities, so that it is difficult to indicate prices But Jackson Bangor, 10 x 16 may be quoted at $6.75 per square of 100 square feet f.o.b. cars, Toronto; seconds, 50c. less. Mottled, $8; green $8, with a prospect of advance. Dealers are fairly busy.

Sand—Sharp, for cement or brick work, $1.15 per net yard f.o.b., cars, Toronto siding.

Sewer Pipe—

	4-in.	6-in.	9-in.	12-in.	24-in.
Straight pipe; per foot.....	$0 25	$0.40	$0.65	$1.00	$ 3.25
Single junction, 1 or 2 ft. long ...	1.00	1.60	2.60	4.00	13.00
Double junctions.....	1.25	2.00	3.25	5.00	16.25
Increasers and reducers.....	...	1.60	2.60	4.00	13.00
P. & H. traps	2.00	3.20	6.50	15.00	....
Bends	0.75	1.20	1.95	3.00	9.75

Above is the October list as changed. The retail price is less 65 per cent. off these figures on all sizes 9 inches and under, or less 60 per cent. off these figures on anything over 9 inches. For car-loads a greater discount.

Steel Beams and Channels—Active—We quote:—$2.65 to $3 cut to length per 100 lbs., according to size and quantity; angles, 1½ by 3-16 and larger, $2.50 to $2.75; tees, $2 75 to $3 per 100 lbs. Extra for smaller sizes of angles and tees.

Sheet Copper—22c. per lb.

Sheet Steel—American Bessemer, 10-gauge, $2.75; 12-gauge, $2.80; 14-gauge, $2.50; 17, 18, and 20-gauge, $2.75; 22 and 24-gauge, $2.80; 26-gauge, $2.85; 28-gauge, $3. A very active movement is reported at unchanged prices.

Sheets, Galvanized—Apollo Brand—Sheets, 6 or 8 feet long, 30 or 36 inches wide; 10-gauge, $3; 12-14-gauge, $3; 16, 18, 20, $3.30; 22-24, $3.40; 26, $3.50; 28, $3.90; 29, $4.10; 10¾, $4.10 per 100 lbs. Fleur de Lis—28-gauge, $4.25; 26, $4.05 per 100 lbs. Active and firm at these prices.

Tin—The combination seems to hold, and the price, 45 to 50c., lower.

Tool Steel—Jowett's special pink label, 10½c. Cammel-Laird, 16c. "H.R.D." high speed tool steel, 65c.

Tank Plates—3-16 inch, $2.40 per 100 lbs.

Zinc—Spelter—Good demand, and the feeling strong. Light stock; excellent demand. We quote very firm at $6 to $6.50 per cwt.

Winnipeg, October 7th, 1913.

Anvils—Per pound, 11½ to 12½c.; Buckworth anvils, 80 lbs. and up, 10¼ to 10¾c., anvil and vise combined, each $5.50.

Bar Iron—$2.50 base.

Bars—Crow, $4.50 per 100 pounds.

Beams and Channels—$3 to $3.10 per 100 up to 15-inch, 4, 30, 41, 50, 118, 119, 172, 132, 145, 176.

Brick—Kiln run per M, $13; sewer pipe per M, $14; chimney per M, $14; veneer per M, $15; pressed per M, $25 to $50; enameled per M, $100; sand lime per M, $13.

Cement, Portland—$2.40 to $2.50 per barrel.

Chain—Coil, 3-16-in., $10; ¼, $7.25; 5-16, $5.85; ⅜, $5; 7.16, $4.75; ½, $4.50; 9-16, $4.50; ⅝, $4.40; ¾, $4 25. Logging, 5-16, 6½c.; ⅜, 5¾c. Tie out, 70 and 10 per cent.

Copper—Tinned, boiler, 26½c., planished, 29½c.; boiler and T. K. pits, plain, tinned, 45 per cent. discount.

Dynamite—$11 to $13 per case.

Galvanized Iron—Apollo, 10¾, $4.80; 28, $4.60; 26, $4.20; 22, $4.10; 24, $4.10; 20 $4; 18 $3.95; 16, $3.90. Queen's Head, 28, $4.90; 26, $4.70; 24, $4.30; 22, $4.30; 20, $4.10 per cwt.

Iron—Swedish iron, 100 lbs., $4.75 base; sheet, black, 14 to 22 gauge, $3.75; 24-gauge, $3.90; 26-gauge, $4; 28-gauge, $4.10. Galvanized—American, 18 to 20-gauge, $4.40; 22 to 24-gauge, $4.65; 26 gauge, $4.65; 28-gauge, $4.90; 30-gauge, $5.15 per 100 lbs. Queen's Head, 22 to 24-gauge, $4.65; 26-gauge English, or 30-gauge American, $4.90; 30-gauge American $5.15; Fleur de Lis, 22 to 24-gauge, $4.50; 28-gauge American, $4.75; 30-gauge American, $5; bar, $2.50 base.

Pipe—Iron, black, per 100 feet, ¼-inch, $2.40; ⅜-inch, $2.55; ½-inch, $3.35; ¾-inch, $4; 1-inch, $5.75; 1¼-inch, $7 80; 1½-inch, $9.35, 2-inch, $12.50; galvanized—½-inch $4.35; ¾-inch, $5.20; 1-inch, $7.55; 1¼-inch, $10.25; 1½-inch, $12.25; 2-inch, $16.40. Lead, 7.60 per cent., full coil.

Pitch—Pine, $6.50 per barrel, in less than barrel lots, 4c. per lb.; roofing pitch, $1 per cwt.

Steel Plates, Rolled—3-16-in. $3.35 base; machinery, $3 base; share, $4 50 base; share crucible, $5.50; cast share steel, $7.50; toe caulk, $4.50 base; tire steel, $3 base; cast tool steel, lb., 9 to 12½c.

Tool Steel—8½ to 15c. per pound.

AN EXAMPLE OF DIFFICULT TUNNELING

THE COMBINED USE OF SHIELD AND COMPRESSED AIR ON WORK SUBJECTED TO UNUSUALLY COMPLEX CONDITIONS

By J. M. M. GREIG, A.M.I.C.E.
City Engineer's Department, Toronto

THE driving of a sewer tunnel under somewhat unusual circumstances arose in connection with one of the low-level intercepting sewers of the city of Glasgow. Starting from a shaft some 25 feet deep, the tunnel passed beneath the foundations of a very heavy retaining wall (clearing them by a foot or two) into running sand lying below an extensive freight yard bordering on the Queen's Dock. There were only 9 feet of cover between the top of the sewer and the rails, and at one point the centre line approached within 80 feet of the quay wall. To open-cut this section was out of the question owing to traffic conditions, and to drive a tunnel through quicksand with an unlimited supply of water close by was no light task.

It was decided that the tunnel should be driven with cast-iron segments, so as to minimize the ground opening; but, as the railway company had doubts as to the effect of their extremely heavy loads on the roof of the finished iron tunnel, a thick brickwork lining of these segments was insisted upon. This made the section one of great strength, but of an external diameter somewhat out of proportion with the inner diameter, as will be seen by reference to Fig. 1.

There were 420 linear feet of sewer immediately below the rails, and the ground throughout was clean sand, varying in fineness, and full of water.

Work Previous to Arrival of Shield.—A shaft was sunk, and from it the tunnel was driven, at first with cap-and-leg settings of timber and a brickwork lining. This did not prove a satisfactory method, the street showing signs of subsidence, owing, no doubt, to the exceedingly unstable condition of the bottom, rendering effective propping impossible. An attempt to tunnel with iron lining turned out equally unsuccessful, and, after the necessary plant had been put to work, a third trial was made with iron and compressed air.

About 30 feet of tunnel were driven thus under the deep cover of the street, but the openness of the ground and the large area of exposed face caused a great escape of air, little improvement being effected, therefore, in the conditions of the bottom. The air pressure gradually fell from 5 to 2 pds. per sq. in. as the tunnel approached the wall, and mining operations became exceedingly difficult toward the end, only one ring being built per day. It was evident from the disturbance of the surface that the miners were not holding the ground, and that the continuation of this method of tunneling beneath the retaining wall would be attended with great risks; so it was decided to try a shield.

Description of Shield.—The outer shell of the shield consisted of a cylinder of steel plates, the clear inside diameter being 8 ft. 8½ in. and the length over all 7 ft. 10 in. Inside this shell and about 2 ft. behind the cutting edge was a bulkhead or diaphragm formed of plates, stiffened with channels and angle gussets off the front upper portion of the shell, called the hood. This diaphragm had two openings, 1 ft. 7 in. by 4 ft. 8 in., separated by an I-beam in the centre, which, with the side channels, formed two sets of grooves, into which stop-planks might be placed, should it be necessary to close the face or reduce its area. Besides these working openings there were two small hand-holes in the lowest part of the diaphragm through which the sand was forced as the shield drove forward. In very bad ground a great amount of the excavation might have been taken out through them with the larger openings closed.

Below springer level the cutting edge receded from 2 ft. to 4 in. off the diaphragm; thus there was a hood above that portion of the ground being excavated, while it was still possible to reach the ground immediately in front of the lower portion of the cutting edge and so clear the way for the bottom of the shield, thus obviating the possibility of boulders damaging the cutting edge. The hood was stiffened with an additional plate, so that the cutting edge was really formed by the bevelled edges of three plates above springer, and of two below.

Behind the diaphragm there was a cast-iron ring formed of six flanged segments fixed to the shell by taps, while screws running through casting and shell held the ram castings in position. The rams, six in number, arranged symmetrically around the circle, were 4 in. in diameter, and had a maximum travel of nearly 2 ft. There was a sufficient length of shell (8 ft. 8½ in., inside diameter) behind the segments to admit of one ring being erected inside the tail of the shield with about 6 in. of the shell overlapping the iron already erected.

The main hydraulic feed-pipe was fixed to the shield on one side, about springer level, and from it the high-pressure water was separately distributed through smaller pipes to each ram, small valves on these pipes giving independent control of each ram. Thus the shield consisted of a steel shell divided into three portions—the hood with the cutting edge, underneath which the excavation was taken out, the body containing the means of propulsion, and the tail, in which the tunnel rings were built.

To obtain the necessary hydraulic pressure an air-compressor on the surface supplied an air-engine or

pump in the tunnel. This pump was fixed in the side of the tunnel, near the face, and from it wrought-iron piping, with a flexible end-piece, carried the high-pressure water to the receiver on the shield, and a similar arrangement of pipes returned the exhaust water to a small tank below the pump. The whole mechanism was most compact, tank and pump occupying a space of less than 8 x 2 x 4 ft.

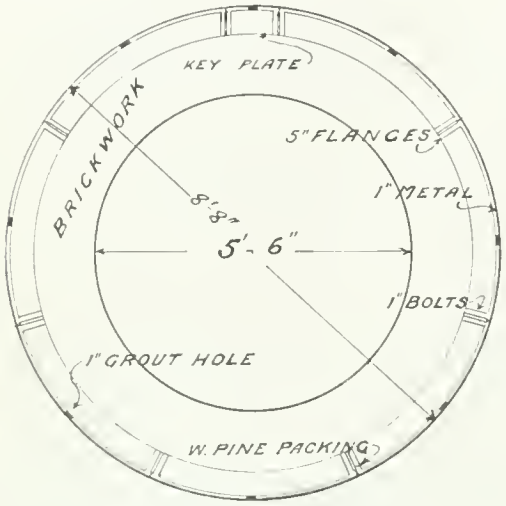

Fig. 1—Section of Sewer.

Erection of Shield.—As the use of a shield had not been contemplated in the original layout, the erection of this shield was carried out, not in a shaft as is usual, but in a specially excavated chamber in the tunnel, which was enlarged for a short distance to a diameter of 11 ft. This shield chamber might have been excavated ahead of the iron had it not been that the face was already very near to the wall; but in any case, it was probably safer to excavate around the outside of the iron—from which temporary propping could be erected—rather than to open up new ground.

In the last length of eight rings, seven were taken out, the eighth being left as a rib to support the longitudinal bars used in poling back. Two plates were broken to obtain an opening in the lining, and the key-plates of the unbroken rings were taken out first, the upper plates being supported by struts from the invert. A crown bar was put in through the lagspace and carried on short props from the leading and ninth rings. The upper plates were next taken out, those along one side at a time, and the ground poled back on bars similarly supported. Below springer the excavation was taken down and timbered outside the rings as far as possible before the removal of the plates.

All this temporary timbering had cement grout under pressure forced into the ground behind it. The bars were then sheeted inside, and the space was pressure-grouted. By this means the top was made practically air-tight, and a fairly good pressure maintained while the bottom was being excavated and poled with 3-in. sheeting.

The shell was taken into the tunnel in pieces and erected round the framework of the bulkhead. The taps fixing the cover-plates to the shell were cut and hammered flush with the inside face to allow the tunnel segments to fit closely. The body segments were also attached to the shell by means of screw taps. Bolts with counter-sunk heads held the angle-stiffeners to the shell and the bulkhead; thus the only variation from a smooth outside surface was the longitudinal cover-plates. A cradle of half-timbers supported the shield at its proper level, and on the completion of erection, the space between shell and walls of chamber was packed with dry brick and grouted with cement under pressure. There was now a set of crown bars held by the shield, forming cantilevers in support of the ground above the leading ring, which was taken down and the shield driven hard to the old face polings. These were bored out in small parts and clay put into pockets excavated ahead around the cutting edge of the shield, new face-boards being put in horizontally to form a circular shutter of timber about 2 ft. less in diameter than the cutting edge, as shown in Fig. 2.

Method of Excavating.—As a rule, the shield was driven forward until the diaphragm was within about 10 in. of the horizontal face poling-boards, these boards being supported during the period of movement by two raking struts off a cross-piece on the second last ring, and butting against two vertical soldiers running across the boards. Fig. 3 shows the shield ready to move ahead, and Fig. 4 shows excavation in progress. When the shield came to rest each poling-board was strutted off the diaphragm with short blocks and wedges. With the face thus supported the rakers and soldiers were taken down and excavation proceeded with by withdrawing the top poling and pulling out the sand with hand-tools.

A pocket or groove was cut out a little beyond and above the cutting edge, and clay rammed in, after which the first poling-board was carried forward and re-erected against the new face with long struts off the diaphragm. In this way each board in turn was carried forward and the face kept continually poled up. Below the lowest board the sand was roughly excavated down almost to the cutting edge, and, after erecting the rakers and soldiers, the struts were removed, leaving the shield again in position to travel ahead. The excavated sand was thrown upon a staging at the level of the sill of the openings, from which it was shovelled into wagons and taken through the air-locks to the shaft.

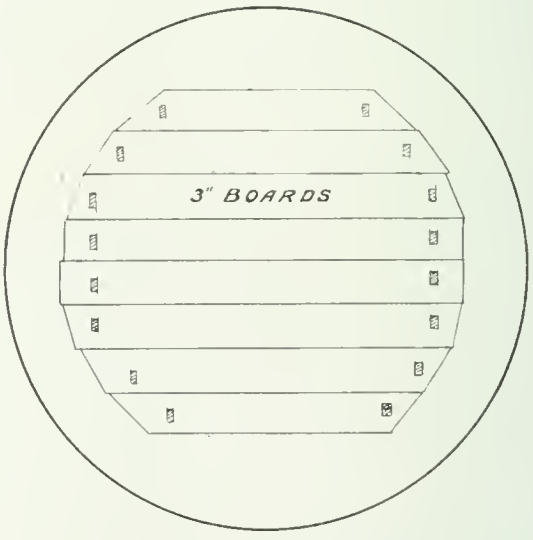

Fig. 2—Poling of Face.

In this ground the shield showed a decided tendency to go downward while in movement, but it was kept to proper level by using the 3 lower rams only during the first part of the movement. After the cutting edge was fairly buried the two upper side rams were brought into action as the first three did not give a force sufficient to drive the shield ahead. During the first period, with three 4-in. diameter rams working under a pressure of 1,500 to 1,600 pds. per sq. in., the total effort was about

24 tons, or 280 lbs. per sq. ft. of skin surface. When the cutting edge was buried the resistance was more than that due to mere skin friction, and, after applying 5 rams and increasing the pressure per sq. in., the total effort rose to about 48 tons. The highest pressure used was 1,900 pds. per sq. in., or a total push of nearly

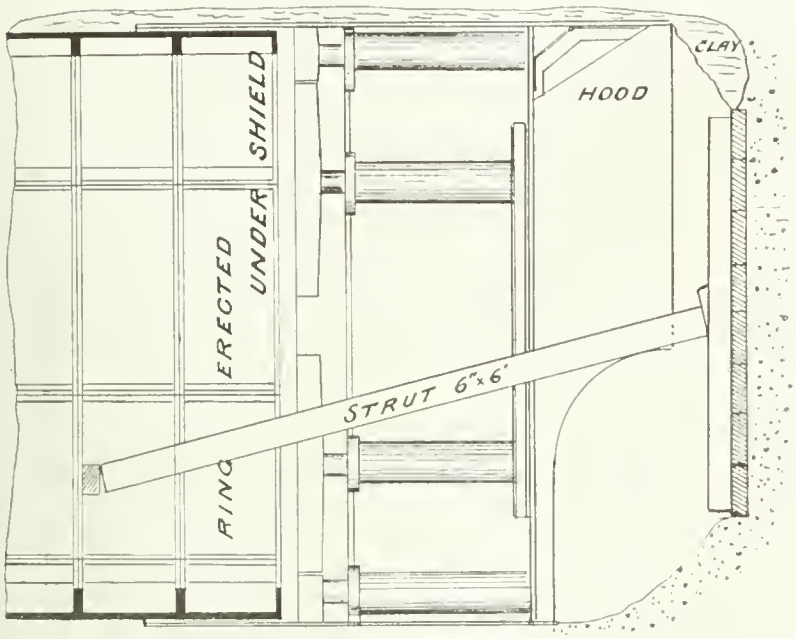

Fig. 3—Longitudinal Section of Shield—Excavation Completed.

60 tons. The average time of travel was 8 minutes in all. Though the air pressure kept the upper portion of the face dry, the bottom was always very wet, but, as it was exposed for a short time only, the water did little harm.

Immediately after the shield had been driven ahead the last ring was grouted with cement under pressure of 40 to 50 pds. per sq. in. Cement grout was used for the lowest plate, but lime grout for the upper portion of the tunnel, where the air pressure kept back the water. There was no escape for this pressure grout at the shield, since wooden buffer ribs, held firmly against the flange of the last ring by the rams, closed any opening between them and the skin. The next ring of iron tunnel lining was not erected until the whole face had been excavated and everything was ready to drive ahead, so the buffer ribs remained sufficiently long enough in position to permit of the mortar partly setting. Five pounds was about the maximum air pressure in the tunnel while beneath the deep cover, but on leaving this it fell to between 2 and 3 pounds, and sometimes less, partly due to slight leakage at the joints over some 50 or 60 yds. of unlined ironwork then exposed.

Grummets of string dipped in red lead and placed around the bolts beneath the washers proved effective in stopping leakage at bolt-holes. All joints had been plastered over with neat cement, previous to the adoption of red lead on grummets, but, as air continued to escape at the bolt-holes, the shield was stopped and brickwork built from the air-locks nearly up to the face, completely sealing the tunnel behind the shield.

Previous to this point no cement had been used for grouting the lower plate but with its use and the brickwork lining carried forward, another pound of pressure was obtained, making mining operations much easier. This slight increase in pressure probably allowed the grout to more completely encase the iron, for there was very little leakage through unlined ironwork from this point forward.

Mechanical Plant.—While under the deeper cover the air pressure averaged about 5 pds. per sq. in., with the engine running at 60 R.P.M., under 110 pds. of steam; and, in the lighter cover, 2½ pds. air pressure, with the engine running at 70 R.P.M., under the same steam pressure. A "Larmuth" compressor, with steam cylinder of 16-in. diameter and 24-in. stroke, coupled direct to a 15-in. diameter air pump, supplied air to the tunnel. The number of men on each shift was 3 miners and 4 laborers, excavating, setting segments and pressure grouting, with a locksman and two enginemen, 11 in all.

Points in the Use of Compressed Air.—The principal point of escape for the air was undoubtedly the working face, though this was kept as closely poled as possible. When the face was completely closed up and grouted, during the period when the brick lining was being brought up to the shield, the same working air pressure could be maintained with the engine running about half speed. This illustrates one of the many advantages of using a shield, as, even with the comparatively simple shield here described, it was possible to reduce the area through which air might escape to a few square feet of sand, and with more complicated mechanism, still greater control might be exercised over the area of escape. In placing the poling boards against the face it was usual to smear their edges with clay. A neat illustration of the course taken by the air could be obtained

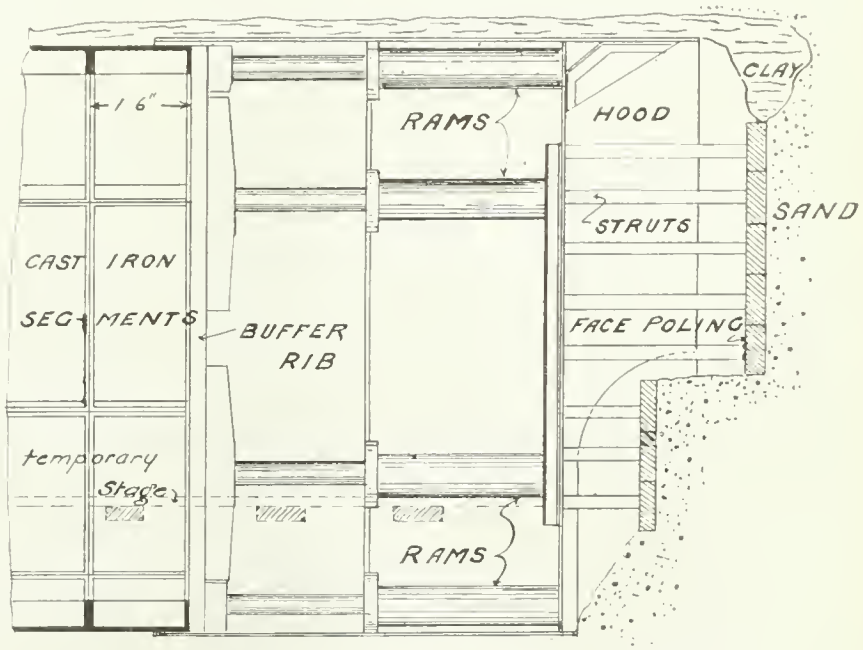

Fig. 4—Longitudinal Section of Shield—Excavation in Progress.

by removing a piece of this clay and holding a candle to the spot, when the flame would be drawn into the joint and extinguished. If the ground is very open compressed air alone may be of little use, especially under light cover, but with it in combination with a shield the most unstable ground can be negotiated.

Compressed air will travel great distances through open ground, and may set up quite unexpected disturbances, as, for instance, by getting into old, leaky sewers. It is never advisable to use a greater pressure of air than that which is just sufficient to balance the weight of water head. The writer has known of the waters of a pond being disturbed by compressed air from a tunnel more than half a mile away. In grouting with 30 or 40 pds. pressure it is quite a common thing to find the cement driven up to the concrete of the roadway from a depth of 20 feet, where pits had been sunk or previous excavation carried out. Of course, the shield has been used much in tunneling without compressed air, and it is a most useful mechanism, which might be more popular with contractors were it not that it has been so much associated with very difficult and expensive tunnels, such as the portion of sewer which is the subject of this article. Though the shield in this case was a costly piece of plant, its use was justified by the safety in which the work was carried out, the excellent progress made amounting to 42 feet per week.

CEMENT IN EGYPT.

The Bulletin Commercial, of Brussels, states that Egypt now offers an important market for cement. In 1911 the imports were 106,670 tons, valued at $800,000, as compared with 87,503 tons in 1910. The great vogue for buildings of ferro-concrete has largely contributed to the remarkable development of the import trade in cement, and this trade seems quite likely to be maintained, in view of the attention which is being given by capitalists to the building industry. The extensive port works recently commenced at Port Said, and those projected at Alexandria, will necessitate the provision of large quantities of cement. The Belgian imports were the largest in 1911, amounting to 50,257 tons, followed by those from England, 35,192 tons. The remainder of the imports came from Austria, France, and Germany. Artificial cement (slow hardening) is imported in barrels of 150, 180, and 200 kilos. gross for net. Sacks are taking the place of barrels owing to the rapidity with which the cement is used. There are, however, cases where barrels are preferred. Natural cement (rapid or semi-slow hardening) is used principally by the natives and also for certain masonry work. It comes mainly from Belgium and is imported in barrels of 140 to 150 kilos. gross for net, and in sacks of 45 to 50 kilos., sacks invoiced. The question of sacks sometimes presents difficulties for the importer. Empty sacks are invoiced to him by the manufactory; if he takes care of them, or returns them only in a bad condition, they are carried to his account. Cement users, however, do not readily agree to these conditions, and the importer eventually suffers the loss. English manufacturers are in the habit of shipping cement in very light bags, which are strong enough for one voyage and for which there is no charge. This method has given excellent results.

The Commission of Conservation, Canada, has prepared a summary of rail production in Canada from 1895 to the beginning of the present year. The increase shown in the intervening years has been from 600 to 423,885 tons.

TRAFFIC CENSUS IN MASSACHUSETTS.

A summary of that portion dealing with the construction and maintenance of roads, of the Massachusetts Highway Commission's report for the year ending November 30th, 1912, was given in October 9th issue of *The Canadian Engineer*. There are a few points in connection with the traffic census outlined in the report, that are of great interest, inasmuch as it is of such importance to have an accurate knowledge of the traffic which any particular road has to carry. As the Commission states "The road must be so designed, built and maintained that it shall be at all times in proper condition to bear the traffic to which it may be subjected, and not only at the least cost to the user, but also at the least ultimate cost to the taxpayers, taking everything into account, viz., interest, sinking fund, yearly maintenance and occasional resurfacing. Without a knowledge of traffic one is really entirely at sea. The road builder is likely to make serious and costly errors by determining upon the wrong kind of construction and by selecting improper or unsuitable materials or methods."

The Massachusetts Highway Commission in 1909 had a census taken upon the State highways at 238 stations, scattered throughout the State; and in 1912 a similar traffic count made at 156 stations.

While the count in 1912 was taken at fewer points than in 1909, it was felt that the percentages of increase and decrease could safely be used to indicate the traffic on other similar roads.

A traffic census was also taken at the same time at quite a number of points around the city of Boston on roadways in the metropolitan and Boston park systems.

The census was made in the following manner: The vehicles actually passing on the road were counted by observers, who were engaged for the purpose. All vehicles were counted for fourteen hours a day (7 a.m. to 9 p.m.) for seven consecutive days in August, 1909, and again for seven days in October, 1909, at 238 stations, the daily census at each station being tabulated on a card. This same census was made again for like periods of time in August and October of this year (1912). At a few important points a count was also made at night, the census at these places covering the whole twenty-four hours.

After the cards were received the number of vehicles observed at each point was tabulated and computed to show the average number of each class of vehicle passing the given point per day, the total number of vehicles and the total of each class, both motor and horse-drawn. When these figures were obtained the percentage of each class of vehicle using the particular road was computed, and the percentage of the total of each class at all stations was computed as well. After these averages were computed for each of the 238 stations in 1909 and for the 156 stations in 1912, the total average number of vehicles at all the various stations was added, the numbers ascertained, and from this was obtained the average number of vehicles passing each day at all the points where the count was made, as well as the average number of each class and kind, and the percentage that the vehicles of each class bore to the average total number.

The increases and changes in traffic from 1909 to 1912 are shown in Table I., which, by the way, shows that the traffic is changing much more rapidly than it is increasing. The figures represent a count taken in 1909 and 1912 for fourteen days of each year, and from 7 a.m. to 9 p.m. of each day. The report goes on to say that the significant feature of the census for the roadman is not the increase of traffic, but the change in the traffic.

It is that which he must consider and for which he must prepare. Another factor which further analysis brings out, and which is also important, is that light, single-horse vehicles decreased 25 per cent.; two-horse vehicles, 14 per cent.; heavy, single-horse vehicles, only 3 per cent., and heavy two or more horse vehicles, only 5 per cent.

Table I.—Increases and Changes in Traffic from 1909 to 1912.

	1909 Census, 238.5 Stations			1912 Census, 156.5 Stations

Weight of Traffic.—In commenting upon the weight of traffic as an important consideration, the report states:—

"After all, it is not numbers which tell the story, it is weight, and it is not weight alone, but the vehicle by which it is transported, whether by horses or by motor. It is not the tractive power alone that makes the difference, but the tires which support the vehicle; whether iron or rubber comes in contact with the road; whether the vehicle is pulled over the road or propels itself, and thus pulls upon the road surface. All of these considerations are probably not so important on many road surfaces as the actual weight imposed upon the road per inch width of tire resting upon the road.

"In other words, heavy loads supported upon narrow iron tires, having a weight of over 600 to 800 pounds for each inch in width of the tire, do vastly more damage to most, if not all of our roads than do very much heavier loads where the weight per inch width of tire is less.

"Such loads carried on such narrow tires will practically destroy any road surface, except a pavement, in a few months if there are many such vehicles using the road every day.

"After careful study they have adopted in England an assumed weight, or coefficient, for each kind of vehicle using the roads, in order to make a fair comparison of the traffic upon different roads where the traffic varies, and to more nearly show what the road must support. It is quite similar to the formula in use in France and on the Continent.

"It is, therefore, used both for want of a better one, and also because it gives a fair basis of comparison. Table II. shows the weight of the road traffic on Massachusetts roads computed in this way, with the coefficient reduced to tons of 2,000 pounds each in every case, both on the English and Massachusetts roads:—

"Here, again, not only are the changes in traffic notable, but the weights are even more important.

"The average weight per station per day of the motor vehicles in 1909 was 197 tons; in 1912 it was 512 tons. For horse-drawn vehicles it was 147 tons in 1909 and only 135 tons a day in 1912.

Table II.—Weight of Traffic on Massachusetts Roads.

	1909			1912		
	Average Number per Day per Station	Assumed Weight (tons)	Weight per Day per Station (tons)	Average Number per Day per Station	Assumed Weight (tons)	Weight per Day per Station (tons)
Motors:—						
Runabouts	20.8	1.43	29.7	37.2	1.43	53.2
Touring cars	75.3	2.23	167.9	173.5	2.23	386.9
Trucks	—	6.25	—	11.5	6.25	71.9
Totals	96.1	—	197.6	222.2	—	512.0
Horse-drawn vehicles:—						
One horse, light	71.5	.36	25.7	52.5	.36	19 3
One horse, heavy	49.3	1.12	55 2	47.6	1.12	53.3
Two or more horses, light	4.2	.54	2.3	3.6	.54	1.9
Two or more horses, heavy	26.0	2.46	64.0	24.7	2.46	60.8
Totals	151.0	—	147.2	129.4	—	135.3
Totals of all kinds	247.1	—	344.8	351.6	—	647.3

"The weight of automobile traffic has increased 160 per cent. in three years, while the weight of horse-drawn vehicles has actually decreased 8 per cent. in the same time. While this is true, note what happened: the motor truck has come in with an average number of trucks of 11½ per station, and their weight is nearly 72 tons a day. The weight of teams decreased 12 tons a day; trucks came in with a weight of 72 tons a day, making good the loss in team weight six times over."

The width of roadway is also given due consideration, as it is manifest that what wears out a road is the actual weight and volume of traffic that has to be sustained by each inch in the width of the road surface. The report contains tables showing the assumed actual weight in tons, per day, passing over each yard in width of the macadam roadway on certain roads in Massachusetts.

Table III.—Average Daily Traffic.

	Light Teams	Heavy Teams, One Horse	Heavy Teams, Two or More Horses	Automobiles a Day
A good gravel road will wear reasonably well and be economical with	50 to 75	25 to 30	10 to 12	100 to 150
Needs to be oiled with	—	—	—	Over 150
Oiled gravel fairly good either hot or heavy cold oil ½ gallon coating (cold oil must be used yearly)	75 to 100	30 to 50	20	500 to 700
Water-bound macadam will stand with	175 to 200	175 to 200	60 to 80[1]	—[2]
Dust-layer will prove serviceable on such macadam with	—	—	—	50 to 100
Macadam will then stand (but the stone wears, of course) with	—	—	—	300 to 500
Water-bound macadam with hot oil blanket coat will be economical with[3]	150 to 200	75 to 100	25 to 30	Up to 1,400
Will stand at least[5]	—	—	—	—
But will crumble and perhaps fall with over	—	100[6]	50[6]	—

[1] Perhaps more.
[2] Not over 75 at high speed.
[3] The large number of automobiles seems to keep the oil rolled down when it would be cut up and crumble without this traffic. Water-bound macadam with a good surface coating of tar will stand a very large number of automobiles, but the commission has not used tar extensively as a surface treatment where there is heavy team travel.
[4] And more with fewer teams.
[5] Fifty motor trucks, probably more.
[6] On narrow tires; or loaded farm wagons, ice and wood teams, etc.

The Commission emphasizes the necessity of a traffic study for the purpose of helping the road engineer determine the type of road to build, and the best method of maintenance. The experience in Massachusetts and elsewhere has shown conclusively that large numbers of swiftly moving automobiles cannot successfully be carried over a water-bound macadam road or over a gravel road. Such a road becomes ravelled very rapidly, rutted and disintegrated. Traffic studies indicate that from 50 to 100 automobiles a day make the use of some dust-layer or binder necessary, and its use would possibly prove economical on a road where there is even less motor

traffic. With the motor traffic which Massachusetts already has it has been found necessary, both for economy and for efficiency, where a road has heavy team traffic as well, to adopt in construction or resurfacing some form of bituminous mixture for the upper two or three inches of the road surface, at least, or some stronger road, like concrete. In many places, the Commission believes, such construction or reconstruction, has been, and will be, economical.

Conclusions Summarized.—A table has been included in the report showing as nearly as may be the results which have been observed after four years of experience with bituminous materials, comparing these results with the traffic going over the road in 1909 and again in 1912. The Commission realizes fully that more experience will undoubtedly cause it to change or modify some of its present opinions, but they are submitted for what they are worth as indicating the result of its experience in Massachusetts.

The standard road is 15 feet in width of macadam, with three-foot gravel shoulder on each side.

RESISTANCE OF THICK CYLINDERS TO RUPTURE.

According to M. Malaval, in "Rev. de Metallurgie," in a tube of the proportions of gun practice, the thickness about equal to the calibre, there are two distinct periods besides the elastic range. This is followed by the range of semi-elasticity or partial failure, which is of sensibly the same duration in stress. With increasing applied pressures the area of overstressed metal widens radially outwards. Thus if the pressure is released the outer elastic zone is prevented from returning completely to its original shape by the permanent deformation of the inner plastic zone. The mutual action causes the unloaded tube to be stressed in tension in the outer region and in compression in the inner, so that it is in the condition of an ideal shrunk composite tube—i.e., one with an infinite number of indefinitely thin components whose mutual pressures are such that under rising internal pressure all parts reach the elastic limit simultaneously and bear equal parts of the load. The semi-elastic period ceases when the outside layer reaches the limit of elastic deformation and is followed by the periods of general failure. During this period, covering an increase of resistance much greater than those of the first two periods, all parts show an increase of resistance, the inner region being in compression and the outer in tension. It follows that the metal, whose capacity for deformation is greater in compression than in tension, can withstand very considerable internal strains. It is concluded that the ordinary shrinking process might be replaced advantageously by one involving initial overstraining of a solid tube. A gun so constructed would withstand a pressure of over 1,500 kilogrammes per square centimetre (213,300 pounds per square inch).

The statistics of the report of Mr. J. McLeish on Economic Minerals and Mining Industries of Canada, contains the following record of production of pig iron:—In Ontario, in 1911, 526,635 tons valued at $7,606,939, in 1912, 589,593 tons valued at $8,176,080; in New Brunswick in 1911, 31,120 tons valued at $69,464, in 1912, 71,520 tons valued at $127,716; in Nova Scotia, in 1911, 390,242 tons valued at $4,682,904, in 1912, 424,994 tons valued at $6,374,910; in Canada, in 1911, 917,535 tons at a value of $12,307,125, while in 1912 an increase is shown in the production of 1,014,587 tons at a value of $14,550,999.

LIQUID, SOLID, AND GASEOUS FUELS FOR POWER PRODUCTION.

IN a paper presented a month ago to the Engineering Section of the British Association, by Prof. F. W. Burstall, of the University of Birmingham, the means by which carbonaceous substances might be treated to render them suitable for the production of power were touched upon. The address has just appeared in extracted form in *The Iron and Coal Trades Review*, and is reproduced herewith:—

The fuel of the world, he said, consisted of two forms—liquid and solid, both of which were closely related inasmuch as they consisted of compounds of carbon and hydrogen, together with small percentages of other substances, such as nitrogen. Most engineers looked upon coal purely from the point of view of fuel to be used in a furnace for the production of heat. It was, however, a complicated substance from which could be extracted a wide range of valuable products.

There were points in the use of gaseous fuel which led to serious difficulties. In order to secure efficiency the main mass of the air must be heated by compression before the principal heat supply was added. The combustible gas might be added before compression began, as in the well-known Otto cycle, but this introduced the possibility of the charge igniting before the correct time. It also required that the gas should be free from any liquid or solid substances, a state of affairs not easy to obtain on a large scale. If the gas were compressed in a separate pump there was a certain loss of heat due to necessary cooling of the pump. With a liquid fuel there was no difficulty in forcing the small amount of oil required into the pre-heated air, and the oil was readily freed from foreign matter; also, there did not appear to be any inherent reason why the oil engine should not be made in the largest sizes, beyond those of weight and cost, where it must always be inferior to the rotary machine.

Passing on to deal with the gas turbine, Prof. Burstall said it could readily be shown that the velocities which had to be dealt with were no greater than those encountered in the steam engine, but there were difficulties which, in spite of innumerable efforts, had so far proved insurmountable. The greatest defect was that, so far, it had not been found feasible to compress the air and gas in the turbine itself. Separate compression considerably increased the losses, so that in place of the negative work being one-third of the gross work it would probably be at least one-half. and perhaps more. The cooling of the rotating disc and blades offered difficulties, and further, no material had been found so far that would withstand the erosive effect of the burning gases. It seemed very doubtful if the gas turbine could be constructed to compete with the reciprocator in the present state of knowledge.

It was important to consider the amount of various fuels raised in various parts of the world. At present about 1,200,000,000 tons of coal of various kinds were brought to the surface every year; crude oil amounted to about 50,000,000 tons per year, and it was doubtful if there were any large oil fields yet to be discovered. It, therefore, followed that the supply of oil was totally inadequate in amount to replace coal for power production on a scale equal to the present steam-power production. The artificial production of oil was at present being considered seriously by engineers, and much yet remained to be discovered in this field. Every engineer was familiar with the fact that when coal was heated in a closed retort gas and tar were given off, and also that the higher the

temperature at which gasification took place, the greater was the yield of gas and the smaller was the amount of tar formed.

Up to the present coal had been gasified with the object of obtaining the highest yield of gas, but it was quite possible to alter the conditions of carbonization so as to obtain a high yield of fuel oils and other compounds of value as by-products, and an important one was sulphate of ammonia, the use of which as a manure was steadily increasing in all countries of the world. Sulphate of ammonia was the most valuable manure where nitrogen was needed, and it was one of the greatest defects of the crude burning of coal that such enormous amounts of nitrogen were not only wasted, but turned into nitric acid in the atmosphere. Of course, the nitric acid was returned to the soil by the agency of rain, but not necessarily where required by the cultivator.

For one ton of coal gasified in a modern gasworks 11,500 to 12,500 cub. ft. of gas were obtained having a calorific value of about 550 B.T.U. per cub. ft., and also about ten gallons of tar and 25 to 30 lbs. of sulphate of ammonia. The gas had to be purified for domestic purposes; also a gasworks had to be near a great town where the working expenses were not so low as in a more rural part. For these reasons it was doubtful if town gas could be supplied under present conditions for much under 10d. per thousand cub. ft. Despite these facts, Prof. Burstall said he held the opinion after mature consideration, that the whole problem of fuel treatment would lie in the direction of heating the coal, peat or lignite in a closed retort; not necessarily under the conditions which were at present forced on to the gasworks, where the primary object was to produce a big yield of gas of a certain standard as laid down by Parliament. If it be granted that the quantity, quality and purity of the gas produced were a secondary matter, the problem of fuel treatment became one of the most fascinating problems which the engineer could encounter. It had long been known that the quantity and quality of the tar was largely influenced by the temperature at which the fuel was carbonized, the lower the temperature the better were the tars in both yield and composition. The amount of sulphate of ammonia recovered from the gas was only some 25 to 30 lbs. per ton of coal, whereas the amount of nitrogen present in the coal would give about 120 lbs. of sulphate of ammonia. In the ordinary process of carbonization some three-quarters of the nitrogen was left behind in the coke. Under present conditions this could not be avoided, but improvements in this direction were possible. If the gas and tar were withdrawn from the heat directly they were evolved from the coal, a set of products would be obtained of a different composition from those usually obtained.

Prof. Burstall then outlined a scheme of fuel treatment which he admitted was at present wholly beyond the region of practical realization. The first step was to obtain a coal field of wide extent yielding a coking coal, the essential point being to obtain a sufficient supply of coal to enable the capital charge to be repaid in a series of years—probably thirty. The works would have to be on a large scale to economize cost of working, but the carbonization plant would be placed near the pit-head, so that the tubs could discharge direct into the bunkers of the retort-charging machines. A convenient size for each plant would be about 2,000 tons per day, and there would be some five to six pits operating over quite a large area. There would be no gain from any point of view in not shipping the coke and sulphate of ammonia direct from the pit-head, as these would be ready for market without further treatment. Tar and gas would be taken by pipe lines to suitable points for their future treatment, depending upon geographical considerations. The tar from the whole of the works would be passed through continuous and automatic stills, where the various fractions would be obtained with the least expense. The fractions, after working with acid and soda, would pass to a second set of automatic stills, this process being continued until the pure produces ready for market were obtained without the necessity for storage and in the least possible time. As to how far the treatment of residuals should be carried, no definite answer could be given, as it depended on the current prices, but on the scale considered, viz., 120,000 to 140,000 gallons of tar per day, it would certainly be advantageous to treat the products to a finish.

That portion of the gas not required for firing the automatic stills and for colliery purposes generally would be led to a different point, perhaps many miles from the pit-head. This offered no difficulty as regards the power required, the great obstacle being the cost of the pipe line, which might to a large extent be reduced by gasholders at the delivery end so as to improve the load factor on the pipe line. The gas would be free from tar, but would contain the sulphur compounds, and would be employed in gas engines for the generation of electricity at high voltages.

No doubt electrical engineers would look askance at gas engines, not only from the many failures that had occurred with some of the large engines, but also at the fact that at present some 2,000 h.p. was about the largest size that could be built, whereas a steam turbine could be constructed to give an output of 20,000 kw. at a low first cost. The gas engine could only compete with the steam turbine when its gas was delivered to it at a price which, when helped by its high thermal efficiency, would enable it to recoup its large capital outlay. But perfect as was the steam turbine as a mechanical machine, its thermal efficiency was half that of its rival, as the cost of the steam delivered to it could not be reduced. There were also no by-products. For these reasons it was quite possible for the gas engine to produce current more cheaply than the turbine, but the price of gas of a calorific value of 500 B.T.U. per cub. ft. would have to be 4d. per thousand cub. ft. if coal be taken at 20s. per ton. This would give for each fuel about 125,000 B.T.U. per penny, and taking the gas engine as 2½ times as efficient as a turbine, this should leave enough margin to compensate for the increased capital outlay. The exhaust gases would be washed so as to extract the sulphuric acid, which would be returned to the pit-head in the manufacture of sulphate and the washing of the tars, so that the only external material to be purchased would be the soda ash used to neutralize the excess acid. In this manner the whole of the products of the coal would be recovered in a form ready for the market, and if the coke were used as a domestic fuel a smoke-laden atmosphere would be impossible.

Producer gas for power and heating purposes had a large field in front of it, particularly when the factory was distant from the coal fields, and also where there was a steady load. In producer gas the whole of the fuel was converted into gas and tar, so that a large quantity of gas—120,000 to 140,000 cub. ft.—could be obtained per ton of coal. The ammonia yield was very high, being 80 to 90 lbs. of sulphate per ton; the calorific value of the gas was low, about 140 B.T.U. per cub. ft., and the tar was small in quantity and poor in quality, as it was nearly all pitch. The low calorific value and the difficulty of cleaning the gas were serious drawbacks to the transmission over long distances. In South Staffordshire, how-

ever, producer gas had been piped over a wide area for several years, and the undertaking now appeared to be on sound financial ground. The suction producer working on coke or anthracite coal had a very definite position for small plants in remote districts, where it formed a cheap and reliable source of power.

Taking the question of producer gas as a whole, it looked as though it would always have a definite use, but only a limited application, more especially in a country like Great Britain, where in time it would be possible in most parts to obtain electricity cheaply in bulk, and when this was the case no other source of power need be considered.

The case of coke ovens readily fell into the same class as the retorted gas, the only difference being that to obtain coke capable of carrying the weight of the iron in the blast furnace, the temperature of carbonization must be high—1,200 deg. C., and the period long—24 to 30 hour; thus the tars were poorer from being more split up, and the cost of repairs to the ovens was considerably higher than on a gasworks retort. As hard coke must be made, the place for it was in conjunction with the ordinary plant, so that the by-products might be readily worked up.

Discussion.—Mr. W. M. Mordey said that Prof. Burstall had held out little hope that the gas turbine would be a practical tool in the near future, but there was one solution which occurred to him, viz., the adaptation of the Humphrey gas pump with a water turbine, allowing the water to drive a dynamo. The overall efficiency of the Humphrey pump in water horse-power was said to be something like 30 per cent., which was very high, and if the pump could be used in conjunction with a water turbine which had an efficiency of about 85 per cent., an overall efficiency of the combined pump and turbine of 25 per cent. would be obtained. Such a solution would very much simplify the problems now presented by the gas turbine and provide at the same time a direct means of driving a dynamo by a simple rotating motor. This method would give an efficiency as high as any large gas engine would give in continuous work in a much more simple manner.

Dr. J. S. Owens, dealing with the suggestion of the carbonization of coal at high temperature in order to get all the possible by-products, said that this produced a coke which was unsuitable for domestic use. Coke would not burn well unless there were a certain amount of volatile matter left in it, and such coke gave a very unpleasant-looking fire. With reference to the loss of nitrates from coal, recent experiments on the deposit in London had shown that the soot and dust falling on a given area measured in three or four places in the city was six times as great as in the suburbs. The total deposit was 500 tons per square mile per annum. On the general question of the utilization of oil, gas or solid fuel, we were apt to forget that very much of the prosperity of England depended upon the utilization of its coal supply, and it seemed to him that we should almost eliminate—except as an academic question—the utilization of oil other than the oil derived from our own coal, because otherwise we would be cutting our own throats.

Prof. Burstall, in winding up the discussion, said he had not said anything about the Humphrey pump, because he did not think it could be made in sufficiently large sizes to warrant any application of the sort suggested. With regard to the coke mentioned by Dr, Owens, he did not wish it to be assumed that the method he had indicated would be the same as was at present employed in gasworks. Gasworks at present were terribly handicapped and did not do what they could if they were free from Acts of Parliament which saddled them with penalties not imposed upon any other industry. If the coal were burned in a retort at a temperature of from 800 to 1,000 deg. C. and means taken by which the gas and tar were at once removed, they got a substance which was quite unlike gas coke, because gas coke was usually quenched in water, which was quite wrong. If the coke were placed in a closed vessel and cooled by conduction alone on the Montreal system, a coke would be obtained which would burn perfectly and which gave a very bright and clear fire. The only difficulty with it was that it burned away more quickly than was desirable. It was possible to regulate the products by altering the pressure and temperature inside the retort more than the majority of people were disposed to think, and it really was a question of what happened to be the most valuable product at a particular time. The best results were 14 gallons of tar, from 2 to 2½ gallons of light spirit suitable for motor-car work, and 3 to 4 gallons of fuel oils suitable for Diesel engines, so that a very large proportion of useful substances could be obtained without sacrificing anything.

PLANT OF CANADIAN-VICKERS, LIMITED, MONTREAL.

Principally through the determination of the people of the Dominion of Canada to ultimately possess a navy under their own control, the opportunity of establishing a shipyard in Canada with brilliant prospects for continuous work has arisen. Quick to seize this opportunity Messrs. Vickers, Limited, of England, under the name of the Canadian-Vickers, Limited, are establishing a complete ship-building and ship-repairing plant in Montreal, capable of constructing and repairing the largest vessels using the port of Montreal.

For repair purposes a floating dock was sent out from England capable of lifting 25,000 tons and repairing a ship 700 feet in length.

For ship construction a slip 600 feet in length, but capable of extension, is being constructed on land reclaimed by the Harbor Commissioners at Maisonneuve.

For the walls of this slip and for adjoining machine shops and factories, approximately two thousand concrete piles are being used.

After exhaustive inquiries into the different types of concrete piles on the market, the owners decided that the most reliable was the Pedestal Pile, which had been used with most gratifying results by the governments of the United States and Canada and by the majority of large corporations in both countries. The pile is driven exclusively by the MacArthur Concrete Pile and Foundation Co., of New York, who possess the patent rights for the United States, Canada and other countries.

The general contract was awarded to Mr. E. G. M. Cape, one of Montreal's leading contractors, while the piling was placed in the hands of the MacArthur Concrete Pile and Foundation Co.

Seven hundred and forty-seven of these piles, averaging about 22 feet in length, have been driven under the ship-building slip. Four tests were made with most gratifying results, a load of 45 tons, 50 per cent. more than the load the piles were to bear, showing no appreciable settlement.

The piling required for the shops, etc., is now being driven.

IMPROVED MANAGEMENT OF WATERWORKS.*

Paul Hansen,
Engineer, Illinois State Water Survey.

THE object of this paper is to advocate the employment, on an annual basis, of consulting experts in connection with the operation of small waterworks installations for the purpose of improving the service, the equipment, and the economy of operation. This is by no means a new practice, but it is exceedingly rare, whereas it should be virtually universal.

The means by which the expert's services may be rendered are by occasional visits, say, monthly or quarterly, by the training of the men locally employed, by the periodic examination of records and accounts maintained in accordance with instructions furnished by the expert and finally, by reports with recommendations, submitted at regular intervals. Not more than a few days per month would be occupied by the work involved, and the service may be rendered at what, comparatively speaking, is a nominal fee. For supervising waterworks in a small community $600 should yield a fair compensation. Perhaps a more satisfactory method would be to base the fee upon the gross receipts, making it a suitable percentage thereof.

Need for Expert Supervision.—It is hardly necessary to point out that there is a real need for improved management of waterworks, for the reason that most engineers who have had anything at all to do with waterworks are aware of the very general slipshod methods employed. During the past eight years the writer has had occasion to visit or receive reports upon about two hundred small waterworks in the States of Ohio, Illinois and Kentucky, and not an instance is recalled of a small waterworks installation (that is to say, for a town having a population of about 25,000 or less), where thoroughly effective methods of management were being employed. This does not infer that all these waterworks installations were not giving good service. As a matter of fact, some were giving good service, but generally at unnecessarily large expense, and without adequate records and accounts to show where economies might be instituted. The great majority, however, were giving very inferior service, and showed every outward evidence of carelessness and neglect in management.

Possible Objections to Expert Supervision.—The method of improving the management herein discussed is not advocated for the purpose of increasing the business of consulting engineers, but because it seems the only practicable method whereby the desired results can at present be accomplished. In large waterworks, of course, it is perfectly feasible to engage the entire time of an expert and designate him as general manager. In small waterworks, however, it is not possible to afford the continuous services of an expert. The men ordinarily employed, while they may be intelligent and conscientious, have not had the opportunities of securing the necessary training and experience to render most effective service. But such men, backed by an expert, are as a rule capable of securing highly efficient results. More generally it is found that the waterworks has become a political football and is relegated to the mercies of very incompetent men. In such cases the consulting expert has a very difficult problem, but by tact and by appealing to the more enlightened sentiment of the community he may accomplish a great deal, and because of the very fact that things are in a run-down condition the results of his efforts will be all the more striking.

There may exist the feeling among some, that the supervision of waterworks should be entrusted to local engineers in general civil engineering practice. This would, as a matter of fact, be an injustice to such engineers for the reason that their numerous other duties and employments rarely permit them to acquire the necessary expertness in the restricted field of waterworks. It would appear, therefore, that no conflict of interest exists between the consulting expert and the local engineer. On the contrary, the local engineer should be the first to recognize the necessity of the services of an expert in waterworks operation.

Some persons lean to the belief that supervision over public waterworks should be maintained by some central State authority, and such supervision is certainly desirable, in so far as the sanitary quality of water supplies is concerned. But to enter into the economic phases of waterworks operation to the extent of giving the close supervision herein contemplated, would be altogether impracticable. It would involve the maintenance of an expensive and cumbersome bureau engaged in performing functions which are primarily of local concern, and, moreover, the mere fact that the services of such a bureau would be foisted on the local community would cause the local authorities to be generally antagonistic toward the bureau's requirements. It is not practicable for any central body to go further in this matter than to do just enough to demonstrate the value of expert services in waterworks operation and leave the rest to municipal and private enterprise.

Results Obtainable through Expert Supervision.—Specifically, the results obtainable through expert supervision of a waterworks are:—

1. Better service.
2. Reduction of cost of operation, which, of course, means increased earnings.
3. Anticipation of future requirements.
4. Improved design.
5. A professional and personal advantage to consulting engineers.

Better service means furnishing, throughout the community, an ample quantity of pure and clear water for domestic and industrial purposes, and providing a liberal safeguard against disastrous fires.

Decreased cost of operation means a supervision of all the details of operation in such manner that effective service will be rendered at minimum expense.

Anticipation of future requirements means that all necessary increases in the supply and equipment will be foreseen, so that they may be provided before the community is reminded of its needs by destructive fires, inadequate equipment, or disastrous epidemics due to the pollution of the water.

Improved design will result from a better knowledge of operating conditions than is ordinarily obtainable under present practice by those entrusted with the preparation of plans and specifications. The structural features can generally be readily taken care of, but a common fault is a failure to provide for contingencies encountered in operation. Under the present regime the consulting engineer's connection ceases at about the time that operation begins, and if he has any curiosity to learn if his designs are working out successfully he must satisfy his curiosity at his own expense.

A personal advantage accrues to the consulting engineer from supervision over the operation by giving him continuous and regular employment, thus enabling

* Read before the Western Society of Engineers and published in the Journal for September, 1913.

him to maintain his organization intact. Further, it benefits him professionally by enabling him to concentrate his practice within a limited field, and thus he has the opportunity of increasing his detailed knowledge along his chosen line; in short, he renders himself more expert. There are many men in consulting practice to-day who attempt to cover such a broad field that it may be frankly said they are not thoroughly competent in any one line.

Modus Operandi of Expert Supervision.—For the purpose of illustration and not with any intention of giving a treatise on how to supervise waterworks operations, a brief description will be given of the manner in which expert supervision should work out. Three factors form the basis upon which this work is conducted:—

1. Operation Records, relating to the physical facts connected with waterworks operation.

2. Financial Accounts, relating, of course, to the finances.

3. Technical Skill, which is required in obtaining and interpreting the operation records and financial accounts in such a way that all of the needs of the waterworks plant are fully revealed.

It will be of advantage to inquire a little more fully into these three items and consider them separately.

Operation Records.—Records may be subdivided into several groups as follows: Those relating to source of supply, purification works, pumping station, and line distribution system.

(*a*) *Records Relating to Source of Supply.*—Records relating to the source of supply comprise measurements of the quantity of water available, sources of possible pollution and analyses of the water.

The measurement of the quantity of water available may be made in a variety of ways, some simple, some elaborate, depending upon the character of the source of supply. At any rate, such records are exceedingly valuable in forecasting the adequacy of the source of supply for future requirements. In the southern part of Illinois are two communities, each of which obtain their water supply from an impounding reservoir. During the past summer both of these reservoirs went practically dry, and remained so for some months. In one case no emergency supply could be secured, the community suffered for want of water for ordinary domestic purposes and was left helpless against a conflagration.

In the case of surface-water supplies, the records relating to the condition of the watershed, particularly if the water is used in an unpurified condition, are exceedingly important. Inspections of the watershed, when intelligently made, are much more reliable than analyses in showing dangers to health. It is merely necessary to mention the Plymouth, Pennsylvania, epidemic of typhoid fever in 1885 to demonstrate the futility of analyses in detecting intermittent pollution, such as was responsible for that disastrous outbreak.

Analyses, however, should not be ignored, especially when it is possible to secure a long series of analyses, as they then become a measure of the pollution and give a record of the physical and mineral characteristics of the water. Where purification of the water is employed, such analyses are well-nigh indispensable, as will be discussed later.

It is much easier to give examples of the evil results of failure to maintain proper records regarding the source of supply than to give examples of water famines and other disasters that have been averted by the maintenance of such records. The latter instances are ordinarily not recorded and the danger is never realized by the general public.

(*b*) *Records Relating to Purification Works.*—A volume might be written upon this subject alone. Experiences with small filter plants are most disheartening. Practically all of the small filter plants in Illinois, numbering half a dozen or more, are being ineffectively operated. The same is true in Ohio and Kentucky, and, no doubt, in other States. Some of the difficulty is due to bad design. Very small filter plants are apt to embody bad design, whereas the conditions under which they are operated are such that they should embody the very best design.

Expert supervision over mechanical filter plants (those most generally used in the middle west) does not necessarily result in reduced cost because of the prevalent reprehensible custom of omitting the use of coagulant when the raw water is moderately clear, but within the limits of efficient purification the cost can undoubtedly be reduced. The average small purification works is placed in charge of a pumpman or fireman, having many other duties to attend to, and it is but natural that this, combined with his lack of knowledge of water purification, results in almost total neglect. In many instances such men, through ignorance of the danger of impure water to public health, have no hesitancy in by-passing the raw water into the mains when it becomes convenient to do so.

Records necessary for maintaining proper supervision over mechanical filter plants include analyses of the raw and filtered water, the quantity of water treated, quantity of chemicals used, the frequency of washing the filters, the quantity of wash water used, and numerous other details. For obtaining analytical data there should be established, in connection with every filter plant, however small, a modestly-equipped laboratory. It is an easy matter to train any ordinary waterworks employee of normal intelligence how to make simple analytical determinations which will not only furnish the desired records, but will guide the filter attendant in his daily operation of the plant. If the expert has laboratories at his command, additional analytical control may be maintained on a somewhat more elaborate scale.

(*c*) *Records Relating to Pumping Station.*—A small waterworks pumping station, for which complete records are maintained, is a great rarity. Often it is impossible to get even an approximation of the quantity of water pumped, and generally the only records are from pump revolution counters without any allowance for slippage. It is a comparatively simple matter to weigh the coal and ash, to maintain pumping records both from revolution counters on the pumps and from a meter placed upon the main discharge from the station, and records of the discharge pressure, suction lift, quantity of boiler water used, etc. With such items as these it is possible to always know the condition of the pumps, figure accurately the station duty, and otherwise reveal opportunities for improvement and cutting down the demands on the coal pile. The expert can also arrange, where conditions warrant, for purchasing fuel and possibly other supplies on an analytical basis.

(*d*) *Records Relating to Distribution System.*—Most deplorable of all are the records ordinarily maintained in connection with the distribution system. The location of mains, valves, and service connections is generally stored in the memory of ex-waterworks employees and local plumbers, who regard these facts more or less as stock-in-trade, and would consider it business suicide to record them. In many towns there is no vestige of

a map of the distribution system to be found, and where such maps do exist it is only occasionally that they show mains laid since the original waterworks installation. It is not strange, therefore, that extensions to the distribution system are generally unwisely made, that fire pressure is often lowest where most needed, and that there are many undetected leaks and thefts of water. In the hands of an expert all of these difficulties may be easily overcome simply by the maintenance of complete maps and plans, by periodic inspections, and by occasional tests for pressure, leakage, and waste.

Financial Accounts. — Waterworks accounting, especially in municipally-owned establishments, is usually in a chaotic state. About all that is ordinarily recorded are the gross receipts and gross expenditures, roughly itemized. Capital accounts are almost unheard of, and it is often impossible to get even approximately the cost of the plant. In many municipal plants large donations from public funds are calmly included as earnings. Such items as depreciation, allowances for taxes, interest on investment, sinking fund, rent, etc., are altogether ignored. If the gross receipts, no matter from what source exceed the gross expenditures, no matter for what purpose, a profit is proudly proclaimed. In some instances, on the other hand, large numbers of free service connections make a waterworks appear as a losing proposition, whereas suitable compensation for such services would place the plant upon a sound financial basis.

Correctly-maintained accounts should display fully itemized capital accounts, maintenance accounts, repair accounts, replacement accounts, sinking fund accounts, depreciation accounts, interest accounts, and, in fact, every item that enters into waterworks construction, operation, and maintenance should be carefully recorded in its proper place. In addition, there should be maintained accounts showing unit costs for operation and construction. These latter are very valuable in making comparisons with other plants and with the same plant in other years. Accurately-maintained accounts are particularly serviceable in the adjustment of water rates. The establishment of water rates is, at the present time, on a most unscientific basis, and it is common practice for small communities to adopt, parrot fashion, the rates established in some other community, regardless of the manner in which the water is obtained and the cost of delivering it to consumers.

Technical Skill.—But little can be said with respect to technical skill. It is primarily a matter of natural aptitude and experience, and it is needless to say that no one should presume to enter this field of consulting practice unless his natural aptitude and experience have rendered him fitted therefor. Aside from the maintenance of records and financial accounts it is necessary for the consulting expert to thoroughly instruct the men locally employed in their respective duties, and this necessitates, of course, skill and a thorough knowledge of such duties on the part of the expert. The analytical mind of the expert also enables him to discover opportunities for modifying methods of operation which the more or less untrained man would fail to see.

To summarize: The employment of consulting experts to supervise the operation of public water supplies and other public utilities in the small communities, constitutes a simple and the only practicable method whereby the operation of such utilities may be rendered efficient, whereby the design may be improved, and whereby there will accrue a distinct professional and financial advantage to the experts. Once this system is fairly tried it is hard to believe that it will not gain general favor.

BUCKET ELEVATORS.

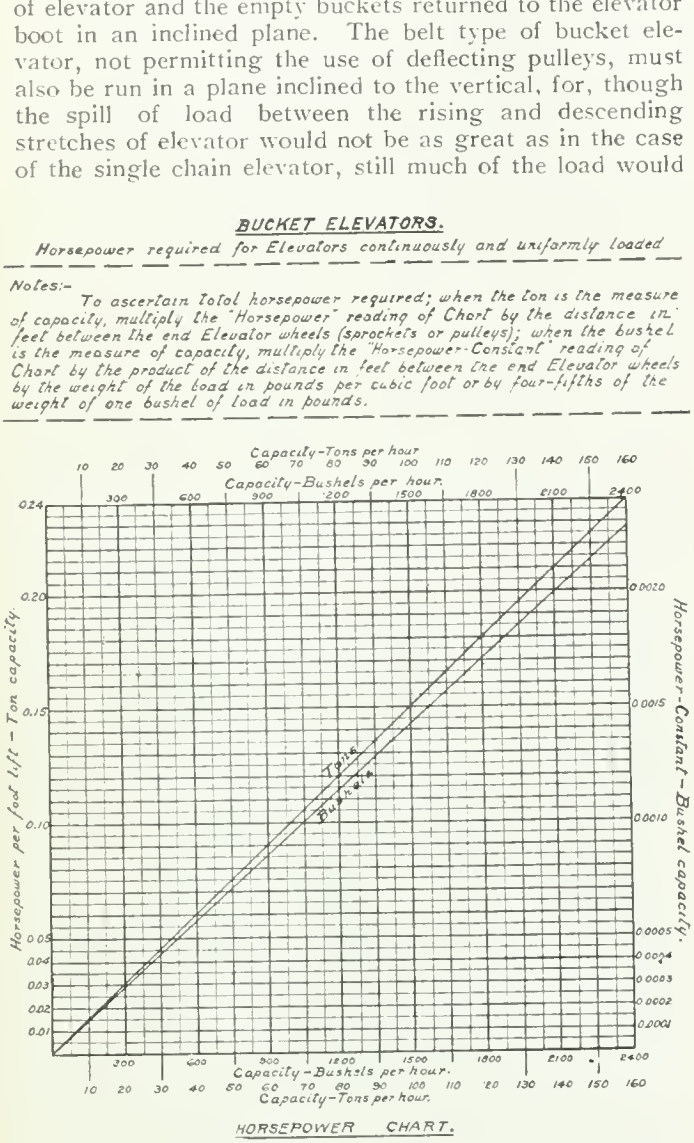
By Reginald Trautschold, M.E.

ALL the material handling equipment so far considered in this series of articles has one and the same drawback—so serious that in some installations use of such apparatus is impossible or inadvisable—and that is its limitations in elevating operations. Flight conveyers, belt conveyers and to some extent even screw conveyers are used to raise material from one elevation to a higher one, but such operation necessitates the load being carried up a comparatively gradual incline so that considerable space for equipment is necessary before any relatively great lift is possible; even when the elevating system consists of a system of several inclined conveyers that deliver their load from one to the other and are arranged as compactly as possible, such as systems of criss-cross conveyers. The logical procedure is to place the load in a bucket and raise it in a vertical or nearly vertical plane—that is, when space is not available for the more cumbersome arrangement of elevating in slightly inclined planes. By substituting a succession of relatively small buckets, attached to an endless chain or belt running over suitable sprockets or pulleys, so that they may be raised continuously, the material may be elevated in small individual loads so that at the higher elevation it is practically delivered in a steady and uniform stream, thus greatly increasing capacity of elevating apparatus and supplying the material in quantities that can be easily and rapidly handled from that point, when further conveyance is necessary, by other conveying machinery, or can be efficiently disposed of by chutes, etc. Such a system for elevating materials comprises what is known as a "bucket elevator."

Two general types of bucket elevators are in common use, those in which the buckets follow one another in close succession (continuous bucket elevators) and those in which the buckets are attached to chains or belts so that there is an appreciable space between succeeding buckets. The continuous type is not now as commonly used as formerly nor as commonly used as the standard type of bucket elevator in which the buckets are spaced further apart and at regular intervals. Continuous bucket elevators, however, possess certain advantages over the more common type of elevator, so cannot be overlooked in a comprehensive discussion. They will be considered then, but after taking up a careful study of the standard bucket elevator.

Bucket elevators in which the buckets do not follow one another in close succession may be of three general classes: 1st, those in which the buckets are attached to a single endless chain; 2nd, those in which the buckets are attached to two matched strands of endless chain; and 3rd, elevators in which the buckets are attached to an endless belt. Bucket elevators in which only a single chain is employed on which to carry the buckets are nearly always installed at an inclination with the vertical in order that the load may be properly discharged from the buckets as they pass around the head elevator sprocket, for a vertical elevator of this kind would spill a large portion of its load between the two runs of buckets, or, if run at such a speed as to assure proper discharge of load as the buckets passed the top of the head elevator sprocket it would be impossible properly to fill the buckets, to say nothing of the difficulty of properly handling the load discharged at the necessarily high speed. Equipment employing two chains for carrying the buckets may be similarly inclined or may be run vertically if choke sprockets are employed to deflect the

return (downward) run of conveyer close to the head elevator sprockets, or if the rising buckets are carried over a short more or less horizontal path before they descend to the elevator boot to be refilled—i.e., causing the path of the buckets to follow the outline of a right-angle triangle, the loaded buckets ascending the vertical stretch, then being carried and unloaded over a horizontal section of elevator and the empty buckets returned to the elevator boot in an inclined plane. The belt type of bucket elevator, not permitting the use of deflecting pulleys, must also be run in a plane inclined to the vertical, for, though the spill of load between the rising and descending stretches of elevator would not be as great as in the case of the single chain elevator, still much of the load would



BUCKET ELEVATORS.
Horsepower required for Elevators continuously and uniformly loaded
Notes:-
To ascertain total horsepower required; when the ton is the measure of capacity, multiply the "Horsepower" reading of Chart by the distance in feet between the end Elevator wheels (sprockets or pulleys); when the bushel is the measure of capacity, multiply the "Horsepower-Constant" reading of Chart by the product of the distance in feet between the end Elevator wheels by the weight of the load in pounds per cubic foot or by four-fifths of the weight of one bushel of load in pounds.
Capacity-Tons per hour
Capacity-Bushels per hour.
Horsepower per foot Lift - Ton capacity.
Horsepower-Constant - Bushel capacity.
Ton line
Bushel line
HORSEPOWER CHART.

fail to reach the discharge chute of the elevator and material would fall against the descending belt and be carried about the boot (lower elevator) pulley, causing disastrous wear to the belt, possible wreckage of elevator, etc.

Standard bucket elevators, of any of the three classes, are nearly invariably similar so far as their drives and loading equipment are concerned. They are driven, through a train of reducing gears ordinarily, by their head sprockets or pulleys and are loaded from an elevator boot which ordinarily contains adjustable take-up bearings for the boot sprocket or pulley by which the tension in the return run of buckets may be regulated—the excess slack taken up. Frequently the elevator is enclosed in a casing, from the elevator boot up, with suitable outlet for the discharge, which serves to protect the equipment from injury and to return any spill of the load to the elevator boot for re-handling. Modifications of these general types of elevators naturally exist, excluding special elevators for handling materials in barrels, boxes, bales, etc., etc., such as elevators in which the lower end consists of a more or less horizontal stretch over which the load is scraped or dragged, as in the case of a flight conveyer, before the buckets start their operation of elevating or where the upper end of the elevator is carried over a similar stretch before entirely discharging its load, but such modifications so closely resemble "bucket carriers" that they will be overlooked at present and referred to again when discussing the more complicated combined bucket elevator and conveyer, the bucket carrier. Limiting this discussion to the ordinary type of standard bucket elevator, therefore, further description is unnecessary owing to the extreme simplicity of the equipment.

Table VIII.—Capacity of Bucket Elevators (Standard Buckets)—Tons Per Hour. Material Weighing 100 Pounds Per Cubic Foot. Elevator Speed, 100 Feet Per Minute.

Size of Buckets	Buckets spaced 12 in.	15 in.	18 in.
5 in. x 4 in.	6.50	5.35	4.25
6 in. x 4 in.	7.75	6.00	5.00
8 in. x 5 in.	19.00	15.00	12.50
9 in. x 5 in.	21.25	17.00	14.00
10 in. x 6 in.	34.50	26.75	23.00
11 in. x 6 in.	37.75	30.00	25.00
12 in. x 6 in.	41.25	33.00	27.25
14 in. x 6 in.	48.00	38.50	32.00
16 in. x 6 in.	55.00	44.00	36.50
18 in. x 6 in.	61.75	49.25	41.00
20 in. x 6 in.	69.00	55.00	46.00
14 in. x 8 in.	78.50	62.75	52.25
16 in. x 8 in.	90.00	72.00	60.00
18 in. x 8 in.	100.00	80.00	66.00
20 in. x 8 in.	112.00	90.00	74.00
24 in. x 8 in.	128.50	104.00	86.00

The capacity of bucket elevators depends, of course, upon the size of the buckets, their number and the speed at which the elevator is run. The size of bucket also depends somewhat on the character of the material to be handled for bulky materials naturally require larger buckets than those which might be entirely suitable for the handling of fine material. However, the average class of materials usually handled in bulk by bucket elevators does not vary so much as to prevent a fair average carrying capacity being fixed for a bucket of specified size. The shape of the bucket also effects the question of its carrying capacity, but here standardization of equipment has devised a shape of bucket that is almost universally employed or when modified for special installations, such as those in which the inclination of the elevator from the vertical is great, has a carrying capacity about the same as the standard bucket, which is fairly constant for any particular size (size expressed as length x width of bucket) so that, for all practical purposes, the length and width of the bucket determines its carrying capacity. The number of buckets, as they are invariably attached to the chain or belt at regular intervals, depends upon the spacing; while the capacity of any elevator buckets and their spacing being the same, depends directly upon the speed at which the elevator is run, i.e., speed of elevator chain or belt. Table VIII. gives the best ordinary capacity, in terms of tons per hour, of standard bucket elevators, equipped with various common sizes of standard elevator buckets at ordinary standard spacings, when the elevator is continuously and uniformly loaded with material weighing 100 pounds per cubic foot and an elevator speed of 100 feet per minute. For elevators handling material of other weight or at other speeds, capacity varies directly with the weight of the material per cubic foot and with the speed at which the buckets are run. Table IX. gives similar data expressed as the number of bushels of material that can be handled by such elevators in an hour. The question of most efficient speed at which

to run a bucket elevator, the condition upon which the capacity of the apparatus directly depends, is one concerning which there is a great diversity of opinion. It is generally admitted, however, that the most efficient speed for a standard bucket elevator is about the same as that for a flight conveyer handling similar material. Such practice is usually pretty correct and Table X., giving the average actual speed at which a number of very successful and efficient bucket elevator installations are run, confirms the rule.

Table IX.—Capacity of Bucket Elevators (Standard Buckets)—Bushels Per Hour. Elevator Speed, 100 Feet Per Minute.

Size of Buckets	Buckets spaced 12 in.	15 in.	18 in.
5 in. x 4 in.	114	91	76
6 in. x 4 in.	137	110	91
8 in. x 5 in.	335	268	223
9 in. x 5 in.	377	301	251
10 in. x 6 in.	610	487	406
11 in. x 6 in.	671	536	448
12 in. x 6 in.	732	586	488
14 in. x 6 in.	854	684	568
16 in x 6 in.	976	781	651
18 in. x 6 in.	1098	879	733
20 in. x 6 in.	1220	976	813
14 in. x 8 in.	1393	1104	929
16 in. x 8 in.	1592	1274	1062
18 in. x 8 in.	1791	1433	1194
20 in. x 8 in.	1990	1592	1327
24 in. x 8 in.	2388	1912	1592

In the consumption of power, bucket elevators are not particularly economical or efficient, for not only does the force of gravity act directly against the lift of the load but several other operations consume considerable power. For instance, there is the loss due to the inefficiency of the driving mechanism, comparatively heavy friction losses considering the fact that the number of bearings is quite small in any elevator, owing, in a chain elevator, to the individual friction in each link joint of chain which resists carrying the chain about the end sprockets, etc., and, in the belt elevator, to the unavoidable slippage between the elevator belt and the elevator pulleys, the resistance of the material in the elevator boot to the passage of the buckets through the boot as they pick up their load, etc., etc. There is also, in an inclined elevator, a certain slight consumption of energy in carrying the load from the vertical loading plane to the vertical discharging plane, but this latter requirement of power is actually so slight, as elevators are ordinarily installed, that it can be disregarded. The exact value of these inefficiencies and operations consuming power that is not instrumental in raising the load is difficult to ascertain, and no fixed law for arriving at the correct proportion to allow for such losses of power can be advanced. Manufacturers of bucket elevator equipment usually allow a margin of 50 per cent. to cover all requirements for power other than the theoretical amount that would be actually required to elevate the given load from the point at which it is received (in the elevator boot) to that at which it is discharged (over the head of the elevator). Numerous tests of various installations in actual operation tend to confirm this practice and though the percentages of power losses in various operations do vary considerably their sum is more constant and does actually amount to close to 50 per cent. In the derivation of Formulæ XVII., XVIII-a and b average losses and inefficiencies have been allowed for and the results obtained from the use of any of these formulæ will be found to agree very closely with the actual requirements of the average well-installed and properly cared for standard bucket elevator. Chart IV. presents the same data as the horsepower formulæ in a

Table X.—Efficient Speeds for Bucket Elevators Handling Various Materials.

Material	Advisable Speed
Coke	100 feet per minute
Broken Stone (coarse); Lump Coal—R/M	125 " "
Ashes, Lime and Cement	150 " "
Ore, Crushed Stone, Sand and Gravel	175 " "
Fine Coal	200 " "

convenient graphical form that enables the ascertaining of the power requirements of any ordinary installation to be made rapidly and with sufficient accuracy for practical purposes.

Horsepower:

H = distance through which load is elevated—height of elevator—in feet.
W = Weight of load elevated in tons per hour (capacity).
B = Bushels of load elevated per hour (capacity).
w′ = Weight of 1 cubic foot of load in pounds.
b′ = Weight of 1 bushel of load in pounds.

$$\frac{W \times 2000 \times H}{60 \times 33000} = \text{horsepower required to elevate load} = \frac{WH}{1000}$$

$$\frac{B \times 1.25\ w' \times H}{60 \times 33000} = \text{" " " " } = \frac{63\ Bw'H}{100{,}000{,}000}$$

$$\frac{B \times b' \times H}{60 \times 33000} = \text{" " " " } = \frac{50\ Bb'H}{100{,}000{,}000}$$

Power loss consumed in running apparatus..... about 17½%
Power loss due to dragging buckets through charged boot 25
Other unavoidable losses 12½

Then,

HORSEPOWER REQUIRED TO OPERATE BUCKET ELEVATOR:—

$$HP = \frac{15\ WH}{10{,}000} \qquad \text{Formula XVII.}$$

$$HP = \frac{95\ Bw'H}{100{,}000{,}000} \qquad \text{Formula XVIII-a.}$$

$$HP = \frac{75\ Bb'H}{100{,}000{,}000} \qquad \text{Formula XVIII b.}$$

Standardization of bucket elevator apparatus facilitates arriving at the cost of the average complete equipment, but the multiplicity of standard types of buckets, chains, etc., varies to a considerable extent the initial cost of even an ordinary installation, necessitating a formula for approximating the cost of equipment a number of constants that differ for the standard component parts of the elevator. However, as this discussion must necessarily be limited to a consideration of general practice and the class of bucket elevator usually found in installations of such character, it is possible to group the apparatus into classes in which exists an approximately constant relationship as to cost. For instance, the chains customarily employed for bucket elevators may be grouped into two classes: one represented by the ordinary detachable link chain, commonly known as the "engineering chain," and the other by the more costly "combination chain," a chain with malleable iron links and steel pins, or by the relatively expensive all-steel link chains, etc. The cost of the chains of both these groups varies closely with their strength or weight, which in turn varies with the load that the elevator is to handle—one group to a greater extent than the other. Practice has also pretty well standardized the spacing of the buckets for any particular size of elevator (size measured by length x width of bucket) so that the load on an elevator can be expressed in terms of size of bucket, height of elevator and weight of the material handled. A similar relationship exists for elevators employing belts instead of chains upon which to carry the buckets. The elevator buckets are usually of steel or of malleable iron, the latter type of bucket being employed when the load to be handled possesses certain chemical properties or is of a temperature that would

be injurious to steel elevator buckets. The weight of the bucket, governed by the thickness of its walls, depends nearly entirely upon the weight of the material to be elevated. These definite relationships, and the fact that the capacity of a standard proportioned elevator varies with the size of the buckets employed, permit the expression of the cost of the necessary elevator buckets at so much per foot of elevator, depending upon their size, the weight of material handled and whether of steel or malleable iron construction. The balance of the necessary equipment, consisting of elevator boot, drive, sprockets or pulleys, shafting, bearings, etc., does not vary so much in cost with the load carried as with the size of the buckets—at least, in the ordinary installation. In fact, grouping must again be resorted to, for the cost of these parts does not vary to any great extent for elevators of about the same size—that is, the cost of these parts for 8″ x 5″ elevator would not differ much from the cost of similar parts for a 10″ x 6″ elevator. The average carrying capacity of these two sizes of elevators, however, would vary by nearly 100 per cent. All these relationships and conditions are taken into consideration in the derivation of Formula XIX. and a certain allowance is also made for the cost of the elevator discharge chute, so that the costs obtained through the use of this equation will be found to be approximately accurate in the majority of simple bucket elevator installations. It must be remembered, however, that no allowance is made for an elevator casing and, if such is required, it should be figured upon as an extra item—an item of convenience or safety that does not necessarily affect the economic value of the installation.

Initial Cost:

C = Cost of complete bucket elevator equipment in dollars
H = Height of elevator in feet—distance load is raised.
wl = Size of elevator (buckets) = width x length in inches.
S = Spacing of buckets in inches.
w′ = Weight of material elevated (load) in pounds per cu. ft.

$$\text{Cost of elevator chains (engineering chain)} = \frac{0.00656\ wlH}{S} \times w'$$

$$\text{(combination chain)} = \frac{0.01312\ wlH}{S} \times w'$$

$$\text{Cost of elevator belts (high grade rubber)} = \frac{0.00437\ wlH}{S} \times w'$$

$$\text{Cost of standard steel elevator buckets} = \frac{0.02592\ wlH}{S} \times w'$$

$$\text{Cost of malleable iron elevator buckets} = \frac{0.04493\ wlH}{S} \times w'$$

Cost of boot, drive, pulleys, etc. (D = constant) = Dwl.

Then :—

$$C = \frac{(A + B)wl \times H \times w'}{S} + Dwl \qquad \text{Formula XIX.}$$

Where :—

A = Constant = 0.00656—standard detachable chain.
= 0.01312—combination chain.
= 0.00437—high grade rubber belt.

B = Constant = 0.02592—standard steel elevator buckets.
= 0.04493—malleable iron elevator buckets.

SINGLE CHAIN ELEVATORS.

D = Constant = 1.56 when wl does not exceed 24 square inches
= 1.09 when wl exceeds 24 square inches

DOUBLE CHAIN AND BELT ELEVATORS.

D = Constant = 2.01 when wl does not exceed 24 square inches
= 1.40 when wl equals from 30 to 66 square inches
= 1.18 when wl equals from 72 to 96 square inches
= 1.11 when wl exceeds 100 square inches

Assuming that an ordinary installation of bucket is properly cared for and that it is subjected only to the service for which it was designed, Formula XIX. may be greatly simplified and a close approximation of the initial cost of equipment expressed in terms of average tonnage capacity and height of elevator. Such a general equation would not be as accurate for purposes of forming an estimate of the cost of an installation, but is quite accurate enough for purposes of arriving at the probable net operating cost, where the fixed burden of interest on investment, taxes and insurance represents but a comparatively small percentage of the initial cost of equipment. Calculations of depreciation, etc., may be made on such a general equation, for, though depreciation is not constant for elevators subject to all kinds of service or even to average service, the error or increase in depreciation for an elevator handling heavy material would be in large part compensated for by the excess fixed burden charge that would arise from the error in the initial cost, as obtained from the use of such general formula, such initial cost being in excess of the real cost. The expense for power, supplies, etc., being nearly directly proportional to the load handled and height of the elevator and, being a considerable expense in "net operating cost," can be pretty accurately figured and has a marked effect upon the accuracy of Formula XX., by the use of which a conservative and fairly reliable opinion can be formed of the probable net operating cost of any ordinary installation of bucket elevator, knowing the actual cost of power.

Net operating cost (N.O.C.):—
H = Height (distance) through which load is elevated in feet.
= Height of elevator.
W = Weight of load elevated in tons per hour (capacity).
Average cost of equipment :—
= 0.000328 WH + 0.003484 W.
Fixed charges :—
Interest - 6% total cost)
Insurance - 1% = 0.000027 WH + 0.000296 W
Taxes - 2%—¾ cost)
Depreciation, renewals, etc. :—
On elevator buckets .... = 0.000090 WH
elevator chain or belt = 0.000012 WH
balance of equipment = 0.000523 W
Depreciation account = 0.000010 WH + 0.000052 W
Total depreciation, etc. = 0.000112 WH + 0.000575 W
Yearly burden :—
= 0.00014 WH + 0.00087 W
Horsepower, attendance, supplies, etc.:—
P_c = Price (cost) of a horsepower per hour.
N = Number of hours (total) elevator is in use per year.
Cost of power = 0.0015 WHNP_c
attendance, etc. = 0.000075 WHN
supplies, etc. = 0.000055 WHN
Burden depending on use of elevator = 0.0015 WHNP_c + 0.00013 WHN
Then :—
Net operating cost (N.O.C.) per ton :—

$$\text{N.O.C.} = \frac{112\ H + 575 + (130\ H + 1500\ HP_c)\ N}{1{,}000{,}000\ N} \qquad \text{Formula XX.}$$

Examples:

1. Conditions :—
Material elevated 50′ 0″ = H
Service ... . 2400 hours per year = N
Cost of power .. $0.02 per horsepower per hour = P_c

$$\text{N.O.C.} = \frac{5600 + 575 + 19200000}{2{,}400{,}000{,}000} = \$0.0080025 \text{ per ton elevated.}$$

2. Conditions :—
The same as in the preceding example except that service is but 1200 hours per year.

$$\text{N.O.C.} = \frac{5600 + 575 + 9600000}{1{,}200{,}000{,}000} = \$0.0080051 \text{ per ton elevated.}$$

Assuming conditions that are common in practice and which may therefore be taken as representative, it will be noted that there is really very little difference in the average net cost of handling material by a bucket elevator whether the installation is in operation a good share of the year or only made use of for half that time. This is due, of course, to the fact that the item of power, etc.,

which is dependent upon the actual hours of service, plays an important part in the question of cost of operation. This is a decided advantage in dredging and excavating operations, etc., in which modifications of the standard type of bucket elevators are very frequently and extensively employed, as such operations are of necessity intermittent and, though not as conducive to economy as if the apparatus was more mechanically efficient, does enable accurate preliminary estimates of cost to be arrived at, etc., etc.

The continuous bucket type of elevator differs from the standard bucket elevator principally in design, consisting of a close succession of V-shaped buckets, having their sides projecting past the back of the bucket so as to form a kind of chute over which—on commencement of the downward travel of the buckets—the succeeding buckets discharge their load as they pass over the head elevator wheel or sprocket, and in the common omission of loading elevator boot. The elevator may be vertical or lie in a plane somewhat inclined to the vertical. In the former arrangement, take-up bearings must be provided for the tail elevator wheel to permit the maintaining of the proper tension in the elevator chain in order that the return (downward) run of buckets may not oscillate and interfere with the rising and loaded buckets. Inclined continuous bucket elevators, on the other hand, are seldom provided with take-up bearings, the tension in the chain of the rising run of buckets provided by the elevator drive, which for all types of bucket elevators is invariably located at the head of the elevator, keeping the loaded side of the elevator taut while the return run of empty buckets is allowed to descend in the path of a parabola—the exact curvature depending upon the slack in the chain. As appreciable time is required to fill each succeeding bucket of a continuous bucket elevator, and thus realize the full capacity of the apparatus, it must necessarily be run at a comparatively slow speed. It is in this exaction for efficiency that the main advantage of this type of elevator construction lies, and for this reason the continuous bucket elevator is not entirely replaced by the higher speed and cheaper elevator of standard bucket elevator construction. The slow speed of the buckets enables them to be filled directly—that is, the elevator load is usually delivered directly to the buckets, not to an intermediate receptacle from which the load is picked up by the moving buckets, as is the practice for the standard bucket elevator. The slow movement also permits the discharge of load in a comparatively slow-moving stream. Thus, breakage of material by the moving buckets at moment of loading the elevator is minimized, as is also the breakage on discharge.

The carrying capacity of each individual V-shaped bucket of the continuous elevator does not vary greatly from that of the individual bucket of the standard type of bucket elevator, so that the table of capacity of standard bucket elevators can be made applicable to the continuous bucket type of elevator by correcting for the speed of the elevator and the spacing of the buckets; which, in the case of the continuous bucket elevator, is approximately equal to the depth of the V-shaped buckets. The power required to operate a bucket elevator of either the standard or continuous bucket type is the same—elevators of the same carrying capacity—as the descending empty buckets compensate for the power required to raise the buckets themselves on the carrying stretch, so that the formula for horsepower required is the same for either type of bucket elevator. The formula for ascertaining the net operating cost of a standard bucket elevator (the measure of true economic value of the system) is also approximately correct for a continuous bucket elevator, for though the latter type is more expensive in first cost, its depreciation charge, etc., is not apt to be as high. The two inaccuracies tend to counteract each other, besides which any error is discounted by the fact that the major expenses, those for power, attendance, supplies, etc., are about the same under similar conditions of service.

Other modifications of bucket elevators are in common use for handling barrels, boxes, heavy bales of goods and for many other special purposes, but a detailed consideration of such is quite impossible in a limited discussion of this nature. However, the horsepower formulæ will be found to be of considerable value in considering the economic advantages of even such special types of apparatus, as but minor alterations in such formulæ need be made to suit any conceivable system. Net operating costs will vary in each special installation, however, and cannot readily be arrived at without careful consideration of all the particular conditions and requirements. Without such data, an opinion of the economic value of any such apparatus must be based largely upon the convenience that such an installation would promise, but it is usually safe to assume that in addition to convenience a considerable monetary saving would ensue from the installation of almost any kind of apparatus for mechanically elevating materials confined in boxes, barrels, or in other ways—a saving usually approaching that which is possible in the handling of materials in bulk.

DESTRUCTION OF GARBAGE BY INCINERATION.

By H. C. Andrews.

ACCORDINGLY as the population of this country increases so must the representatives of communities and officials in charge of public works give this important matter their more careful consideration, more especially in the large cities and thickly populated areas.

The health of the community is reflected in its commercial prosperity; and, unquestionably the sanitary arrangements of a town go very far towards promoting and maintaining the health and energy of its inhabitants. In this age of the application of science to all questions of sanitation, it is universally recognized that cleanliness (by which is meant the entire absence of filth) is not only "next to Godliness," but is absolutely essential for the prevention of such diseases as smallpox, typhoid fever, and consumption. Students of public health are agreed that such diseases have, in the past, been very largely caused by deposits of refuse providing the breeding ground for the multiplication of the most deadly of the known bacilli; and, as a consequence, the method of dealing with the refuse accumulating daily in a town of any size becomes a vital question.

In Canada, with its hot summer, collections of dumped garbage should be an unknown quantity, and it is surprising that the Department of Public Health should have allowed to exist so long as it has the large and offensive garbage tips one frequently sees, and upon which dwellings are subsequently erected, the occupants of which are likely to suffer from the exhalations that must necessarily arise in such cases.

It has been for some years past an acknowledged fact that the worst of our summer pests, commonly called the house fly, and the blue bottle, thrive and multiply in millions on these heaps, which are in various stages of putrefaction and decomposition; also that these flies are responsible for a large proportion of infantile mortality and other sickness during the summer months.

City authorities preach to the householder to "swat the fly," but if they themselves collected the garbage more frequently and totally destroyed it when collected, they would strike right at the root of the evil, do more to abate the fly nuisance, and incidentally improve the health statistics.

The above is a résumé of what has been preached by the medical health officers in Great Britain, Germany and France for some years past, with the result that the authorities of nearly every densely populated area have at the present time an efficient, and what is really more important, an hygienic method of dealing with the garbage.

Incineration has been nearly universally adopted for this purpose, although in a few cases reducing plants have been utilized. The practice of incineration, the first to be used, is gaining in favor, because it fulfils more closely the combined necessities, efficiency and hygiene, than does disintegration.

The latter may or may not be a paying proposition, as is claimed for it, but the fact remains that the public and expert opinion in the older countries are almost unanimous in deciding in favor of destruction by fire, and obtain thereby a clean innocuous clinker residue, rather than risk the adoption of a plant which in abating one nuisance is likely to create another; and this is the case with any scheme which does not destroy immediately and totally all garbage deposited.

Having thus far proved that incineration is at least the most hygienic method of dealing with garbage, the process of incineration can next be examined.

In the early days of incinerators, many difficulties were encountered which earned for them a none too savory reputation, partly because the plants were too small for dealing with the quantity of material to be consumed.

The heat obtained in the furnaces was not sufficient to destroy everything, and at times the fires were nearly put out, this resulted in ashes rather than clinker being raked out when the fires were cleaned, causing quantities of dust to be always flying about. Unconsumed gases escaped up the chimney causing smoke and evil odors.

All these difficulties have now been overcome and the modern incinerator, as a natural consequence of years of experience and use, is positively without nuisance, and can be worked in close proximity to a residential district, without causing offence.

The work of the employee is not unpleasant, and there should be no dust or overpowering odors within the building itself.

Design of Incinerator Plants.—In designing a modern plant it is the universal practice of engineers to consider the following details:—

1. The furnaces should be able to deal efficiently and easily with the maximum supply of garbage; no storage should be allowed for longer than a few hours.

2. There should be stand-by furnaces or cells so that in case of repairs the capacity of the plant is not impaired.

3. The arrangements for feeding the cells should be such that the garbage may be dumped from the carts, and these released at once with as little delay as possible. On this detail will weigh to a great extent running expenses, but a mechanical feeding device may be adopted to overcome this vital point.

4. The construction of the furnaces must be of suitable design, strong and well reinforced to prevent bulging or collapsing of the arches. The heat of the fires must be intense. The continuous grate is now the only accepted form of fire grate; the cells may be arranged in units, with a combustion or carcase chamber and boiler.

5. There are various types of doors for clinkering the fires and also various methods of clinkering, but a truck running on tracks in front of the furnaces, into which the clinker is raked direct from the fires, is used in most cases, as the truck, when full, can be pushed outside and dumped at any convenient spot outside the building.

6. Forced draft can be obtained by electric or steam-driven fans, the air being drawn by pipes from any desired part of the building. By this means no foul air or dust has a chance to collect within the building itself.

7. If power is required boilers can be introduced and the steam generated entirely by the heat obtained from the incinerator furnaces.

8. The flues should be arranged so as to make it absolutely impossible for unconsumed paper and dust to escape up the chimney.

9. The chimney should be of strong construction and lined, and of ample area to allow for possible additions of extra furnaces.

10. The buildings should be built so as not to be an eyesore to the neighborhood, and provision be made for the attendants' wants, i.e., proper washing accommodation, etc.

Generally speaking, there is always a good outlet for the clinker obtained and it is often turned into a revenue-earning item.

From high-temperature furnaces the clinker obtained is hard and perfectly innocuous and may be used for a variety of purposes. For road beds, for concrete, ground for mortar, for concrete paving blocks, for ordinary filling purposes and several other every-day requirements.

The choosing of a site for an incinerator is often the stumbling block over which all sorts of trouble is encountered, but this should not be the case, as providing the contractor for the plant will guarantee no nuisance, and there are several well-known contractors who would take the onus of such guarantee, the modern incinerator should be no more offensive and certainly less unsightly than many factories.

There are cases known of city councils having been compelled by public sentiment to go to the expense of building far away from habitation and in a few years finding their incinerators completely built around by a very fair class of property-holders.

TRUCKS AND ECONOMY.

A Montreal contracting firm recently undertook to test the practical possibilities of trucks with trailers in work in that city, using one or two trailers, these being animal wagons that had been adapted for the service and which were constructed to be discharged quickly. The trains are made up with two trailers, carrying nine tons, 2.5 tons on the truck and 3.25 tons on each wagon, and it was found that the truck could haul the trailers over comparatively rough ground and in soft roads at a satisfactory speed—at least, fast enough to be very economical. The cost of moving excavated material was, with the loads described, reduced from $1.50 to 95 cents, the comparison, of course, being made with horse haulage. So satisfactory was the trial that the company bought seven four and five-ton trucks and will use them with trailers in excavation work whenever possible, and in other haulage wherever practical.

The Canadian Engineer

ESTABLISHED 1893.

ISSUED WEEKLY in the interests of CIVIL, MECHANICAL, STRUCTURAL, ELECTRICAL, RAILROAD, MINING, MUNICIPAL, HYDRAULIC, HIGHWAY AND CONSULTING ENGINEERS, SURVEYORS, WATERWORKS SUPERINTENDENTS AND ENGINEERING-CONTRACTORS.

Present Terms of Subscription, payable in advance.

Postpaid to any address in the Postal Union:

One Year	Six Months	Three Months
$3.00 (12s.)	$1.75 (7s).	$1.00 (4s.)

CHEMISTRY IN ENGINEERING.

The field of the chemist is many times the magnitude it possessed a few years ago, and it is rapidly co-mingling with many of the branches of the engineering profession. With the exception of mathematics, and perhaps of physics, the science of chemistry stands closest, and as the manufacture of the materials used in engineering approaches perfection, the more pronounced is the handiwork of the chemist.

The production of iron, steel, and the alloys, for varied and special purposes, are examples. The constituents of each are selected in proper percentage by the chemist, and the rules-of-thumb are no more. The chemist furnishes the data whereby the engineer varies the chemical content of his materials to obtain the particular physical characteristics desired. The manufacture of cement is another striking example.

Equally important are the relations of the chemist and the engineer in the matter of water supply and the treatment of sewage. It is what the former finds in the nature and extent of impurities that determines the policy of the engineer in the treatment of the water supply. The utilization of nitrogen, of ozone, or of the much-indulged-in hypochlorite of lime or soda, to destroy bacteria; the introduction of copper sulphate (1 part to one million parts of water) to dispose of algae; the use of alum to precipitate suspended organic matter, without appreciable trace in any instance of the remedial substance in the clarified water—these are notable instances of the work of the engineer wherein he is dependent upon the chemist.

In the growing science of road engineering, with its many complexities; the selection and composition of the materials of construction; problems of water purification, and of the disposal of waste—a knowledge of chemistry is essential to the engineer in many phases of his work, and his engineering skill, supplemented by the expert assistance of the professional chemist, leads one to believe that the advancement of industry would be relieved of a considerable amount of its hazard if there was more of an outward acknowledgment of the interdependence of these two applications of science.

ONTARIO'S TEN-MILLION-DOLLAR ROADS.

Ontario is willing to spend ten million dollars during the next few years on road construction. But it wants one hundred cents' value for every dollar expended. The Commission which was appointed by the Government—Messrs. Magrath, Rankin and MacLean—are therefore going to more trouble in gathering information on roads than did any similar commission ever appointed. They are expected to devise a model system for Ontario—avoiding all the errors made by the State Highway Commissioners in the United States, dodging political "pull," keeping the lid tight on the "pork-barrel," and reducing maintenance costs to the lowest limit consistent with reasonable first cost.

The problems that are being considered by the Commission are included in three general classes—men, methods and materials. More specifically, they come under the headings of legislation, administration, finance, expenditure, construction and maintenance.

The most important part of the legislation is to keep the roads out of politics. To this end the Ontario Com-

mission is studying the Highway Acts of twenty-seven States, noting their weak points and their good points. The Highway Commissioner of each of these States is being consulted as to the success or failure attending the road laws enacted by his State, the changes that have been recommended in the laws and the reasons therefor, and above all, the changes that each Commissioner would like to see made to obtain his ideal, but which he perhaps dares not make on account of politics, public sentiment, poverty of the State coffers, or other reasons. The amount of money placed by the Provincial Parliament at the disposal of its road-building organization must also be carefully considered. Were too much money voted at one time, it is feared that it would tax the contracting capacity of the Province too greatly. It is thought desirable to have only thoroughly reliable contractors build the roads, and to let to each contractor only enough work to ensure his being able to handle it with the most careful attention. The letting of too much work in any one season might result in higher prices and inferior work, it is said.

The selection of the administrative and constructive staffs is most important. Mr. Campbell, the Deputy Minister of Railways and Canals (and why not of Highways also?) said at the banquet of the American Road Congress at Detroit, that proper drainage was the most essential item in road building. The Mayor of Detroit replied that "drainage" is not so important as "foundation"—the foundation of good men to administer the enterprise. It is recognized by the Ontario Commission that it will take some time to build up the personnel of the various highway departments. Men with the proper qualifications must be picked or trained. The administrative policy must be carefully decided; whether it would be better to have division engineers each in charge of certain limited territory, or to have strongly centralized control. Under the heading of administration come also the problems of cost-keeping, purchasing departments, etc.

The financing of good roads may prove troublesome in Ontario. The large mileage compared to population makes financing more difficult than in densely populated States. Various methods of raising revenue are being considered—bond issues, automobile fees, corporation taxes, assessments on railways that would benefit by better roads, etc. The substitution of a money tax instead of the work done on the roads by the farmers is being considered. The wisdom of using convict labor will also be decided.

Provision will be made for the systematic inspection of the expenditure of moneys. Uniform accounting systems must be provided and such statistics kept of all payments that accurate data can be placed before Parliament at all times.

The actual construction and maintenance of the roads causes, perhaps, the most travel by the Commissioners. They will visit ten or eleven States and obtain accurate data regarding costs, lifetime, popularity, etc., of the various types of roads. Hundreds of miles of roads will be inspected.

In order to meet and obtain the good-will of the numerous State Highway Commissioners to whom they will later apply for information and assistance, the Ontario Commissioners gave a luncheon at the American Road Congress and invited all of the State Commissioners. The ice was thus broken, and the interest of each commissioner awakened in Ontario's problems. These State Commissioners are now furnishing the Ontario officials with data concerning dimensions, first cost, wear, maintenance charges, what types are being abolished as unsatisfactory, what types are being substituted as more satisfactory, etc. The relative merits of concrete, brick, bituminous macadam, asphalt block and chemically bound macadams are being investigated; the methods of construction and suitability of gravel, sand-clay and earth roads are being studied.

The Commission is being aided in this work by J. E. Pennybacker, whom they have appointed as a consulting expert, as previously mentioned in these columns.

CANADIAN PUBLIC HEALTH ASSOCIATION. CONVENTION AT REGINA, SEPTEMBER 18, 19 AND 20.

[This article, dealing with that part of the proceedings of the Canadian Public Health Congress at Regina that is of interest to *The Canadian Engineer* readers, was unavoidably precluded from our issue of October 9th; hence its appearance at this late date.—Ed.]

THE Third Annual Congress of the Canadian Public Health Association was held in Regina, Sask., Sept. 18th, 19th and 20th. Upwards of two hundred delegates registered. As indicated in the programme appearing in a previous issue, the work of the convention was divided into eight sections, additional to the general sessions. To each of them the papers presented were of such a nature as to open up a volume of keen and vivid discussion upon all phases of the work which the association has set itself about to do.

The congress had its various sessions well interspersed with social functions of one kind and another, and the city of Regina displayed such an excellent type of hospitality to the visitors as earned for it a highly commendable resolution on the minutes of the association.

There were several papers read at the general session that would have interested a large number of the engineers of Canada, apart from Section VI., which was devoted entirely to engineering subjects, and Section V., which was closely related covering the various phases of sanitary inspection and promotion.

Of the ten papers presented at the Engineers' Section, two, viz., "Mechanical Gravity Filtration at Saskatoon," by George T. Clark, city engineer, Saskatoon; and "The Chemical and Biological Effects of Water Filtration," by H. W. Cowan, chief engineer, Bell Filtration Company, Toronto, appeared in October 2nd issue, and other important papers will be published in due course in these columns.

Among the papers read at the general sessions the presidential address by Dr. J. W. S. McCullough, Provincial Health Officer for Ontario, related a few of the experiences of the speaker in his recent visit to Europe. His address was, in part, as follows:—

"In the province of Ontario, from the fact that the rivers and lakes must become the great sources of water supply, it has become apparent that to preserve these supplies in a pure state, it is necessary to take prompt action to prevent their pollution with sewage. With this end in view the legislature of last year and this year gave very extensive powers to the Provincial Board of Health in this regard, requiring that all plants for waterworks and sewage disposal must have the approval of the Board before any money can be raised for these purposes. In

addition, a further enactment gives the Board power to compel the construction of such works, when, in the Board's opinion, they are required by an urban municipality; and such approval being made, no vote for the electors is required to raise money on debentures for this purpose."

During the present season the Board has been engaged in making a careful examination of the rivers and lakes separating Ontario from the United States, beginning at Fort Francis and ending at the eastern boundary of the province, with a view of discovering the causes and extent of what sewage pollution may exist. Following this, the speaker was instructed by the Government of the province to take up the study of sewage questions in Great Britain and other parts of Europe.

"Of the many extensive works for the disposal of sewage in Great Britain, perhaps the most important are those of Birmingham, Manchester and Glasgow. Many large cities such as Liverpool and Edinburgh have an easy problem—that of letting the sewage go out to sea with a rapid ocean tide. Others, like London, Belfast and Glasgow, send the sludge or solids out to deep sea by vessels, but the hundreds of inland towns and cities must otherwise dispose of it. Since the great water supplies of Great Britain are taken from upland watersheds, it is not, generally speaking, so necessary to have as good an effluent as conditions in most of Canada require.

"The problem of dealing with sewage embraces the disposal of sludge or solids, of the liquid portion of the sewage, and of storm water. Each of these is a problem of importance and difficulty. It is apparent that the sludge problem is the most difficult one, while that of the liquid portion from a sanitary point of view is perhaps the most important."

The major portion of Dr. McCullough's address comprised a description in detail of typical British and German disposal plants with an outline of the methods employed.

Dr. M. M. Seymour, Commissioner of Public Health for Saskatchewan, in his paper dealing with the work which was being done in that province, detailed the methods employed by the Government toward the prevention of disease and the prevention of the pollution of rivers and streams.

Dr. R. E. Wodehouse, a district Health Officer in Ontario, in his paper concerning the field work of an officer in his position, referred to Dr. McCullough's division of the province into seven districts, eventually to be increased to ten, for the administration of public health work.

The first duties of the office pertained to making a careful sanitary survey of each organized municipality in the several districts. These surveys called for a report of the activity of the Board of Health and its officers, the keeping of the vital statistics, the condition of public buildings, the source, nature and management of water supplies, private and public; the sewerage undertakings, both to have maps in detail, in duplicate, one to be retained by the district office and the other to be sent with the report to Toronto office. The schools, ice supply, garbage collection and treatment, hotels, restaurants, railway stations, lanes, nuisance grounds, stagnant water and all things pertaining to public health to be investigated. The epidemiological history of the community, both as to man and animal, were to be reported upon.

The results of the work have been fairly satisfactory. Actual improvements in the state of the provinces' status of health will probably be more grossly evident at the end of three years. Speaking of District No. 7, the one to which the writer is attached, during the past six months five municipal water chlorination plants have been installed upon order, three municipalities have regulated, changed location of or abandoned nuisance grounds. Railways have cleansed the lights of boarding camps and cars, have established sewage treatment plants at their terminal or divisional points, and are reporting surveys of the water supplies used for their dining cars, day coaches and the engines, as this is used by the rolling stock men.

"Standards With Reference to Sewage Treatment" was the subject taken by Mr. T. Aird Murray, consulting engineer, Toronto. The paper dealt exhaustively with the different systems of the treatment of sewage before allowing it to flow into the streams and lakes from which the water supply of towns and cities is taken.

Mr. Murray summarized his paper by stating that in his opinion, based on much observation, there was no standard of treatment which could be generally applied to sewage, but that some system which would do away with internal germs in the sewage should be generally adopted. Such care to some extent must be treated separately according to the local requirements.

The dilution method of treatment as advocated by many engineers because it is the most economical method from a financial point of view was pointed out as a makeshift, which did not protect future water supplies. The different systms of dilution and purification by chlorinization were fully discussed.

With the sewage treatment subject, one of the most important points touched upon by the author was that of the pollution of water supplied. Water supplies, he stated, should be doubly protected by the disinfection of sewage flowing into them and the filtration and disinfection of the water drawn from them which is about to be used. He called attention to the fact that there are many uncontrollable sources of pollution with which it is hard to deal, but ventured the opinion that legislation would be able to control much of the apparently uncontrollable sources of pollution. He pleaded for legislation in Canada before the waterways become hopelessly polluted as they are in the United States and in England.

Section V. brought out several papers of particular value to those who have to do largely with the maintenance of proper sanitary conditions in congested or outlying sections of cities. Mr. E. W. J. Hague, Assistant Chief Sanitary Inspector, Winnipeg, furnished a lengthy paper on the housing problem, recommending a number of remedies to counteract over-crowding, inadequate building laws, etc. Mr. F. Cartlidge presented a paper entitled "City Waste Disposal by Incineration. He briefly reviewed the history of city waste disposal, from the old method of the nuisance grounds, with its unsightliness and the comparatively large area of land laid waste for this purpose, through the different stages in the development of a satisfactory incineration plant down to the present, where it was possible by incineration, to convert the putrescent matter in city refuse into harmless products, by means of combustion.

"The process of incineration," he said, "has made much headway with the introduction of high temperature furnaces of 2,000 Fahr. and upwards by means of forced draught, induced either by powerful fans or steam blast. The heat obtained in these furnaces is sufficient to consume anything put into them.

"In the older types of independent cells the introduction of a fresh charge of refuse resulted in the lowering of the temperature with imperfect combustion of the gases, a condition which is obviated by increasing the number of cells, and by charging them in turn so that some are at their greatest heat while others are being charged.

"With present improved methods of construction such high temperatures are often obtained that no inconsiderate amount of waste heat is available, and steam boilers are generally made a part of the equipment. This will provide steam for the blast or to drive the fan, and by absorbing heat from the waste gases will reduce the cost of repairs to flues and a less expensive and lighter firebrick in the chimney will suffice.

"Naturally, in these notes a description of the incinerator at Moose Jaw, and the methods for operating same may be much in evidence, as it is operated under similar conditions and with the same class of refuse that will be met with elsewhere throughout Western Canada.

"In the collection of our refuse all house and trade refuse are collected and dumped together at the incinerator, where it becomes automatically mixed with a larger quantity of stable manure, as both are being delivered in the course of the day.

"To obtain the best results and complete combustion, the conditions necessary are:—

"A sufficient air supply brought into intimate contact with all parts of the fuel and the maintenance of the temperature up to ignition point until the whole is consumed.

"All modern high temperature incinerators will have the following features: Forced draught, either steam blast or air; a drying hearth above the grate; a combustion chamber where the gases are mixed and raised to incandescence; a steam boiler for utilization of waste heat; an economizer to heat the feed water, and a regenerator for the air blast. Other things of equal importance are some arrangement to discharge direct into the combustion chamber from above, carcases of horses, mattresses, wet damaged fruit and certain other things that cannot be consumed during the burning of a single fire on the grates, and which would come out with the ashes only partly burned and require to be thrown in again. A storage floor to hold 24 hours' accumulation of refuse, and tipping platform of such size and arrangement that the ordinary box wagon can safely be brought to the tipping sill.

"The incinerator at Moose Jaw is a Heenan and Froude high temperature, with three cells in one continuous chamber. Fires are fed from the top, where the refuse is shovelled into hoppers, the top of which are with the floors of the tipping and storage platform. The blast is air, supplied by fan and drawn from above storage floor. A pressure of from 3 to 4 inches is given, with temperature around 2,000 Fahr. The fan for the blast is driven by an enclosed steam engine which, with the feed pump, absorbs approximately 15 per cent. of the power generated by the waste heat.

"Under ordinary working conditions an average of two tons of refuse per hour is consumed, and the fires are cleaned about every two hours. The operating costs average a little over $1.00 per ton.

"Until quite recently no serious effort was made to utilize the power in the steam generated by waste heat. Observations have been made several times under ordinary working conditions which indicated that after allowing for use on the plant itself there was at least 100 h.p. available for other purposes. This is now to be used for the purpose of pumping sewage at the disposal works, which are situated conveniently near, the steam being piped across the short distance in 4-inch insulated pipes.

"Without going outside the scope of the Health Department there are many uses to which this waste steam might be put and so reduce the cost of disposal of refuse, for instance: The establishment of baths and washrooms; steam disinfecting station; electric lighting of depot and works; or even to generate current for ordinary purposes.

"Of other residuals very little has been made so far. The clinker is made small in size, and when free from dust is a suitable material for bacteria beds, some having already been used for that purpose. The dust from the combustion chamber can be used as a body for disinfecting powder and in a small way this has been experimented with."

Business Session.—The Association elected the following members to form the executive committee for the ensuing year: President, Dr. M. M. Seymour; general secretary, Major Lorne Drum; treasurer, Dr. George D. Porter, and Dr. C. J. Hastings, M.H.O., of Toronto, Dr. C. A. Hodgetts, of Ottawa, and Dr. Duncan Anderson, of Toronto. Dr. Adam H. Wright, chairman of the Provincial Board of Health of Ontario, was elected honorary president of the association for the ensuing year.

The next annual congress will be held at Fort William and Dr. Woodhouse, the district sanitary officer of that city, has been appointed the convener of the local arrangements committee.

Among the resolutions adopted was one authorizing the appointment of a committee to assist in the formation and operation of a proposed Federal Health Department. Another read: "That in the opinion of this association it is a matter of great importance that the Dominion Government do take steps to create a Department of Public Health in order that all federal branches dealing with health work may be co-ordinated under one administration."

Another fixed the membership fee of the association at $3.00 per annum.

Mr. J. T. Vallance, of Lethbridge, Alberta, read a very interesting paper on "Public Abattoirs," going fully into the questions of cost, methods of operation, sanitation and other details, expressing himself of the firm belief that civic abattoirs will prove themselves not only self-supporting, but profitable. He spoke of the manner in which the institution of civic abattoirs in England and Germany had reduced materially the cost of living.

"Leaves From An Inspector's Note Book" was the subject of a paper by Mr. H. D. Mathias, of the Health Department of Regina. The paper dealt largely with the training of a man for sanitary inspection, and with the essential recognition of the provision of a pure and ample supply of air and water as an assurance of safety and health.

Mr. Thomas Watson, of Regina, dwelt upon the legal aspect of the sanitary inspectors' work. In the course of his discourse, Mr. Watson mentioned the unanimity of the various health acts of the Dominion in placing under the control and jurisdiction of the Boards of Health all that properly belongs to sanitary and health matters; but added that in spite of this there is a tendency among municipal authorities to deprive sanitary inspectors of a good deal of authority they should possess with respect to certain elementary fundamentals under their supervision.

OTTAWA WATER SUPPLY PROJECT.

FOR years the supply of water for domestic use in Ottawa has been unsuitable. The summer of 1912 was marked by the visitation of a serious outbreak of typhoid, which brought the problem into prominence, and called for a rapid and permanent solution. The result has been that in the past year the civic authorities have kept the matter constantly under probe, until the present time finds them furnished with numerous reports covering all feasible sources of supply.

There are five possible sources, viz., Ottawa River, Madawaska River, Lake Deschenes, McGregor Lake, and Pemichangaw Lake.

The Ottawa River, the present source, has been reported upon as being unfit for use without mechanical filtration and chemical treatment. In February, 1913, Sir Alex. Binnie and Dr. A. C. Houston advised the city to abandon the Ottawa River as a source of supply. Then, in April the Ontario Provincial Board of Health advised the city that the use of the Ottawa River without mechanical filtration would not be permitted. The decision was backed by the fact that Ottawa had had 3,000 cases of typhoid within 18 months from using this water. The filtration scheme has not met with favor at the hands of the ratepayers, generally, when advanced for their consideration. The proposal submitted last year did not provide for future growth, sentiment was against chemical treatment, and the risk of contamination from the unsanitary waters of Nepean Bay, under which the supply had to be conveyed, was important and against the adoption of the scheme.

Lake Deschenes.—On October 3rd, 1913, City Engineer Currie submitted a report in answer to the following Council inquiry:—

"If the city of Ottawa continues to use the Ottawa River water in its natural condition as a permanent source of supply, what would be the best point from which the water should be taken, and what works would be required to be constructed, with an estimate of the expense of such works?"

His report stated that in his opinion the most suitable point from which to take the water was a little west of Ennis Point, in Lake Deschenes, and opposite Aylmer Island. This is over 14 miles from the pumping station. Mr. Currie found that the gradients were such that the water could not be carried by gravity to the pumping plant, and that, therefore, another pumping plant would need to be installed and operated at Lake Deschenes. As no hydraulic power could be secured there, this plant would require to be operated by electric power.

The city engineer proposed that a small low-level service reservoir to hold ten million gallons be constructed just inside the city limits to provide a reservoir of water in case of fire, and to enable the water to flow by gravity from the reservoir to the present pumping station. He also proposed to have two 48-inch pipes from the intake at Lake Deschenes to the service reservoir, and two 42-inch pipes from the reservoir to the pumping station. The estimated cost of this project was estimated at $2,900,000.

A later issue will contain a more detailed report of Mr. Currie's investigation.

McGregor Lake Supply.—This includes a large number of lakes at distances varying from 15 to 30 miles to the north of Ottawa. The engineering features connected with this source of supply for the city will appear in a later issue. It is generally conceded that filtration would be necesary. An estimate of the cost of the necessary works is placed at $7,054,000.

Madawaska River.—Owing to the necessary length of pipe-line from this source to the city, the variations of level along it, and the low total elevation above Ottawa, this project has not met with favor. It is also objected to because of its questionable quality, and the uncertainty of continued safety of river water generally, which feature applies forcibly to the proposition.

With this brief summary of the situation, attention is directed to a report, submitted last week. It has already been mentioned that in February Sir Alex. Binnie and Dr. A. C. Houston visited Ottawa, studied its water supply, advised the abandonment of the Ottawa River as the source, and recommended an uncontaminated source, such as is afforded by the lakes lying between the Gatineau and Lievre Rivers. The city was also advised to undertake a careful survey of the district. Consequently, arrangements were made with the Dominion Government, whereby contour maps and other necessary information have been obtained.

On May 5th, the City Council requested Sir Alex. Binnie to make a detailed report, and the result has been a thorough investigation by his staff of all the sources of water supply, including a detailed examination of the proposed routes for the aqueducts, service reservoir, etc.

In the report the city is recommended to use every effort to bring down the rate of water consumption, which at the present time averages 170 gallons per capita per day. Contrasting this consumption with that of other Canadian cities, according to the report of the Commission of Conservation, 1912, the report deems it feasible to reduce the water supply per capita to 100 gallons per day. It is on this assumption that the capability of the various sources of supply to provide for 250,000 persons with a possible future population of 750,000, has been considered.

The report divides itself into a consideration of two schemes: (1) Supply from Thirty-One Mile and Pemichangaw Lakes. (2) Supply from McGregor series of lakes. These sources are shown in Fig. 1. The following is extracted from the portion of the report dealing with the former:—

Thirty-One Mile and Pemichangaw Lake Scheme.—These two lakes are situated on the east bank of the Gatineau River at a distance of about 40 miles to the northward, measured in a straight line from Parliament Hill to the south end of Pemichangaw. The surrounding area of land which drains to these lakes is dotted with numerous other smaller lakes, but the above are the only lakes of any importance and extent.

As to the quantity of water that may be obtained from this source, the three important factors upon which the service from any drainage area depends, respond to investigation in the following way:—

(1) The extent of the drainage area is approximately 150 sq. miles.

(2) The quantity of rain or snow annually precipitated on this area averages 37 inches.

(3) The run-off is conservatively placed at 13.6 inches.

Taking 13.6 inches of run-off from a catchment area of 150 sq. miles, the average yield approximates 81,000,000 gallons per day, ample to meet the requirements of a population of 750,000.

The drainage area has been found free from peat or other surface deposits liable to discolor the supply. The water is bright and clear and of exceptionable purity, and if steps are taken by the city to prevent future contamination, the report forecasts not the slightest neces-

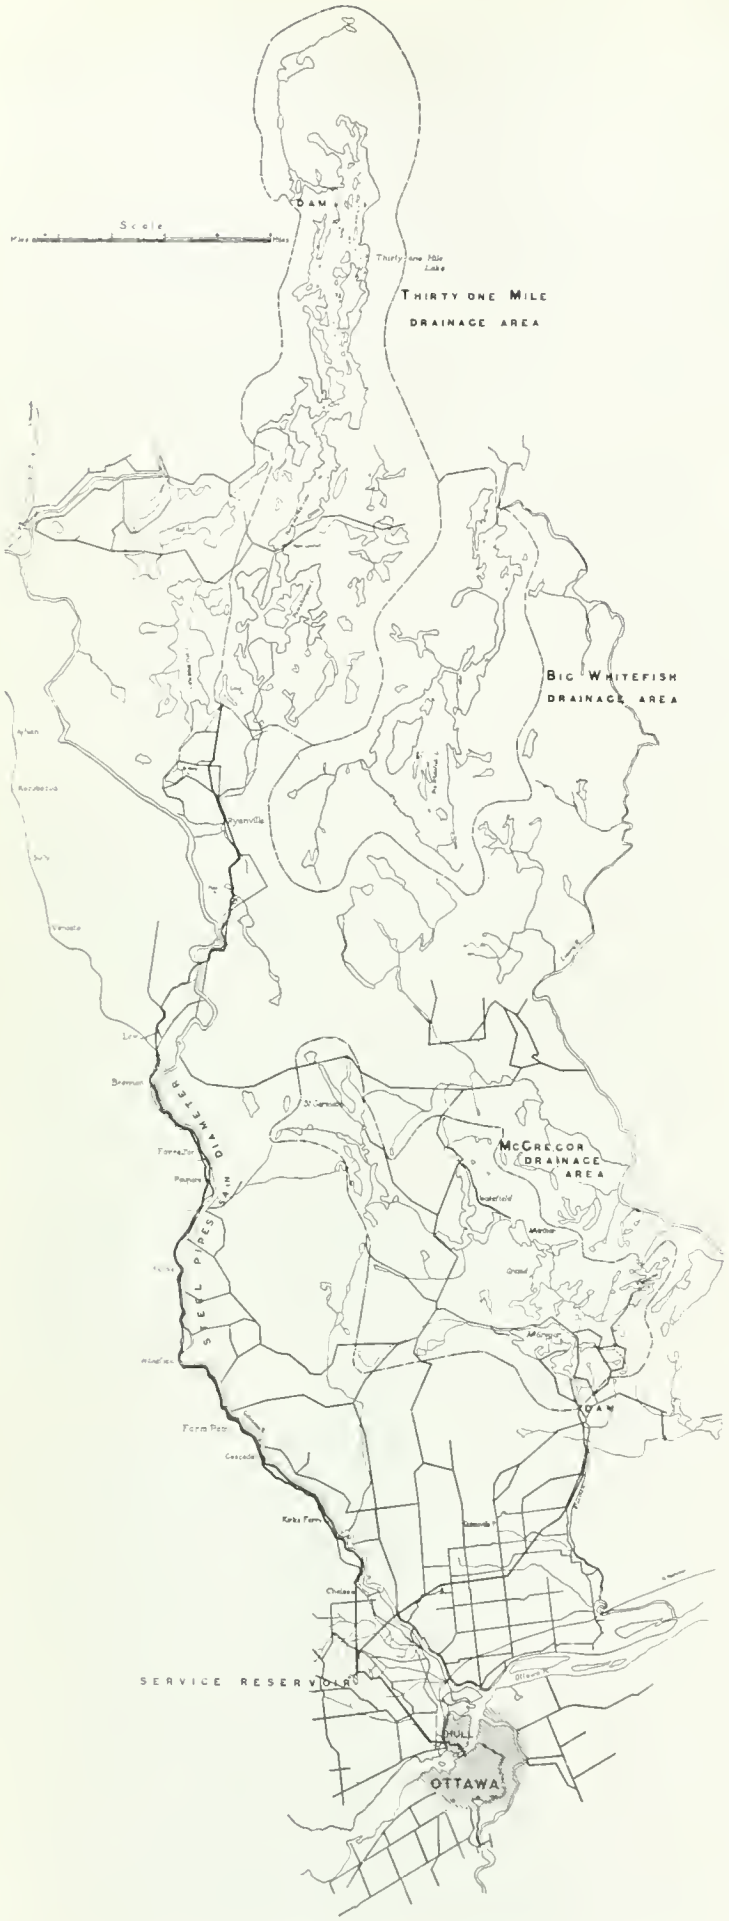

Fig. 1.—General Plan of Storage Area.

sity for filtering this water at any time. It pronounces this source as one of the finest supplies in the world.

The method of collecting and storing the water is as follows, according to the report Fig. 2 illustrates the plan herewith described:—

There are four lakes which form a chain stretching approximately north and south. Commencing at the north is Mitchell Lake, a small lake which discharges through a narrow gorge at its outlet into a channel which finds its way into the Gatineau. This lake has a surface area of 0.7 square miles, and the water level in Sept. was 523 feet above datum. It receives the entire discharge of Thirty-One Mile and Pemichangaw, and a narrow rocky gorge, already referred to, forms an admirable site for a dam.

The next in the chain towards Ottawa is Thirty-One Mile Lake, which is about 18 miles in length, with a water area of 18 square miles, the water level this summer being about 530 feet above datum. Immediately to the south, and separated by a narrow neck of land, lies Pemichangaw, with a water area of 6 square miles and a length of about 5 miles, the water level this summer being about 552 feet above datum. Crossing the height of land to the south-west of Pemichangaw we come to Long Lake, having a length of about 1¼ miles, and a water area of about one-quarter of a square mile. The distance between Pemichangaw and Long Lake is about 3,000 feet, and the water surface of Long Lake is 561 feet above datum.

It is proposed to tunnel through the ridge between Pemichangaw and Long Lake, and by means of the dam at the outlet of Mitchell Lake to bring all the lakes to one level, namely, 570 feet above datum, and to start the aqueduct to Ottawa from the south end of Long Lake. This would mean raising Mitchell Lake 47 feet, Thirty-One Mile Lake 40 feet, and Pemichangaw Lake 18 feet.

The contour surveys to determine the top water area at this level are not yet completed, but the total when brought to this uniform level of 570 feet above datum will increase to about 35 square miles in area. One foot difference in level of a water surface having an area of 35 square miles represents about six thousand one hundred million gallons, and 18 inches would give a year's storage of a daily flow of 25,000,000 gallon, 3 feet would give sufficient storage for 50,000,000 gallons per diem, and 4 feet 6 inches sufficient for 75,000,000 gallons per diem. The maximum variation in water level would, therefore, be small.

The dam at Mitchell's Lake would be designed so as to overflow at a height of 570 feet, the total content of masonry to this level being estimated at about 9,100 cubic yards.

It has already been stated that the dam would be constructed so as to raise the level of the lake to 570 feet above datum, which means that Thirty-One Mile Lake would have to rise 40 feet, and Pemichangaw 18 feet. Owing to the enormous area of Thirty-One Mile Lake it would take five or six years before this lake would rise even to the level of Pemichangaw, that is 22 feet, and ten or twelve years before it reached the final level of 570 above datum. It is obvious that the scheme should be so laid out as to enable water to be brought forward to Ottawa as soon as the aqueduct and service reservoir can be completed, which can be effected in the following manner:—

Pemichangaw and Long Lake have a total drainage area of about 41½ square miles, and would yield on the basis of a runoff of 13.6 inches about 22½ million

gallons per diem, or sufficient for the needs of the city for many years. The level of Pemichangaw Lake varies between about 554 and 552 feet above datum, and the lake is separated by a narrow neck of land known as Point Comfort from Thirty-One Mile Lake, which is about 30 feet lower in level. This neck of land acts as a natural barrier, which retains water at the higher level in Pemichangaw, and is traversed by a narrow gorge, through which the water is discharged into Thirty-One Mile Lake. This gorge is blocked by a wooden dam provided with sluices, and the fall of water from one lake to the other is utilized for a saw-mill. Water also finds its way into Thirty-One Mile Lake from Pemichangaw through debris overlying the rock, filling the bottom of what no doubt was at one time a valley of discharge from one lake to the other. There are underground fissures connecting the two lakes, and the measurements which have been taken this summer show that when the water level in Pemichangaw stood at 554 feet above datum the amount of water which got through this debris or surface fissures in the rock amounted to approximately 8,000,000 gallons per diem; but when the water level in the lake had fallen to 552 feet above datum the discharge was very small, indeed, showing that the water was really finding its way from one lake to the other namely, 81,000,000 gallons per diem, being passed through into Long Lake without appreciable loss of head.

The best location for the invert of the tunnel would be about 6 feet below the present level of Pemichangaw, or at about 540 feet above datum, 24 feet below top water level when brought up to 570 feet above datum.

This tunnel would terminate at each end in covered shafts, the water entering and leaving the shaft well below the water level of the respective lakes, to remove all danger of freezing.

Works at Long Lake.—Long Lake varies in depth from about 20 feet to 50 feet, being shallow towards the north end and deep towards the south. This lake, like Pemichangaw, is formed by a natural barrier, and the water issuing from it passes over this barrier by means of a series of small falls and cascades to the valley below, dropping 50 or 60 feet in a short distance. A short cutting through this barrier will, therefore, enable the water to be drawn down 20 or 30 feet without any difficulty.

The shores of the lake are steep and rocky, but at times during and after windy weather the sediment in the bottom is stirred up by wave action. This action does not extend to any great depth, probably not much

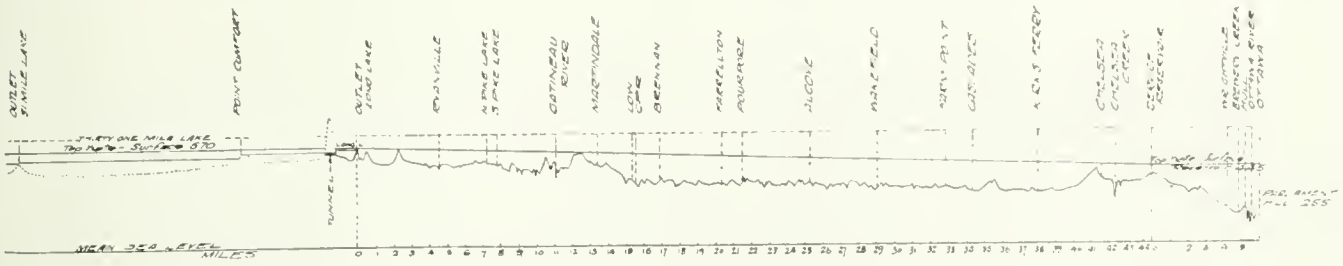

Fig. 2.—Profile of Lakes and Pipe Line.

through a comparatively shallow channel. It is proposed to open a trench first of all across the old channel, and fill with concrete so as to cut off the supply that would leak away when the water level is raised to 554. This would enable the water to be retained in Pemichangaw Lake, upon which the city could draw as soon as the aqueduct is completed. The present water area of Pemichangaw is about 6 square miles, and 5 feet in depth on that area would represent the total storage required for the first instalment of 25,000,000 gallons per diem. Assuming that the minimum draw-off level was to be 549 feet above datum, or 3 feet below the present level, the maximum level at which the water would overflow would be 554 feet above datum.

The dam at the outlet of Mitchell's Lake should be proceeded with as soon as the necessary arrangements could be made, so that Thirty-One Mile Lake can be gradually raised to such a level as to flow towards Ottawa by means of the aqueduct. The report includes in the estimate for the supply of 25,000,000 gallons the cost of the dam at Mitchell's Lake, and also the necessary clearing to bring Thirty-One Mile Lake and Pemichangaw Lake to the level of 570 feet above datum, when storage will be provided for the full yield of the drainage area, or 81,000,000 gallons a day.

Tunnel between Pemichangaw and Long Lakes.—To bring the water of Pemichangaw into Long Lake, from which lake the aqueduct would start, will necessitate constructing a tunnel through the height of land between the two lakes, a distance of about 3,000 feet. This tunnel should be made about 7 feet internal diameter so as to permit of the whole available yield, below 10 feet. It is, therefore, proposed to remove the sediment, logs, etc., when the lake is drawn down so as to prevent similar action taking place in the future.

The outlet works would consist of a straining tower about 50 feet high, covered at the top, and provided with copper gauze screens; the water entering the tower at a depth of 7 or 8 feet below the minimum water level of the lake and after passing through the screens leaving by means of a culvert through the natural barrier already referred to, to the commencement of the pipe. It is proposed to install a small water-driven turbine so as to work a pump for supplying high-pressure water for washing the screens. The power for this turbine would be supplied by allowing water to pass from the lake to the valley below, the turbine being situated at the foot of the fall, which has already been referred to. The screens would be made so that they can be lifted in rotation for cleaning purposes without interfering with the flow of water, and the dirty water, after cleaning, would be discharged into the valley below the straining tower.

Description of Pipe Line.—The top water level of the service reservoir would be 445 feet above datum. The distance between the outlet and the service reservoir is about 235,000 feet, and allowing for losses of head at the reservoir, the hydraulic gradient would be approximately 1 in 1960, and with this gradient a welded or lock-bar steel pipe, 54 inches in diameter, would deliver 25,000,000 gallons a day, allowing for future encrustation. If rivetted steel pipes were used the internal friction is slightly greater on account of the rivet heads and the diameter of the pipe would be slightly larger to discharge the same quantity of water. The

estimate has been based on approximate quotations received for 54-inch welded steel pipe, 7-16ths of an inch in thickness. With soft water considerable encrustation may be anticipated, but seeing that the Thirty-One Mile Lake water contains about four and a half grains of lime per gallon it is probable that this may not take place to any appreciable extent. The Ottawa River water contains about two and a half grains per gallon, and appears to have had very little effect on steel pipes which were laid many years ago without any protection by means of coating. It has been found that steel pipes are also liable to corrode from the outside if laid in saline or marshy ground unless special precautions are taken. The best protection in such cases is to surround the pipe with tarried hessian or jute, and provision has been made in the estimate for this precaution where the pipes would be located in swampy ground. To prevent freezing in winter the pipes should be laid so that the bottom would come a minimum of 8 or 9 feet below the surface of the ground, and the estimate has been got out on this assumption.

After leaving Long Lake the pipe would pass southward gently undulating cultivated land for a distance of about one mile until a cedar swamp is reached, which would have to be traversed for a distance of another mile, when open, cultivated land is again reached about two miles north of Ryanville. The ground is of much the same character between Ryanville and the Gatineau, which would be crossed at a point about 11 miles south of Long Lake by means of a bridge having a span of 150 feet. The estimate has been got out on the assumption that provision is made for two pipes across the bridge, each to be able to carry 25,000,000 gallons per diem, and the pipes would be housed in and surrounded with sawdust or some other suitable insulating material to prevent freezing in winter where they are brought over the bridge. After crossing the Gatineau the pipe would proceed in a south-westerly direction, joining the C.P.R. about half a mile south of Low Station, passing through cultivated land and another cedar swamp between the river and this point, the total length of the pipe from Long Lake to the C.P.R. being about 16 miles. From Low as far as Chelsea, a distance of about 24 miles, the pipe track would be in close proximity to the C.P.R., and this portion of the route would not be so easy from the point of view of pipe-laying, a good number of minor work, such as bridges, stream crossing and culverts being required. At Chelsea the pipe would leave the C.P.R. and proceed nearly due south, passing close to Old Chelsea to the service reservoir, a distance of about four and a half miles. The service reservoir is located in the hills, about two and a half miles south of Old Chelsea and four miles north-west of Hull. The portion of the track between the C.P.R. and the service reservoir would be through cultivated land.

Service Reservoir.—The function of this reservoir is two-fold:—

1. To provide against a water famine in the town should the water have to be cut off in the aqueduct to allow of repairs being executed.

2. To meet the daily fluctuations in demand, as the water supplied to a town varies throughout the day, the maximum draught or peak load being nearly twice the average. A reserve must also be available in case of fire.

It is far more economical to lay out a gravity scheme of this nature so as to include a service reservoir of ample size than to lay a duplicate main when the aqueduct is long and a good site can be found for the reservoir at a suitable level. Fortunately, a good site at a suitable level has been found where the water would be stored in a basin having a flat bottom and surrounded by hills. The bottom of the reservoir varies from about 410 to 416 feet above datum, and by means of three small dams the water would be held up to a level of 545 feet above datum. The water area would be about 54 acres, and one foot in depth would represent approximately 15,000,000 gallons. The probable variation in water level to meet the daily fluctuation in demand would, therefore, be less than one foot. The contents of the reservoir between the level of 420 and 445 feet above datum would amount to about 295,000,000 gallons, and represents a reserve of about 12 days' supply, which is very ample when compared with what is allowed by other cities. The static pressure given by this reservoir would represent 118 pounds at the pumping station, or 81 pounds at Parliament Hill, and is about the maximum pressure that the house fittings would stand in the lower parts of the city.

Pipes from the Service Reservoir to the City.—These pipes should be designed so as to be able to discharge for short periods during the day a much larger quantity than the pipes from the source to the service reservoir. The maximum rate of consumption is taken at 110 gallons per head per diem, and, if unavoidable waste is added to this, say, 40 gallons, the total maximum rate of consumption would amount to 150 gallons per capita per diem. To this should be added the amount required for, say, 25 fire streams, which would be equivalent to a rate of discharge of another 36 gallons per head per diem; so that the pipes should be designed to be capable of discharging 186 gallons per capita per diem as a peak load. On the basis of a population of 250,000 persons the above rate would represent a discharge of 46½ million gallons per diem. Two 51-inch pipes would deal with this peak load, so that when the population increased to 250,000 persons the pressure would not fall below 110 pounds at the existing pumping station, even should a serious fire occur during the period when the maximum demand was being made for water for domestic purposes.

After leaving the service reservoir the pipes would be laid through cultivated land to the west side of Hull Station so as to cross under the proposed Georgian Bay Canal below the level of the bottom of that channel. If the canal is constructed culverts should be provided by the Canal Company at some future date to surround the pipe under the bed of the canal and allow them to be always visible for inspection. The pipes would then cross Brewery Creek about the site of the existing bridge at the end of Wright Street, and would pass through Hull till the bank of the Ottawa River is reached at a point about 1,400 feet east of the Union Bridge.

It is emphatically recommended in the report that the pipes should be carried over the Ottawa River rather than under it, so as to facilitate easy inspection and maintenance in good condition at all times. A tunnel is not recommended, owing to the peculiar rock formation, which, being full of joints and crevices, would have occasioned considerable difficulty in driving.

There are four channels which would necessitate: a bridge about 300 feet long on the Hull side of the river, a bridge 500 feet long over the main channel of the river, two short spans, one of 80 and one of 120 feet, the latter crossing the tail-race canal from the present pumping station. For the longest spans 500 feet and 300 feet in length, it is proposed to carry the pipes on suspension bridges, which can be made light and elegant

in design at a smaller cost than any other form of bridge for these spans. Changes of temperature cause the decking of such bridges to rise and fall considerably at the centre of the span, and allowance for this will, of course, have to be made by the employment of a special form of joint to prevent racking of the pipes. In order to prevent the freezing of the water in the pipes where they would be exposed to the air, there is the alternative of insulating them with a sufficient thickness of material and of carrying them within a light timber structure or shed, special provision being made to warm the air inside the shed in winter. The latter alternative permits of a lighter and cheaper bridge for the long spans, and the estimate is based on this assumption. Where the pipes cross the two narrow channels the box girder form of bridge would be suitable, the pipes being laid in the interior of the box girder, the bridges being designed so as to interfere as little as possible with the existing surface of the ground and of sufficient strength to carry four 51-inch diameter pipes, which would give a maximum discharge at the rate of 93,000,000 gallons per diem without material loss of head between the service reservoir and the city.

The following estimate is based upon the proposals mentioned in the report:—

Head Works.	
Dam at outlet of Mitchell's Lake to raise water surface to 570 feet	$ 130,180
Clearing and burning area to be submerged	128,000
Tunnel between Pemichangaw and Long Lake, including shafts, etc.—3,000 lin. ft.	119,630
Outlet works at Long Lake—straining tower, etc.	43,660
Smaller works about lakes, including subsidiary dams at depressions in height of land, temporary works at Pemichangaw, dowering and clearing Long Lake, etc.	72,000
Aqueduct to Service Reservoir.	
54-in. steel main, 7-16-in. thick, between outlet tower and service reservoir—235,000 lin. ft.	4,314,080
Bridge on Gatineau River	30,000
Various smaller stream crossings and culverts	110,000
Service Reservoir.	
Dams	212,150
Clearing and stripping site	21,460
Inlet and outlet works	26,600
Aqueduct Service Reservoir to City.	
51-in. steel main, 7-16-in. thick between service reservoir and city—two lines of pipe, each 32,000 lin. ft.	1,101,120
Various smaller stream crossings, culverts, etc.	20,000
Bridge across the Ottawa River	180,000
Total for works	$6,508,880
Add 10 p.c. for engineering and contingencies	976,320
	$7,485,200
Land, lakes, compensation, etc.	500,000
Total	$7,985,200

If the scheme is proceeded with immediately, the system may be in use in 1917.

The City Council will have the proposal under consideration at its meeting to-morrow (October 17th, 1913).

OVER FIFTEEN HUNDRED AT ROAD CONGRESS

OVER fifteen hundred delegates attended the American Road Congress held at Detroit the first week of this month. About sixty Canadians attended the meetings, including A. W. Campbell, Deputy Minister of Railways and Canals; Honorable Dr. Reaume, Minister of Public Works of Ontario; Honorable J. E. Carron, Minister of Agriculture and Roads of Quebec Province; the members of the Ontario Highway Commission; the city engineers and some of the assistant city engineers of London, Hamilton, Toronto, Ottawa, Oshawa, Port Arthur, Orillia, St. Catharines, Windsor and Walkerville; M. D. Hallman, County Roads Superintendent, Berlin; E. A. James, engineer of the York County Highway Commission, Toronto; C. H. Keefer, C.E., Ottawa; A. T. Laing, Department of Highway Engineering, University of Toronto; A. J. MacPherson, Chairman of the Provincial Highway Commission, Regina; W. G. MacKendrick, of the Warren Bituminous Paving Co., Toronto; Controller J. W. Nelson, Ottawa; the Mayors of Port Arthur and Hamilton; Victor Pigeon, Chairman of the Road Commission of Longueuil, Que.; J. O. Sharkey, President of the Central Steel and Wire Co., Toronto; B. E. Smith, of the Barrett Manufacturing Co., Toronto; Gordon Smith, of the Barber Asphalt Paving Co., Toronto; F. M. Williamson, Engineer of Dominion Parks, Ottawa; D. P. Wagner, secretary of the Ontario Highway Commission, etc.

The attendance was better than at the Second American Road Congress, which was held in 1912 at Atlantic City, and far better than the First American Road Congress, held in 1911 at Richmond, Va. The exhibits occupied twice as much floor space as they did at Atlantic City, and were most interesting and instructive.

The asphalt interests were represented by the exhibits of the Barber Asphalt Paving Co., A. B. Chamberlain, Standard Oil Co., The Texas Co., U.S. Asphalt Refining Co., and the Warner-Quinlan Co.

The brick interests were represented by the National Paving Brick Manufacturers' Association and its constituent companies.

A number of cement companies exhibited, including the Canada Cement Co., which was the only Canadian firm having a booth, with the exception of *The Canadian Engineer.*

Several firms exhibited expansion joints or reinforcements for concrete pavements, including the American Steel and Wire Co., R. D. Baker & Co., Thomas Steel Reinforcement Co., and the Trussed Concrete Steel Co. A felt expansion joint filler was exhibited by Philip Carey Co.

Among the companies exhibiting other types of pavements or paving materials were the Asphalt Block Pavement Co., Barrett Manufacturing Co., Rudolf S. Blome Co., Dolarway Paving Co., Jennison-Wright Co. (wood block), Robeson Process Co. (Glutrin), and Warren Brothers Co.

Rock crushers, graders, rollers and other road machinery were shown by the Acme Road Machinery Co., J. D. Adams & Co., American Road Machinery Co., Austin Western Co., Climax Road Machine Co., Galion Iron Works Co., Good Roads Machinery Co., Charles Hvass & Co., Port Huron Engine and Thresher Co., Rumely Products Co., Wheeling Mold and Foundry Co., etc.

Buffalo Pitts, Holt and Wallis traction engines were at the show. Buffalo Pitts and Troy dump wagons were exhibited, a Packard motor dump wagon also being shown.

The increasing use of concrete for road construction, whether for foundations or surfaces, was indicated by the number of different makes of concrete mixers exhibited, which included the Austin, Big-an-Little, Coltrin, Eureka, Hartwick, Kent, Koehring, Lansing, Milwaukee, Rapid-Heated, VanDuzen and other makes.

Various methods of building culverts were exhibited, the cast iron pipe interests being represented by the American Car and Foundry Co. and the United States Cast Iron Pipe and Foundry Co., while corrugated metal culverts were shown by the Shannon Self-Locking Metal Culvert Co., the Portsmouth Culvert Co., the American Rolling Mills and the Galion Iron Works. Collapsible forms for concrete culverts were shown by the Concrete Form and Engine Co.

Engineering instruments were shown by the Bausch and Lomb Optical Co., and Keuffel and Esser.

Laboratories were represented by Robert W. Hunt & Co.

Gasoline engines and pumping outfits were exhibited by the New Way Motor Co., Novo Engine Co., Original Gas Engine Co., and the Whitman Agricultural Co.

Orenstein-Arthur-Koppel Co. showed models of dump cars. Steam shovels were represented by the Marion Steam Shovel Co.

The Steel Protected Concrete Co. showed the Wainwright Corner Bar, and distributed literature of the new Guelich asphalt plant. The Tarrant Manufacturing Co. exhibited various tools and other appliances for paving work, as did the Iroquois Iron Works and the Anderson Tool and Supply Co.

The exhibit of miniature models by the Office of Public Roads of the United States deserves special mention. Models of roads from the early Roman roads to the present modern types were shown. There were also models of bridges, culverts and drainage structures, rollers, crushers, etc. The New York State Highway Commission chemists were present with considerable laboratory equipment, and gave out much useful information. The United States technical papers were well represented, eleven of them having booths.

The exhibition of machinery and materials formed only one part of the work of the Congress of course, great interest being shown in the large number of valuable papers read at the meetings. Some of these papers appeared in full in last week's issue and in this issue of *The Canadian Engineer*, and others may be printed during the next few weeks; but it is understood that a complete report of the proceedings of the Congress, together with all speeches in full, will be procurable within a few weeks, for a small fee, from the secretary of the American Highway Association, J. E. Pennybacker, Colorado Bldg., Washington, D.C.

The Fourth American Road Congress will likely be held at Atlanta, Ga. The executive committee are considering the advisability of holding the Congress about January, 1915, instead of late in the fall of 1914. Many road contractors and engineers are too busy in the fall to attend the Congress, and it is also thought that possibly the lessons learned would be better remembered if the Congress were held nearer the opening of the following construction season.

ESSENTIAL FEATURES IN GOOD BRICK ROAD CONSTRUCTION.

IN the course of the paper which he read before the American Highway Association at Detroit (American Road Congress), Mr. Jas. M. McCleary, road engineer of Cuyahoga County, Ohio, refers in an interesting manner to the various events in the process of evolution which road engineering has gone through in that county from the initial stages of highway improvement to the conditions which at present mark its roads as being worthy of praise. The paper deals largely with mistakes of early brick construction, and the methods whereby they were, and may be elsewhere, overcome. Cuyahoga County possesses no peculiarities of topography or soil that are not ordinarily found in other districts and countries, and for this reason the following points as disclosed by Mr. McCleary's paper are applicable, with almost equal weight, in Canada:

In the western part of Cuyahoga County the land is so level that drainage is a difficult problem and must be given much consideration. In the southern and eastern parts, the land is so broken that to secure a feasible grade without undue expense for excavation becomes the chief difficulty. The soil varies from a sticky yellow clay in the southern and eastern sections to a sandy loam at the west. The development of the brick road, therefore, was obstructed by all the probable problems to be found elsewhere: natural and artificial soil, grades, climatic influences and the opinion of the abutting property owner.

The first brick road in the county was started in 1893 and completed in 1895. It was located on what is known as the Wooster Pike, in the southwest portion of the county. The wearing surface was of standard size brick, eight feet in width, tar filled, placed between stone curbs, $3'' \times 15''$, and resting upon a six-inch broken stone base. The pavement was placed upon one side of the roadway with a graded earth drive occupying the balance of the width. No drainage was provided and really nothing of detail was taken into consideration. No requirement in the specifications dealt with the quality of the stone, and the result was that field stone was used for base, and of such consistency that, when the roller had done its work, one might think that sand ballast had been used. Upon this the cushion was placed without compression and then the brick. As to the filler, no one could have told its composition at the end of six years, so little of it could be found.

The pavement being but eight feet in width, all the traffic came in one place. Lack of bond and absence of uniform support caused a depression to appear. In the wet season this rut or groove filled with water which soaked through the base, creating a worse condition from day to day during the damp seasons. The colder weather brought upheavals and such havoc that many sections of the so-called improvement were a hindrance rather than an aid to the traffic.

These defects were not repaired, owing to the fact that the law under which these improvements were made permitted no expenditure for maintenance. In 1898 this legislative flaw was remedied, but for five years there was no chance to palliate the badness of our methods nor to interfere with the increasing delapidation which constituted the chief value of this road—the value of a horrible example.

The next road laid was South Woodland. This is in the eastern section of the country. Again the wearing surface was eight feet in width, tar filled, and placed be-

tween flush stone curbs on a six-inch broken stone base. We had learned, in a small way, from our first mistakes and placed a six-inch drainage tile beneath the centre of the roadway. But on account of the soft filler and imperfect preparation for carrying off the water, but little improvement in the result was realized. An uneven settlement of the base soon resulted in roughness.

Lorain Road, our next installation, was built sixteen feet wide, tar filled, and resting upon a crushed stone and slag base between flush curbs, with drain tile beneath each curb. Subjected to an unusually heavy traffic, the almost inevitable result of such construction must be extensive repairs, amounting almost to reconstruction.

Our next great forward step occurred when the tar filler gave way to a grout filler composed of one part sand and one part cement. This plan was followed until 1905 with success, at least in comparison with previous experiences. The cement filler alone could not cure all of the defects due to inferior drainage and frost action. Another step was therefore decided upon—the inclusion in the specifications of a requirement for a 4-inch concrete foundation which, of course, increased the price. The increased cost brought immediate opposition, resulting in a temporary return to broken stone or slag base until 1908, when concrete was again adopted as a foundation and continued up to the present time.

Since 1908 it has been the policy not merely to conform to the chief essentials of brick paving, which are: (1) properly prepared subfoundation, (2) smoothly finished concrete base, (3) compressed sand cushion, (4) laying of good brick, (5) application of the cement filler to the joints; but to attach importance to minor details of approved manner and method of construction. Doubtless we have not even yet given weight to certain details advocated by some of the more painstaking students of brick road construction in the country.

A satisfactory plan for an average rural pavement may include a paved portion anywhere from 9 to 16 feet in width, the width being controlled by the amount of traffic to which the road is subjected. A dirt or gravel macadam should occupy the balance or unpaved portion of width. Whatever dimensions are adopted, the surface drainage should be over the pavement toward a ditch on the side of the road closest to the pavement, eliminating a crown from the paved portion. The unpaved portion should be drained in the opposite direction.

Immediately you ask: "Why a dirt road?" The best answer is, "Ask the farmer," and he will tell you to ask the horse.

The engineer will save himself much trouble if he holds to such a grade line as will entail minimum depths of fill. This is not always possible and it is the larger fills that call for the most extreme care. It behooves the engineer to see that his specifications contain a clause calling for the fill to be put in layers of not more than 6-inch thickness and each layer compacted with a roller not exceeding 10 tons in weight. This clause must be enforced with rigidity.

Puddling is the one method that can be followed successfully in the treatment of old fills. The surface of the road should be broken and dirt removed from the centre to the sides. At right angles to this trench, shorter trenches should be dug at intervals of 25 feet, forming a rectangular vat. Pump water into these compartments and allow it to stand until it has leaked its way into the fill. This will disclose the weak spots and the engineer can take care of them as he thinks best.

The drainage of the graded portion of the road is of first necessity. Whatever plan is adopted, the one that will most nearly maintain the sub-structure free from moisture below the frost line is the ideal condition to be sought. This means that you must not merely drain the road bed, but adequate side ditches must be provided to carry off promptly the accumulated water. In the preparation of a sub-base the only debatable proposition is the purpose of rolling. Common practice, including the use of a very heavy roller, has been founded upon the theory of compacting the soil to as great a depth as possible. This can do no harm, but the writer believes that the chief purpose of rolling is accomplished when the weak or spouty places in the soil are revealed so that the engineer can treat them as he sees fit. For this purpose, a roller weighing from 8 to 10 tons answers every requirement.

Preceding the final preparation of the sub-base the curbs must be placed. In case of most of our rural work, curbs are placed flush with the surface of the completed pavement.

With curb set and base prepared, the next step is the placement of the concrete base, which with our roads has been 4 inches in depth. In specifying the proportions, a mixture of 1:3:5 with a permissible variation according to the size of the aggregates which will most nearly fill the voids, meets every necessity. To meet this variableness, which obtains with almost every job, it is necessary to specify the size of the coarse aggregate, but not the amount, requiring only so much of the coarse aggregate to be used as shall leave the concrete most nearly free from voids. This, instead of an inflexible rule of proportions, will assure a condition of concrete whereby a smooth surface is easily attained. A smooth surface must be had, for upon that much of efficiency and durableness of the wearing surface depends. It assures in the next step a requirement of equal importance, that of placing the sand cushion of uniform fill and of uniform density.

While it is possible that often too much importance is placed upon the ability of the sand cushion to afford a resiliency or absorb shock, it is unquestionably a necessity for the purpose of bringing the wearing surface of the brick to a perfect plane, by neutralizing the unevenness and lack of uniformity of the brick. No one will question but that the support of the wearing surface provided for by this sand cushion must be uniform. It is therefore necessary to compress and bring to a like density every part of this cushion. Dropping the sand cushion on to the base from dump wagons and leaving the bottom portion of the load untouched before striking off with a template is objectionable, as it renders the hand rolling difficult by having a dense pile and a loose pile to contend with, the roller spanning the looser portion. It is better to spread the sand entirely by shovels, then by rolling and striking off and re-rolling, even a third time. This brings the cushion to a condition of compactness and even density that will not only furnish an even support to the entire pavement, but will prevent the sand from flowing up into the joints of the brick when the brick surface is rolled. While it is not necessary for this cushion sand to be entirely free from soil and vegetable matter, it should be nearly so, otherwise its density cannot be maintained.

Respecting the laying of the brick, the following points are noted by Mr. McCleary as important:—

(1) See that the lugs are turned one way.

(2) Make certain that the joints are broken so that one-third or more of the brick of one course overlaps the brick of the next course.

(3) Be sure that every fourth course is driven up to a straight line.

(4) For the sake of appearance, keep the line of the brick at right angles with the curb.

Next in order is culling. Care should be taken to see that all soft brick or brick that are burned too hard are removed. Those so heavily kiln-marked that they will cause unevenness in the pavement should be turned. Caution should be exercised in this, for many a kiln-marked brick is thrown out which, if allowed to remain would have been of more value to the pavement than others that are retained.

After the brick are thus placed in the street, their slight unevenness should be ironed out by the use of a roller not exceeding 5 tons in weight. If a horse roller is used at all, it should have a diameter of at least 5 feet. Rolling should begin on one side and pursue a course parallel to the curb. The roller should return over the same course. The next trip should lap the first, the roller again returning over the same course. This should continue until the centre of the pavement has been reached when the roller should be moved to the opposite curb and continue as before until the centre is reached from the other side.

The roller should then start at one side and work diagonally across the pavement. This diagonal rolling will have a tendency to bed the brick in such a manner as to avoid "rocker." The pavement should then be culled again for broken brick, after which it should be hand-rammed with a paver rammer weighing not less than 50 pounds. Interpose a plank not less than 6 feet long, 10 inches wide and 2 inches thick, between the surface of the pavement and the rammer. The plank should be laid parallel to the curb.

For filling joints, the next process in order, use a grout filler composed of equal parts of sand and cement. It seems hardly necessary to state that the cement should meet the standard specifications for Portland cement as adopted by the American Society for Testing Materials. The sand with which we have had much success has been taken from the lake and, although not very sharp, is nevertheless fine and clean and has given good results. In any event the sand to be used should be free from sewage, acid or soil, and should be sharp and fine.

A watertight box, standing on uneven legs so as to afford a "lower corner," should be used as a receptacle for the grout. In it place one cubic foot of sand and one bag of cement, mixing the mass until it assumes a uniform color. Add water and stir the mixture until it assumes the consistency of thin cream. The mixture should then be applied to the pavement by means of scoop shovels and thoroughly swept into the joints. After this has had sufficient time for setting a second coat, slightly thicker, should be applied and later a third coat, which will assure filled joints. This last coat should be worked either with a specially prepared broom or a rubber squeegee, and swept across the joints at an angle of 45 degrees.

After the initial set has taken place, the pavement should be covered with a half inch or more of sand and this kept saturated with water for at least 5 days. The pavement should not be opened to traffic for at least 10 days.

We have not undertaken any special provision against possible thermal effect, such as contraction and expansion due to low and high temperatures, but have relied mainly upon the condition of our structure by avoiding moisture underneath the roadway and by an endeavor to have our cement-filler of the greatest possible strength. These provisions, together with a rigid curb, enables us to hold in compression, the expansion occurring in our narrow roadways. In this respect, we have not been entirely successful. A few cracks in the pavement have appeared, but so far, they have not ravelled out so as to injure the traffic worth of the road, and have not been thought of sufficient importance to require repairs.

COAST TO COAST.

Montreal, Que.—The fourth and last 270-foot span of the C.P.R. Lachine bridge has been placed in position.

Toronto, Ont.—The Hon. Robert Rogers, when inspecting the city harbor, made the statement that it is planned to have the Great Lakes watercourse for ocean freighters completed in 1918.

Regina, Sask.—The sewer work contracted for by the Regina City Council early in the year is nearly all completed, and already the city engineer and his staff are busily engaged on planning the extensions for next year.

Vancouver, B.C.—The contractors have announced that within 30 days, work will commence on the erection of the Dominion Government dock in East Vancouver, which has let at an estimate of three-quarters of a million dollars.

Edmonton, Alta.—The city council has instructed the city commissioners to apply to the Dominion Government to have lands reserved for the source of the city's gas supply in the gas district at Vegreville. A pipe line of 90 miles, the cost of which would be $946,500, would be necessary to carry the supply to Edmonton.

Saskatoon, Sask.—At the recent convention of Canadian municipalities held at Saskatoon, a movement was set on foot to urge the establishment of a local government board, whose particular function will be to keep in constant touch with the finances of each city and municipality within its jurisdiction on lines similar to the system in vogue in England.

Montreal, Que.—The first C.N.R. train to make the through trip from Toronto to Quebec, covered the road early in October, bearing the president and Lady Mackenzie to the "Royal Edward" steamship. The track is pronounced in first-class condition, though regular passenger service will not commence until the ballasting is fully completed.

Ottawa, Ont.—The Conservation Commission will support the recommendation of the Ontario Municipal Electric Association that the water powers along the rivers and canals of Ontario be handed over to the Ontario Hydro-Electric Commission. It has been urging this policy for some time, though it is not particular whether the development is carried out by the federal or by the provincial government.

Edmonton, Alta.—A deputation of 70 farmers called upon Premier Sifton to ask that he urge upon the government the necessity of considering the question of assisting in the building of light railways to connect with settled districts removed from main lines of railway. The deputation was particularly concerned with the construction of a railway in Blindman Valley in the Lacombe and Ponoka districts.

Montreal, Que.—Mr. T. S. Darling has stated that between the 20th and 30th of December, the completion of the tunnel through the mountain will be announced. Two thousand feet of distance remain to be cut, but there has been little trouble so far and none anticipated until the work is

finished. No difficulty with respect to air pressure has been experienced, since the tunnel does not lie under a river.

Victoria, B.C.—An important operation was achieved in connection with the improvement work in the Inner Harbor, when 700 tons of rock were displaced at a single charge. This was accomplished at the Soughees rock where drilling and blasting operations are being carried on at present. The elimination of several of the dangerous rocks has removed the menace to shipping, which has prevented large vessels from entering the Inner Harbor.

Montreal, Que.—At the annual meeting of the Grand Trunk Pacific Railway Company, report on the construction of the main line to the Pacific coast showed that the work has reached mile 1,204 west of Winnipeg, and mile 305 east from Prince Rupert. This leaves a section of only 236 miles in British Columbia on which the grade is to be completed and the track laid. It is hoped to complete the connection of steel to the Pacific Ocean within the next nine months.

Coquitlam, B.C.—After four years of labor, the great dam at Coquitlam has reached completion. Its construction necessitated the tearing down of hills and the displacement of vast quantities of earth, the boring of two tunnels through solid granite and the erection of two towers. Work has ceased on all portions of the construction, the final piece of labor being the spillway, a trench 250 feet in width and 15 feet in depth, which was driven through solid rock.

Victoria, B,C,—The announcement has been made that the middle of next summer will see a new channel for the use of steamers entering and leaving Victoria's inner harbor. This channel will be one quarter of a mile wide and 20 feet deep at low water. Several patches of mud must still be cleared away, and a couple of pinnacles of rocks broken up and removed. A shorter run into the harbor will be gained by the new channel, eliminating the turns which cause considerable trouble to certain boats.

Toronto, Ont.—The acceptance of the 86-foot road standard by the Ontario Railway Board assures for Greater Toronto one of the finest road systems on the Continent. St. Clair Avenue has a width of 100 feet, and will serve as a plan for future boulevard constructions. Only at street intersections can vehicles cross from one side of the street to the other, thus obviating the difficulties to street car traffic caused by vehicular traffic in older sections of the city. Here, also, the track area has been covered by broken granite for the purpose of deadening sound.

Vancouver, B.C.—Another bridge, the largest of its type on the mountain section of the C.N.R., has been completed. It stretches for 760 feet over Stoyama Creek, and consists of seven steel spans resting on six concrete pedestals. Surmounting the pedestals are six towers, each 40 feet in width. Track is now being laid over the bridge and beyond it westwards until Nine Mile Creek is reached, where another steel viaduct, 300 feet long, having three towers and two spans, will be constructed. Still further west, between Nine Mile Creek and Cisco, smaller steel bridges will be erected over obstructing creeks and gullies.

Regina, Sask.—City Engineer McArthur has decided on a novel plan to keep the roadways of Regina in proper condi tion. The assistance of the boy scouts has been enrolled Boy scouts patrol different sections of the city at stated times and report where improvement is needed in the roads. These reports are handed over to what is now called the "road repair gang." This gang of men is employed for the specific purposes of making repairs, and is kept busily engaged fixing up the bad spots reported by the boy scouts. It is expected that by this system the roads throughout the entire city will be in good repair by freeze-up.

Vancouver, B.C.—The opening of Kingsway, the newly-paved 12-mile highway connecting Vancouver with New Westminster and the municipalities of South Vancouver and Burnaby, was celebrated recently by a program of ceremonies comprising an imposing procession of city and municipal officials carried by 563 automobiles bountifully decorated with flags as far as the corner of Kingsway and Boundary Road, where speeches were given by the Mayor, Reeves and the Hon. Thos. Taylor. He formally declared the highway open to traffic, congratulated the cities and municipalities upon the highway construction, and outlined the possibility of a circular road paved from Vancouver to New Westminster, via Kingsway, returning by the river road. Amidst the enthusiastic cheering of the great crowd assembled, the procession re-formed and continued along the highway to the Royal city.

Medicine Hat, Alta.—The Southern Alberta Land Company has been carrying out an irrigation project that will water the greater part of 400,000 acres of excellent land in Southern Alberta. They have engaged in the work Mr. David W. Hays as chief engineer with a force of about 500 men. One of the greatest feats in connection with the scheme will be the construction of one of the longest tunnels for carrying water in Western Canada, as well as one of the largest in diameter, its cross-section being 100 feet. The tunnel will commence at a point three miles south of Lake McGregor, and extend about two miles along the lower end of the Snake Valley. It will cut off five miles along the main ditch from the lake, which is the main source of supply. When completed it is estimated that it will carry 1,300 second feet, or 1,300 cubic feet will pass a given point every second.

Edmonton, Alta.—Much discussion is being given to the deficits which appear every month in the earnings of the city's street railway department. Among other recommendations, Cost Engineer Bowness has suggested that an immediate investigation of power rates be made to settle the basis of rate and the method of measuring power delivered, which is now indefinite and unsatisfactory. The rates charged by the power department are admitted to be excessive. To reduce the power charges so as to supply direct current to the street railway company at the exact cost of production would alter the monthly report of Mr. Woodroofe, superintendent of the street railway department, and deficits would be eliminated. The power department would show a smaller surplus with the carrying out of the recommendation, but a report showing a balance on the right side in both departments would make more pleasant reading for the citizens, the owners of these concerns.

PERSONAL.

W. G. CHACE, B.A.Sc., of the firm of Kerry and Chace, Limited (until recently, Smith, Kerry and Chace), has been appointed chief engineer of the entire construction of the Greater Winnipeg water system.

W. S. HARVEY, mentioned in our personal column on August 21st, as acting city engineer of Lethbridge, Alta., succeeding A. C. D. Blanchard, resigned, has just been appointed to the position of city engineer.

ERNST POENSGEN, manager of the Tube Department of the Phœnix Steel Works of Dusseldorf, Germany, returned home last week. He spent some time at Montreal with his firm's Canadian agents, Gerald Lomer, Limited.

DR. CARL IMHOFF, eminent in the design of system and apparatus for scientific sewage disposal was a visitor in Toronto last week, and made a careful tour of inspection over the sewage disposal plant at Morley Avenue.

J. H. FUERTES, civil and sanitary engineer of New York, and a member of the board of experts, who reported recently on the Shoal Lake Water Supply scheme for Winnipeg (See *The Canadian Engineer*, September 11th, 1913), has been appointed consulting engineer for the work.

C. R. KRUMBIEGEL has been appointed Chief Engineer for Canada for Deutsche Maschinenfabrik, A.G., Duisburg, Germany. Mr. Krumbiegel has been on the engineering staff of this firm for a number of years and has had experience, not only in Germany, but in the United States as well. He will be permanently located in the office of the firm's Canadian agents, Gerald Lomer, Limited, Fraser Building, Montreal.

R. H. REYNOLDS, was last week appointed a commissioner to act in connection with the Shoal Lake water supply system for Winnipeg, upon which construction work will begin immediately. It is stated that the other commissioners will not be appointed for some little time. Mr. Reynolds was for some years assistant city engineer under City Engineer Ruttan, and when he left in 1907 was succeeded by R. D. Wilson, who still holds that position. For a number of years he was engaged in mining pursuits, and is at present a resident of Victoria, B.C.

J. E. PENNYBACKER, secretary of the American Highway Association, was in Toronto this week making preparations for his new work as consulting expert to the Ontario Highway Commission. Mr. Pennybacker was educated at West Virginia University and the University of Georgetown, graduating in law in 1900. After four years' practice with a railroad corporation, he was appointed chief clerk of the United States Office of Public Roads. Some particularly able work that he did in gathering economic data regarding roads, attracted the attention of the Cabinet, and he was appointed Chief of Road Management. When the American Highway Association was formed about two years ago, Mr. Pennybacker resigned his government position to become its permanent secretary. On the recommendation of Director Page of the United States Office of Public Roads, Mr. Pennybacker was also appointed as consulting expert to the Joint Congressional Committee on Road Legislation. Mr. Pennybacker gave valuable assistance to the Committee which reached the notice of the chairman of the Ontario Highway Commission. At the request of the Ontario Government, the American Highway Association permitted Mr. Pennybacker to act as consultant to Ontario Highway Commission. The vast amount of data that he has gathered during the past ten years on every phase of road legislation and road construction, will undoubtedly help the Ontario Commissioners in framing a model Highway Bill and in organizing an ideal Highway Department.

OBITUARY.

GEO. G. ROSE, C.E., a member of the engineering staff of the Cornwall Canal, and a native of Morrisburg, Ont., died last week at Cornwall. Mr. Rose was a graduate of the Royal Military College, Kingston, and was connected with the Marine Department, Ottawa. Fifteen years ago he was in charge of the construction of a part of the Rapide du Plat Canal. He was 63 years of age.

JAMES HARRISON, a member of the engineering staff of the York County Road Commission, died suddenly in Woodbridge, Ont., last week. Deceased was overcome by a paralytic stroke, and a record run to a city hospital proved in vain. Although not a graduate, Mr. Harrison was a member of the 1887 class in Civil Engineering at the School of Practical Science, Toronto

EXTENSIONS TO ELECTRICAL FIRM.

Contracts have just been placed by the Eugene Phillips Electrical Works of Montreal for a large amount of new machinery with which to equip the new quarter of a million dollar extension to their Montreal plant. There has already been installed in this extension all of the machinery that had been previously used by the Stromberg-Carlson Telephone Manufacturing Company of Rochester, New York, in their telephone-cable making branch. This branch of the Stromberg-Carlson business was purchased outright by the Montreal firm, which is now in a position to bid on very large contracts for telephone cable. The capacity for making other cable will also be greatly increased, and the contracts recently let for machinery will widen the field of the company's activities.

COAL TESTING.

At the October meeting of the Cleveland Engineering Society, held on 14th inst., Dr. W. G. Wilcox, of the Cleveland Research and Testing Laboratories, presented an illustrated paper on "Coal Testing." Another meeting is being held on October 21st, when Mr. Jos. R. Poe, Structural Engineer, the Wellman, Seaver, Morgan Company, will give a paper on "The Practical Side of Steel Structures."

OTTAWA BRANCH—CANADIAN SOCIETY OF CIVIL ENGINEERS.

At the annual meeting on October 2nd, of the Ottawa Branch of the Canadian Society of Civil Engineers, Mr. Geo. A. Mountain was appointed chairman of the branch. Meetings for the presentation and discussion of papers will be held on the first and third Thursdays of the fall and winter months, the other Thursday evenings to be devoted to informal or business meetings. Mr. R. F. Uniacke is the retiring chairman.

COMING MEETINGS.

CANADIAN SOCIETY OF CIVIL ENGINEERS.—The first monthly meeting of the Society for the winter session will be held on Thursday, the 16th inst., at 8.15 p.m. An illustrated address on Elevator Construction will be delivered by Mr. Jas Spelman, M.Can.Soc. C.E.

NATIONAL SOCIETY FOR PROMOTION OF INDUSTRIAL EDUCATION.—Annual convention to be held at Grand Rapids, Mich., October 19th to 25th. Secretary, C. A. Prosser, 105 E. 22nd Street, New York City.

AMERICAN MINING CONGRESS.—Annual convention will be held at Philadelphia, Pa., October 20th to 25th. Secretary, J. Callbreath, Majestic Building, Denver, Colo.

AMERICAN RAILWAY BRIDGE AND BUILDING ASSOCIATION.—Annual convention will be held at Montreal, Que., October 21st to 23rd. Secretary, C. A. Lichty, 319 N. Waller Avenue, Chicago, Ill.

UNITED STATES GOOD ROADS ASSOCIATION.—Convention will be held at St. Louis, Mo., November 10th to 15th. Secretary, J. A. Rountree, L021 Brown-Marx Building, Birmingham, Ala.

NATIONAL MUNICIPAL LEAGUE.—Annual meeting will be held in Toronto, November 12-15. Secretary, C. R. Woodruff, 705 North American Building, Philadelphia, Pa.

AMERICAN ROAD BUILDERS' ASSOCIATION.—Tenth Annual Convention to be held in First Regiment Armory Building, Philadelphia, Pa., December 9th to 12th. Secretary, E. L. Powers, 150 Nassau Street, New York, N.Y.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for small fee.

20447—September 30—Authorizing C.P.R. to open for traffic that portion of its Swift Current North-West Branch from Cabri, mileage 34.8, to Westerham, near mileage 94.0, a distance of 59.2 miles. And relieving company of speed limitation of fifteen miles an hour between mileages 34.8 and 33.0, imposed under Order No. 16869, dated June 25th, 1912.

20448—September 29—Authorizing Lachine, Jacques Cartier, and Maisonneuve Ry. Co., to take certain lands in city of Montreal, P.Q., required for diversion of Harbor Street; said lands being required to give effect to Order No. 16181, dated March 28, 1912, authorizing the crossing of certain streets in Montreal, including diversion of Harbor Street.

20449—September 29—Directing that crossing of Wallace Ave., Toronto, by G.T.R., be protected by gates operated by day and night watchmen appointed by Ry. Co.; cost of installing and maintaining gates and wages of watchmen be borne and paid by city of Toronto; work to be completed within 60 days from date of this Order, and rescinding Order No. 9247, dated January 12th, 1910; such revision to take effect upon installation of gates herein required to be provided.

20450—September 26—Authorizing G.T.R. to construct siding, and spur therefrom, into premises of Ogilvie Flour Mills Co., Limited, west of Mill Street, Montreal, Que., subject to and upon certain conditions.

20451—September 27—Authorizing G.T.R. to construct additional track, or siding, commencing at a point on its railway west of Gore Street, Stratford, Ont., thence extending easterly across Gore Street. Siding to be completed within three months from date of this Order.

20452—September 29—Extending, for a period of three months from date of this Order, time within which G.T.R. construct branch lines of railway and additional tracks in the village of Port Colborne, Ont., authorized under Order No. 19535, dated June 4th, 1913.

20453—September 29—Authorizing C.N.O.R. to construct, subject to conditions contained in consent of Montreal Tramways Company, dated August 26th, 1913, proposed temporary grade on its Montreal-Hawkesbury Line from mileage 46.69 to 48.62, to be used for construction purposes only for a period of one year; and to cross on said temporary grade for said period, the Monkland Boulevard, Bois Franc Road, Montreal Park and Island Ry., and St. Laurent Road.

20454—September 30—Authorizing C.N.R. to construct across twenty-two (22) highways on its Goose Isle Branch, Manitoba.

20455—September 30—Authorizing C.L.O. & W. Ry. (C.P.R.) to construct, at grade, across side road in Lot 14, Con. 3, Tp. of Bathurst, Ont.; and to construct temporary diversion of said railway at mileage 2.1.

20456—September 30—Authorizing C.L.O. & W. Ry. to construct ballast pit spur line, by means of grade crossing, across road allowance between Lots 10 and 11, Con. 1, Tp. Murray, Co. Northumberland, Ont., at mileage 0.09 on ballast pit spur.

20457—September 30—Approving, subject to provisions of sub-section 2 of Sec. 327, and sub-section 1 of Sec. 331, of Ry. Act, maximum tolls to be charged for passengers for all distances on C.P.R. lines in Canada now in operation or under construction, as specified in Co.'s Standard Passenger Tariff, C.R.C. No. 2279, dated at Montreal, Aug. 12th, 1913, to become effective Sept. 1st, 1913, namely: three cents (3c.) per mile east of and including company's railway between Macleod, Calgary, and Edmonton, Alta., and four cents (4c.) per mile west of and including Macleod and Calgary, said tariff being a consolidation of company's approved Standard Passenger Tariffs, C.R.C. Nos. W. 38, and E. 664.

20458—September 30—Directing C.N.O.R. to provide and construct suitable farm-crossing and cattle-pass where it crosses lands of William and Robert Wilson, in Lot 26, Con. B, Tp. Westmeath, Co. Renfrew, Ont., subject to and upon certain conditions.

20459—September 11—Authorizing C.P.R. to construct spur for Northern Elevator Co., Limited, Winnipeg, Man., from a point on existing spur on Sutherland Ave., subject to and upon certain conditions.

20460—September 30—Authorizing G.T.P. Ry. to construct wye track at mileage 29 west of Yellowhead Pass, Cariboo District, B.C.; and rescinding Order No. 17618, dated September 25th, 1912, made herein.

20461—September 30—Extending, for a period of thirty days from date of this Order, time within which G.T.R. complete culvert under its tracks, Tp. Tecumseh, Ont., authorized by Order No. 19988, dated Aug. 5th, 1913.

20462—October 2—Declaring that joint tariff of Alta. Ry. and Irrigation Co., C.R.C. No. 165 is lawfully in effect; and that Supplement No. 16 thereto, published and filed by C.P.R. to take effect August 18th, 1913, is disallowed. Board will be prepared to consider an application for annulment of said C.R.C., No. 165 on publication and filing by C.P.R. of local and joint tariffs of rates from Lethbridge, and from points on line of Alta. Ry. and Irrigation Co., via Lethbridge, which shall not be greater than those shown in said C.R.C., No. 165, via Coutts, to points in B.C., on G.N.R. and C.P.R., to which the rates of said C.R.C., No. 165 are now lower than via C.P.R. from Lethbridge, having regard to provisions of Ry. Act.

20463—September 30—Establishing collection and delivery limits of the Dominion Express Co., in town of Swift Current, Sask.

20464—October 1—Authorizing Edmonton, Dunvegan and B.C. Ry., to construct across two highways—namely, 1. between N.E. ¼ Sec. 13-74-16, W. 5 M., and N.W. ¼ 18-74-15, W. 5 M.; 2. N.E. ¼ Sec. 13-74-16, W. 5 M., Province of Alberta.

20465—October 1—Extending, for a period of 60 days from date of this order, time within which G.T.R. install electric bell at crossing of Mill Street, Milverton, Ont., required under Order No. 19893, dated July 24th, 1913.

20466—October 1—Authorizing G.T.R. to construct siding into premises of the Ham and Nott Co., Limited, on Block "C." north of Bruce Street, city of Brantford, Ontario.

20467—September 30—Authorizing G.T.P. Ry. to construct spur for the Park Lumber and Planing Mills, Limited, in Block 10, Cromdale Subdivision of River Lot 24, Edmonton, Alta.

20468—October 2—Approving location C.P.R. stations on Port McNicoll Subdivision, Ont. Div.—namely, 1, Lot 28, Con. 3, Tp. Ops, Co. Victoria, Ont., at Cambray, mileage 22.78, and 2, at Franklin, mileage 6.3, Lot 22, Con. 12, Tp. Manvers, Co. Durham, Ontario.

20469—October 1—Authorizing C.P.R. to construct spur into premises of G. F. Stephens and Co., Limited, on Lot 64, parish of St. Boniface, Winnipeg, Man., subject to and upon certain conditions.

20470—October 1—Authorizing C.P.R. to construct, subject to terms of consents of town of Swift Current, dated May 23rd and September 9th, 1913, spur for Swift Current Grocery Co., Limited, and Winnipeg Paint and Glass Co., Limited, Swift Current, Saskatchewan.

20471—October 1—Approving location C.P.R. station at Musquash, parish of Musquash, Co. St. John, N.B., at mileage 66.41 on Co.'s Shore Line Subdivision, Atlantic Div. Dist. No. 1.

20472—September 30—Authorizing C.P.R. to construct Weyburn-Stirling Branch Line across twenty-nine (29) high-

ways between mileage 37.94 and 65.20 (zero of said mileage being at Stirling).

20473—October 1—Authorizing C.P.R. to construct sidings for Messrs. McGregor and McIntyre, Toronto, Ont.

20474—October 2—Authorizing Commissioners of Transcontinental Ry., to make, subject to terms of consent of C.P.R., siding connection with C.P.R. tracks to shop site of applicants, in Lot Cadastral, No. 2345, parish of St. Sauveur, Co. Quebec, Que.

20475—October 2—Authorizing G.T.R. to use and operate Bridge over Richelieu River, at Mile Post 8.73 on Thirtieth Dist., near Lacolle Junction, authorized to be reconstructed under Order No. 15863, dated February 2nd, 1912.

20476—October 2—Authorizing C.N.O.R. to construct spur from its Rly. at Richmond Hill to property of J. H. Dunlop, Lot 24, Con. 1, Tp. Markham, Ontario.

20477—October 2—Authorizing C.P.R. to construct tracks of extension to town siding, at grade, across public road between Lots 12 and 13, Con. 3, Tp. Hagar, Dist. Sudbury, Ont.

20478—October 3—Amending Order No. 20226, by striking out figure "2" after word "Lot," wherever same appears in said Order, and inserting in its place figure "4," so as to make the Order read, "situated in Subdivision, Lot 27, Lot 4, Con. 11, Tp. Tillsonburg.

20479—October 2—Authorizing C.P.R. to change present grade crossing, necessitated by additional track (double track); and to construct, by means of grade crossing, said additional track across road allowance between Cons. 2 and 3, Tp. Toronto, at mileage 18.61 on Co.'s main line, London Subdivision.

20480—October 3—Amending Order No. 16874, dated June 26th, 1913, by striking out figures "35.5" in first line under heading Mountain Subdivision, and substituting figures "35."

20481—October 2—Directing that C.N.R. install caretaker at Sandy Lake, Man., who shall, amongst other things, keep waiting room clean and heated for arrival of passenger trains; meet passenger trains on their arrival and assist in putting on or taking off any baggage; meet local freight trains and see that package freight is properly housed; keep freight shed locked, with key at a convenient point; and deliver freight to consignees between hours of 8 a.m. and 6 p.m. Caretaker be installed not later than October 5th, 1913.

20482—October 3—Authorizing C.N.O.R. to construct bridge to carry its railway across Kiosh-Koqui Lake, Tp. Pentland, Dist. Nipissing, Ont., at mileage 186.6 from Ottawa.

20483—October 3—Directing that the sum of $4,700, deposited in a chartered bank in City of Fort William, Ont., under Order No. 18908, dated March 20th, 1913, be paid upon request of C.P.R.; and that production of a certified copy of this Order be authority to bank for such payment.

20484—October 3—Approving C.P.R. plans dated Winnipeg, May 30th, 1912, and September 10th, 1913, showing proposed location of stairway from Arlington Street Bridge to engine house at Winnipeg, Man.; and rescinding Order No. 16860, dated June 22nd, 1912.

20485—October 3—Authorizing C.P.R. to construct additional track (second track or siding) across road allowance on East Boundary of Sec. 5-9-21, W. 4 M., Alberta.

20486—October 3—Relieving G.T.R. from providing further protection at second highway crossing north of Corbeyville, Belleville and Peterboro Division, Ontario.

20487—October 4—Authorizing C.P.R. to construct, by means of a bridge, additional track of its main line, Sask. Div., Moose Jaw Subdivision, over and across road allowance between Secs. 21 and 22, Tp. 18, R. 13, W. 2 M., at mileage 52.65 on said main line. Province of Saskatchewan.

20488—October 3—Requiring C.N.R. to erect a third-class station building at St. Gregor, Sask.; work to be completed with not later than July 31st, 1914.

20489—October 2—Amending Order No. 20009, dated August 11th, 1913, by adding following clauses:—"3. That Government road allowance over C.P.R. between Sec. 1-17-27, and Sec. 6-17-26, W. 2 M., be closed subject to and upon condition that C.P.R. (Applicant Co.), provide and construct subway 40 feet wide, in the clear, just south of and adjoining its right of way, in accordance with plans submitted by Applicant Co., and approved by the city of Moose Jaw. 4. That contribution of $2,000 herein required to be paid by C.P.R. shall not become due or payable until on or after completion of subway authorized and required to be constructed under this Order."

20490—October 4—Authorizing C.P.R. to construct spur for Manitoba Cold Storage Co., Limited, city of Winnipeg, Man., subject to and upon certain conditions.

20491—October 4—Authorizing C.P.R. to use and operate, subject to condition that men be kept off sides and tops of cars when using the crossing, undercrossing shown in red on plan, during construction of Heffernan Street Bridge, Guelph, Ont. And approving and authorizing clearances as shown on plan of false work to be used at Heffernan Street Viaduct, Guelph, Ont.

20492—October 4—Authorizing city of Edmonton, Alta., to open up Spadina Avenue, across C.N.R. at rail level, within limits of city; expense of constructing and maintaining crossing to be borne and paid by applicant.

20493—October 3—Granting leave to B.C. Telephone Co., Limited, to erect its lines across G.N. Ry., on Oscar Street Abbotsford, B.C.

20494—October 1—Authorizing C.N.O.R. to construct spur to mills of Laberge and Sons, in town of Sudbury, from station 41.58.7 on connecting track between its line and Algoma Eastern Ry., and across Wilma Street.

20495—October 4—Authorizing C.P.R. to construct, at grade, spur for Tillsonburg Electric Car Co., Limited, Tillsonburg, Ont., across King Street and Sixth Street, at mileage 15.4, Port Burwell Subdivision.

20496—October 4—Approving Michigan Central R.R. plan showing bridge to be constructed under M.C.R tracks at mileage 32.98, Little Creek Drain, Tp. Tilbury West.

20497—October 4—Authorizing G.T.P. Ry. to construct spur and sidings, for Pembina Coal Co., Limited, in Secs. 19 and 30-53-7. W. 5 M., Alta.

20498—October 6—Extending collection and delivery area, in the city of Ottawa, Ont., prescribed by Order No. 16147, dated March 18th, 1913, by inserting words "including the Isolation Hospital" after words "Somerset Street," in said Order.

20499—October 6—Authorizing C.N.O.R. to construct bridge to carry its railway across Ottawa River at Fitzroy Harbor, Tp. Fitzroy and Onslow, Cos. Carleton and Pontiac, Provinces of Ontario and Quebec, at mileage 37.32 west of Ottawa, subject to terms and conditions contained in Order in Council.

20500—October 1—Authorizing C.N.O.R. to cross, at grade, Metcalfe, John, Harvey, Bourke, Jane, Durrill, Copeland, Bell, William, McIntyre, Timmons, and Nipissing streets, town of North Bay; and certain streets and avenues by means of subways. 2. construct across and divert Marion Street. 3. Closing of Cedar Street be conditional upon Co.'s extending McLaren Street, from Klock Avenue, to Home Avenue. 4. Closing of Fraser Street, be conditional upon Co.'s constructing subway 10 feet in clear width and 8 feet in height through station and under its tracks; station to be located in centre of Fraser Street to be as good, if not better, and of similar design, as Co.'s station at Belleville, Ont. 5. Co. be responsible for any damages property owners affected may be legally entitled to recover. And 6. All subways be satisfactorily drained by Applicant Co.

20501—October 6—Extending, until December 31st, 1913, time within which C.P.R. was required to construct and complete subway at Dundas Street, Woodstock, Ontario.

20502—October 6—Approving revised location C.P.R. main line, double trackage, Moose Jaw Subdivision, Sask., from a point in Sec. 27, in S.W. direction to a point in Sec. 21-18-14, W. 2 M., being from mileage 59.6 to 60.45. 2. Authorizing C.P.R. to construct road diversion across Blocks 147, 148, 149 and 150, Sec. 21, Blocks 143 and 144, Sec. 28, and across Sec. 27-18-15, W. 2 M., and to construct, by means of grade crossings main line across said diversion and across town crossing.

20503—October 6—Authorizing Government of Saskatchewan, at its own expense, to construct highway north of Sec. 28-16-15, W. 3 M., Sask., across C.P.R. Swift Current Northwesterly Branch.

20504—October 7—Amending Order No. 20190, dated August 26th, 1913, by striking out words "Suffield to Blackie" where same occur in said Order, and substituting therefor words "Weyburn-Stirling."

Barrett Specification Roofs

Last Longest—Cost Least

THE proper unit in comparing the values of roofings is the cost-per-foot-per-year-of-service.

To have a low unit cost a roofing must be—

1st. Inexpensive to build,
2d. Inexpensive to maintain, and
3d. Of great durability.

Barrett Specification Roofs are—

1st. The ***least*** expensive of all permanent roofs to build,
2d. They cost ***nothing*** to maintain, and
3d. They usually last, without repairs or leaks, ***20 years*** or over.

The net result of these three factors is a unit cost of about ¼c. per foot per year of service. This is a lower unit cost than ever attained by any other class of roofing.

Accordingly, Barrett Specification Roofs are in almost universal use on buildings such as illustrated herewith, where unit costs are intelligently studied.

Herald Building
Montreal

Architects—Brown & Vallence, Montreal
G.C. Nicholson & Co., Montreal
Roofers—Metal Shingle & Siding Co., Montreal

Copy of the Barrett Specification with tracing ready for incorporation in your building plans sent free on request. Address nearest office.

Special Note

We advise incorporating in plans the full wording of the Barrett Specification, in order to avoid any misunderstanding.

If any abbreviated form is desired however, the following is suggested.

ROOFING—Shall be a Barrett Specification Roof laid as directed in printed Specification, revised August 15, 1911, using the materials specified and subject to the inspection requirement.

RAILWAYS—STEAM AND ELECTRIC.

Cardston, Alta.—Mr. Louis Hill, head of the Great Northern Railway, who surveyed in the first week of October, the extension made by the G.N.R. in southern Alberta, announced that the company were preparing to start work at once on a branch feeder line that would open up the country in the Cardston district.

Hamilton, Ont.—Mayor Allan has announced his determination to proceed with the construction of a new incline railway if the scheme of Geo. F. Webb means that the present one must remain closed for any length of time. In the meantime a motor truck service is to be operated to convey residents to the mountain top.

Ottawa, Ont.—At the next session of Parliament an application is to be made through the Vancouver firm of solicitors, Taylor, Harvey, Grant, Stockton and Smith, for an act to incorporate a railway company to be known as the Canadian Alberta Railway Company. The line the company proposes to build will run for about 14 miles in a north-westerly direction from a point on the C.P.R., a mile west of Blairmore, Alta.

Port Arthur, Ont.—It is reported, supposedly from the Winnipeg offices, that the C.N.R. will build next year a modern car-repairing plant in connection with its local terminals at Port Arthur. This will be constructed at a cost of at least $30,000.

Quebec, Que.—Vice-president McNicoll of the C.P.R., has announced that the C.P.R. has added its signature to that of the Trans-Continental Railway and the Government to the contracts for the new Union station and railway workshops.

St. Thomas, Ont.—The city council have adopted a resolution endorsing the action of the Safety First Committee of the Michigan Central in recommending that a subway or tube be constructed under the company's local yards for the convenience and safety of the employees.

Toronto, Ont.—The promoters of the proposed Hydro-Electric railway to Whitby and Port Perry have unanimously adopted the plans and estimates submitted by the Hydro-Electric Commission at a capital cost of $2,470,776, and are considering ways and means of getting those affected by the line to approve the project and the apportionment of cost. Hon. Adam Beck pointed out to those assembled to hear the report of the commission that the construction of the line was only practicable by combining railroad operation with the distribution of electric power and light, but that the Provincial Hydro Commission would be able to supply this in towns and villages at from $5 to $17 per horsepower.

Toronto, Ont.—The Ontario Municipal and Railway Board has concluded the argument over the Annette Street line, and has ordered the completion of the line before December 1st. The city is to proceed at once with the street widening at the intersection of Law Street, plans for which must be filed at once with the board.

Vancouver, B.C.—Mr. C. L. Dickeson, manager of the White Pass and Yukon Railway route, has stated that tentative arrangements have been made between his company and the Chicago, Milwaukee and St. Paul line, for the building of that railway into Vancouver from Seattle and for the putting on of a big fleet of steamers between Vancouver and Skagway. The steamers are to handle the railway business and freight until the Pacific Great Eastern Railway is completed to Fort George, and that line has been continued to link with the White Pass Railway. This latter railway has been reported to have sent an offer to the United States Government to extend its lines into Alaska.

GARBAGE, SEWAGE AND WATER.

Edmonton, Alta.—Wholesale merchants of this city are agitating the need of a bridge or subway to be constructed across the C.N.R. tracks in the vicinity of Fourth and Fifth streets.

Edmonton, Alta.—City employees are to commence work on a 10-inch main pipe line to connect with the city's main, and to extend from 122nd Avenue to 127th Street, thence north to 129th Avenue, from which point a 6-inch pipe is to carry the city's water to the yards and shops of the E.D. and B.C. Railway. By the agreement with the city, Mr. J. D. McArthur will bear the whole cost of the work.

Fredericton, N.B.—The city Gaslight Company have asked the city for permission to lay a sewer of 12-inch terra cotta pipe from their plant along Shore Street to the river.

Hamilton, Ont.—The works committee has approved the plans designed for a system of overflow sewers to relieve the flooding which occurs during times of heavy rainfall, at an estimated cost of $650,000.

+—Montreal, Que.—The Board of Control has awarded contracts calling for an expenditure of about $60,000 in sewers. RICE AND COMPANY will lay sewers in Lacordiere Street at $13,917, in Monsabre Street at $18,968.50; PALERMO, GENTIL AND COMPANY will construct sewers in Macgregor Street at $5,560, in Edward VII. Avenue at $5,000.50, in Turenne Street at $3,442; MR. HENRI BERTRAND was given the contract for Adair Street, Ontario Street, Lafontaine Street and St. Catherine Street east of Maissoneuve for $1,691.90 each, and for George V. Avenue at $7,414.90.

MANNESMANN TUBE CO., LIMITED

BOOKLETS ON REQUEST **51 Victoria Square, MONTREAL**

Ottawa, Ont.—The Bryson Realty Company has written the city Board of Control asking that it be provided with sewer accommodation for its new building, the present system on Queen Street being inadequate. An extension of 120 feet from the Kent Street sewer is asked to accommodate as well other large buildings, which will be erected in this section.

Regina, Sask.—Tenders will be received up till October 20th, 1913, for the following works:—(1) Construction of a filter bed; (2) supply of a steel roof for filter bed; (3) supply of 9,025 concrete flooring blocks. Plans and specifications may be obtained on application to the City Engineer. R. Martin, Mayor.

Saskatoon, Sask.—Tenders will be received for the construction of sewer and water mains on Avenue O, from 17th Street to the Separate School. Plans and specifications may be obtained from the City Engineer, Geo. T. Clarke, Esq., Saskatoon, Sask.

▲—**Toronto, Ont.**—Tenders will be received up till October 21st, 1913, for the construction of a number of sewers. Specifications may be seen, and forms of tender obtained at the office of the Commissioner of Works, City Hall, Toronto. H. C. Hocken, Mayor.

+—**Toronto, Ont.**—The city will undertake the construction of the Esplanade sewer at an estimate of $11,000.

+—**Toronto, Ont.**—The GODSON CONTRACTING COMPANY have been awarded the contracts of constructing Danforth Avenue sewers at a cost of $68,800, and Morrison Avenue sewer at a cost of $17,487.

+—**Toronto, Ont.**—The contract for the construction of sewer system in Earlscourt was awarded JOHN MAGUIRE of Toronto, at a cost of $47,800.

Toronto, Ont.—Directions have been given for laying new gas mains on Geneva, Spruce and Sumach streets, these mains being inadequate for the present supply in this section of the city.

Toronto, Ont.—Commissioner Harris has notified the Board of Control that the present pumps and mains of the high level pumping station on Poplar Plains Road must be entirely rearranged. Two 20-million gallon pumps and two 7½ million gallon pumps, the steam engines and boilers necessary for operating these, and a coal and ash handling plant, are considered necessary to make provision for the water supply of the central district of the city. The steam equipment is to have a capacity of 55 million gallons, and the new steam plant will be built as an additional wing north of the electrical wing recently completed.

Vancouver, B.C.—The Burrard Peninsula Joint Sewerage Board have accepted the offer of Messrs. Brown, Shipley and Company to advance approximately $500,000 to commence the work on the sewerage system of Greater Vancouver.

Winnipeg, Man.—Tenders will be called early in 1914 for the construction of works necessary for the delivery of water from Shoal Lake to the Greater Winnipeg District. A description of the proposed works can be obtained from M. Peterson, Acting Secretary of the Administration Board, Greater Winnipeg Water District, City Hall, Winnipeg, Man.

Winnipeg, Man.—Tenders will be received up till October 17th, 1913, for the supply of a quantity of sewer pipe. Plans and specifications may be obtained from the City Engineer, 223 James Avenue, Winnipeg, Man. Signed, M. Peterson, Esq., Secretary, Board of Control.

LIGHT, HEAT AND POWER.

Edmonton, Alta.—To meet the increasing demands of the street railway department for power, it has been recommended that a new 400 k.w. street railway engine be installed to take the place of the 400 k.w. Robb engine which is said to be of no practical value. The new engine would be required to duplicate exactly the Belliss engine of 400 k.w. being used now, and should be provided with a surface condensing plant capable of dealing with the steam from both engines. The present condensing plant is of the jet type, and is extremely unsatisfactory and is costly to maintain. Plans have been prepared and a tender obtained for a duplicate engine and a suitable condensing plant at an estimate of $11,460 f.o.b., Edmonton. Mr Parsons, superintendent of the power plant, recommends its acceptance. The Board of Commissioners have not yet acted in the matter, but will consider the proposal at a future meeting.

Fredericton, N.B.—A complete modern electrical system is to be installed in the city opera house, and tenders will soon be called for the work.

Hamilton, Ont.—The ratepayers have carried with a very large majority the by-law granting the National Natural Gas Company a franchise to supply the city of Hamilton with gas.

Hamilton, Ont.—The National Natural Gas Company have made arrangements for the letting of contracts for pipe that will be used to carry gas 20 miles to this city. An engineer is to be engaged at once and everything prepared for a start on the work this year.

Maisonneuve, Que.—Tenders will be received up till October 15th, 1913, for the complete electrical installation for the erection of the public market. Plans and specifications may be obtained from Marius Dufresne, City Engineer, Maisonneuve, Que.

Medicine Hat, Alta.—Engineers and engineering contractors are interested in the survey of plans for the tunnel projected by the Southern Alberta Land Company in connection with its irrigation scheme in Southern Alberta. Tenders have been called for this work, and owing to its magnitude, numerous tenders are anticipated.

Montreal, Que.—Tenders will be received up till October 23rd, 1913, for the supply and erection at the Low Level Pumping Station, Point St. Charles, of one direct current electric generator of 35 K.W. capacity, direct, coupled to steam engine for electric lighting. Plans and specifications may be obtained from L. N. Senecal, Secretary, Board of Commissioners, Montreal, Que.

+—**Ottawa, Ont.**—The contract has been awarded the CANADIAN GENERAL ELECTRIC CO., LIMITED, by the Ottawa and Hull Power and Manufacturing Company, for the addition to their power plant of two water wheel type alternators each 6,750 K.V.A., 120 R.P.M., 2,300 volts and also of two transformers each 6,750 K.V.A., 2,300/12,000 volts.

Regina, Sask.—The citizens have shown their approval of the street lighting program as scheduled, and the Light and Power Department are free to proceed with the work as soon as can be arranged. The system requires the furnishing of standard light throughout the city, save in the business sections where double the standard will be used without extra cost to the ratepayers except for the installation of the extra lighting.

Regina, Sask.—Mr. M. L. Hovis, of Gibsonburg, Ohio, driller for the Calgary Petroleum Products Company, at Black Diamond, Alta., and Mr. W. R. Martin of Medicine Hat, will place before the Regina city council proposals for the drilling of a municipal well within the limits or close to the city's boundaries. They will also place the matter before the Moose Jaw civic authorities. In the event of failure to make an agreement with these bodies, they will organize doubtless a company for undertaking operations in this part of the province.

South Vancouver, B.C.—The members of the Greater Vancouver Sewerage Commission are making an inspection of those districts of South Vancouver mostly in need of sewerage. A motion has been passed in council for the preparation of plans and profiles for lateral sewers, and the council has announced that it will co-operate with the commissioners in working out a scheme for sewers in the municipality.

Toronto, Ont.—The program for the electrical show to be held in the Arena from November 10 to 15 is being arranged. All efforts are being put forth to make this exhibition a complete demonstration of the progress and uses of electricity in transportation, communication, surgery, mechanics, as protection against fire, as an aid to industry, and as a vital promoter in various other fields.

Westmount, Que.—Tenders will be received up till October 15th, 1913, for the supply of carbon and Tungsten incandescent lamps required by the Light and Power department. Westmount, Que. Plans and specifications may be obtained from A. F. Bell, Secretary-Treasurer, 4188 St. Catherine Street, Westmount, Que.

+—**Winnipeg, Man.**—The contract has been awarded C. H. SIMPSON AND COMPANY for the power house and heating plant of the new parliament buildings. The build-

ing of the plant will be situated on Kennedy Street, and the plant will heat the government buildings, both of the court houses, the land titles office and the provincial jail. It is to be built of stone, brick and steel and to employ the "forced hot water heating system."

Winnipeg, Man.—Controller Cockburn and Power Manager Glassco are investigating the merits of flexible and brace towers in connection with the construction of the second transmission line to be commenced this fall from Winnipeg to Point du Bois. When they have reported to the Board of Control, the tenders which have been received will be opened and the contract awarded.

BRIDGES, ROADS AND PAVEMENTS.

Moose Jaw, Sask.—The C.N.R. bridge-builders are progressing rapidly with the work upon the bridge that is to carry C.N.R. steel from South Hill to Fairford Street. The first deck is nearing completion, but until the second deck, which will permit of crossing the C.P.R. tracks without interference with traffic beneath, is built, the company cannot carry their tracks forward from South Hill, a point which it will reach shortly.

Ottawa, Ont.—The city Board of Control are considering the report of Controller Nelson and Engineer Currie on the new method of block pavement with a view to its use in paving the city's streets.

St. Thomas, Ont.—The city council have decided to construct 6-foot boulevards on Alma Street from Talbot to Redan, leaving a concrete roadway 17 feet wide on each side of the street railway tracks. From Redan Street to the city limits, the roadway will be 26 feet wide. The city will doubtless undertake the work, to be constructed next spring.

▲—**Toronto, Ont.**—Tenders will be received up till October 21st, 1913, for the complete construction of a reinforced concrete bridge between Centre and Olympic Islands. Plans and specifications may be obtained from the Office of Railways and Bridges Section, Department of Works, City Hall, Toronto. H. C. Hocken (Mayor), Chairman, Board of Control.

▲ **Toronto, Ont.**—Tenders will be received up till November 25, 1913, for the supply and erection of structural steelwork for the Gerrard Street bridge over the Don River. Plans and specifications may be obtained from the office of the Railways and Bridges Section, Department of Works, City Hall, Toronto. H. C. Hocken, Mayor.

Toronto, Ont.—Tenders will be received up till November 25th, 1913, for the supply and erection of the steel work for the Gerrard Street bridge. Plans and specifications may be obtained from the Board of Control, City Hall. H. C. Hocken (Mayor), Chairman.

Victoria, B.C.—Mr. H. E. Beasley, General Superintendent of the E. and N. Railway, stated that the steel bridge across French Creek has been completed, and that work on the erection of a steel bridge across the stream is now being undertaken. It is the intention to carry on the track—laying and ballasting as quickly as the material is available from the manufacturers, and weather permitting, to Big Qualicum. From Big Qualicum to Courtenay, being the terminus of the line so far as the present plans are concerned, it will be necessary to span two fairly large waterways—namely, Tsable and Trent rivers. Outside of these, the works consists of track-laying and ballasting, which, with the facilities on the site, should be handled expeditiously. This line will be ready for operation some time in either May or June of next year.

INDUSTRIAL WORKS.

Galt, Ont.—The town council has decided to proceed with the construction of a retaining wall on the west side of the river, to extend back 10 feet, so as to admit of a wider channel and to minimize flood danger.

Hamilton, Ont.—The Hydro Commission have approved the contract made by the city with Mr. Gest for conduit work. Mr. Gest will re-lay the base concrete work of all streets torn up, and the city will replace the 3-inch top dressing.

Ottawa, Ont.—Tenders will be received up till October 23rd, 1913, for dredging required at Glace Bay, N.S. Plans and specifications may be obtained from R. C. Desrochers, Secretary, Department of Public Works, Ottawa, Ont.

Ottawa, Ont.—The preliminary hearing of the application of the Michigan and Lake Superior Power Company, for permission to build a dam at the Soo, and the granting of a preliminary hearing of a similar request to build a dam on the Canadian side by the Algoma Steel Corporation, was the business accomplished by the International Joint Commission at Ottawa, on October 7th. These companies propose to build a dam from each side of the international boundary, which will unit in forming one entire project. Further hearing must be given the scheme in Sault Ste. Marie, where any local objections may be considered.

+—**Saskatoon, Sask.**—The contract for concrete tunnel, to contain the intake pipes at the pumping station, has been awarded to JAMES PRIEL, at a cost of $4,153.

+—**Toronto, Ont.**—Contracts have been awarded by the John Inglis Co., Limited, for the concrete work on their new boiler shop to JOHN E. WEBB AND COMPANY of Toronto, and for the steel work to the PHŒNIX BRIDGE COMPANY of Montreal.

Toronto, Ont.—Tenders will be received up till November 25th, 1913, for the installation of one or more 7½ and 20-million Imperial gallon pumping engines, three water-tube boilers with piping, and coal handling apparatus at the High Level Pumping Station. Plans and specifications may be obtained from Mr. James Milne, Mechanical and Electrical Engineer, Department of Works, City Hall, Toronto. Signed, H. C. Hocken (Mayor), Chairman, Board of Control.

Vancouver, B.C.—The notification that the C.P.R. is prepared to withdraw its opposition to the application of property owners for crown grants for foreshore rights, providing that the owners will undertake not to ask for a level crossing over the company's tracks for each lot, means that extensive developments may now be carried out on the east end waterfront, which will doubtless include the construction of a dock at the end of Renfrew Street.

Victoria, B.C.—Four noted ironfounders—Messrs. H. F. Bullen, Andrew Gray, F. P. Harrison for Evans, Coleman and Evans, and Mr. F. Muirhead, for Jones and Rant, Limited, will offer to construct the rivetted steel pipe in connection with the waterworks project at a lower figure than any yet bid, their purpose being to employ home labor. They offer to purchase the Thetis cove plant from the receiver for the Westholme Lumber Company, to put it into good operating condition, and to retain it on another site when the lease of the land at the cove shall have expired.

Victoria, B.C.—The government has been asked to provide better landing piers at ports on the west coast of Vancouver, touched at by the Canadian Pacific Company's steamer "Princess Maquinna."

Victoria, B.C.—Tenders will be received up till October 20th, 1913, for the delivery of about 555 gross tons of 20 lbs. to-the-yard rails in 20-foot lengths. Plans and specifications may be obtained from W. Galt, Esq., City Purchasing Agent, Victoria, B.C.

Victoria, B.C.—Tenders will be received up till October 20th, 1913, for one hundred 45-foot poles, to be delivered within forty days from date of order. Plans and specifications may be obtained from W. Galt, Esq., City Purchasing Agent. Victoria, B.C.

Winnipeg, Man.—The harbor commissioners of Winnipeg and St. Boniface will ask the Dominion Government for $100,000 to build docks along the Red River. Mr. L. R. Voligny, government engineer, is to make a report on the cost of the work.

Winnipeg, Man.—Tenders will be received up till October 24th, 1913, for the supply and delivery f.o.b., City Yards, of 50 four-inch gate-valves. Plans and specifications may be obtained from the City Engineer, 223 James Avenue, Winnipeg, Man. Signed, M. Peterson, Esq., Secretary, Board of Control.

MISCELLANEOUS.

Calgary, Alta.—Mr. J. H. Brown of the Oil Well Supply Company, Pittsburg, visited the city recently for the purpose of investigating the advisability of establishing in Calgary warehouses from which to supply the local companies now drilling or about to drill in southern Alberta's oilfields.

Chatham, Ont.—An agreement has been officially signed whereby the National Forging Company will take over the plant known as the Defiance Iron Works, and more recently as the Swift Motor Car Company. It will manufacture auto and carriage forgings, and sockets of different kinds, becoming to Canadian trade what the Detroit Socket Company is to American trade.

Edmonton, Alta.—It is announced that Mr. J. D. McArthur will move at once his shops from Transcona to Edmonton, together with all machinery and equipment. His intention is to carry on all work in connection with the Edmonton, Dunvegan and British Columbia Railway at Edmonton.

Fort William, Ont.—The construction of the new building of the Fife Hardware Company, for which the A. C. Stewart Company are the contractors, is being delayed through the exhaustion of the supply of reinforcing steel.

Lachine, P.Q.—Tenders will be received up till October 20th, 1913, for the preparation of a plan of the territory of the said city showing the existing and proposed streets. Plans and specifications may be obtained from Hector Charette, City Clerk.

Medicine Hat, Alta.—Premier Sifton has announced the intention of the government to erect a telephone exchange at Medicine Hat next spring, and that it was expected to complete the building in about three months.

+—Ottawa, Ont.—A contract for the purpose of erecting a station on Main Duck Island has been awarded ALEX. McMASTER of Toronto, at a cost of $17,000.

Sault Ste. Marie, Ont.—The new Drydock and Shipbuilding Company has agreed with the city to place in the city's branch of the Bank of Montreal $25,000 as a guarantee that the construction of its plant will be started not later than next April 1st, and will be ready for operation two years from that date, the sum named not to be released to the company until it has expended $100,000 in constructive work. The contractors for the company's plant are Sir Douglas Fox and Company, a well-known British firm.

St. Catharines, Ont.—The city council has approved of a by-law relating to the establishment in this city of a branch of the firm, Lord and Burnham, which operates factories in Irrington-on-Hudson, N.Y., and in Desplaines, Ill. The firm are manufacturers, designers and erectors of entire complete greenhouses of steel, including boilers and all necessary apparatus in modern greenhouses.

St. Telesphore, Soulanges Co., Que.—Tenders will be received up till October 30th, 1913, for the construction of a steel bridge with concrete pillars across the Beaudette River, in the parish of St. Telesphore, Soulanges Co., Que. Plans and specifications may be obtained from Jos. Ed. Charlebois, Secretary-Treasurer of the municipality.

Toronto, Ont.—The engineers employed upon the work of making tests to determine the character of the different strata at Scarboro', the proposed location for the duplicate waterworks system to be constructed by the city, have completed the work and appear satisfied with the result of their efforts. They will doubtless recommend the construction of a tunnel under the lake off the Scarboro' shore.

Toronto, Ont.—Tenders will be received for sub-contracts on the Methodist Book and Publishing building, cor. John and Queen streets. Plans and specifications may be obtained from John H. Parker and Co., 8 Colborne Street, Toronto.

▲—Toronto, Ont.—Tenders will be received up till November 25th, 1913, for the installation of one or more 7½ and 20 million Imperial gallon pumping engines, three water-tube boilers with piping and coal handling apparatus at the High Level Pumping Station. Plans and specifications may be obtained from the office of Mr. James Milne Mechanical and Electrical Engineer, Department of Works, City Hall, Toronto. H. C. Hocken, Mayor.

Vancouver, B.C.—A statement has been made authoritatively that a new syndicate including Saskatchewan capitalists will be formed for the purpose of developing the coal mines of the northern portion of Graham Island.

Welland, Ont.—It has been stated that steel and other material necessary for the construction of the new high-voltage electric transmission plant being erected by the Hydro-Electric Commission between Welland and Niagara Falls, is arriving on the site. A new transformer house, which will distribute 60,000 h.p., is to be built at a cost of $12,000, with electric equipment at an estimate of $40,000.

CURRENT NEWS.

Calgary, Alta.—The public works department adopted some time ago the policy of reducing all the hills of the city to the lowest possible grade, and in consequence thereof all the streets of the Park Hill district have been graded, and the machines are working now upon the grade in Fourteenth Street West.

Calgary, Alta.—The first of the C.N.R. bridges, that over the C.P.R. tracks near Ogden is practically completed, and work is being started on the other bridges to be erected between it and Calgary. It is expected that all will be finished within 50 days, and with that end in view, contracts are being considered for the temporary depot and buildings to be placed at the east side of the Elbow River. Yards are also to be constructed on that site.

Calgary, Alta.—According to the statement of Mr. R. J. C. Stead, of the publicity branch of the department of natural resources, the C.P.R. are aiming to have a completely double-tracked main line four years from now when the Rogers Pass tunnel will be finished.

Cornwall, Ont.—The Stormont Electric Light and Power Company have completed to all practical purposes the installation of a new lighting system in Cornwall. A distribution of 350 60-candle-power lights has been made in Cornwall, Beaconsfield, Lorneville and Gladstone.

Edmonton, Alta.—At the meeting held between the executive council of the Alberta Government and the board of directors of the Alberta Co-Operative Farmers' Elevator Company, Limited, a statement was presented by the company giving in detail the cost of directing, purchasing and equipping elevators. A total of about $300,000 will be required for the establishment of the 42 elevators which are to be in operation this fall, and 85 per cent. of this will be advanced by the government to be repaid by 20-year annual instalments. With the completion of this year's program of buildings, the company will have in operation in Alberta, during the grain season, 51 elevators.

Lethbridge, Alta.—Two large steel bridges on the G.N.R. between Collins, near Shelby Junction and Great Falls, have been completed. One of these, which span the Teton River is 3,300 feet long and 125 feet high.

London, Ont.—Engineer W. W. Wilson, of the Canadian Stewarts Company, has completed a survey of the proposed line to Port Burwell, which the G.T.R. will use to handle its coal business in the event of the railway electrification by-law being carried.

Montreal, Que.—The raising of the sluice dam of the Western Canada Power Company at Stave River by an additional 10 feet in order to increase the capacity of the plant is practically completed, and the intake dam has also been raised. The company expects to receive the first additional penstock in January, and the second in April of next year, and that by this time also the power house extension will be well under way.

Montreal, Que.—The new drag line scraper, being used by the Cook Construction Company on the aqueduct enlargement contract has proven itself very successful. A number of Montreal contractors have inspected it, and it will be used for excavation at the Welland Canal and other large contracts.

Moose Jaw, Sask.—The city council has succeeded in moving to action the Railway Commission relating to the question of a train service and station facilities from the Grand Trunk Pacific Railway. The Mayor has been notified that the Commission will send an engineer to investigate the city's claims.

St. Catharines, Ont.—On the 30th instant, the ratepayers of St. Catharines will vote upon four by-laws, three of which relate to electric lighting and one to industrial development, at an aggregate expenditure of $116,000.

A Combination in the Interest of Trade

Combinations in business are all right when they make for greater efficiency and better service to the public.

Our business is a combination of many businesses, or special lines, into a great "Departmental House for Mechanical Goods." We find by organizing our business along departmental lines that we can serve industrial Canada more efficiently, more economically and in a way that makes for the best interests of our customers.

You will find it a great convenience to deal with a House that can supply you practically anything you require in the mechanical line all "under one roof" One of the two items mentioned below may interest you

Elwell-Parker Electric Trucks

Wherever used have shown an actual saving of from 25 to 65 per cent., both for railroads and industrial concerns. One large Canadian plant trying electric trucks for the first time claims that each truck, operated by one man, has replaced eight men with eight wheelbarrows.

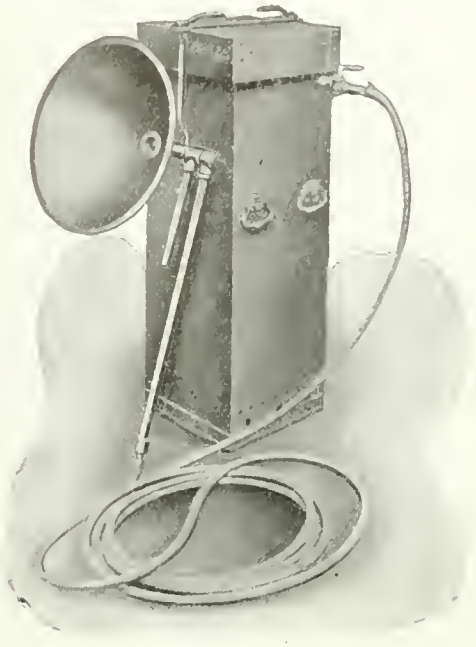
The truck shown above is one of the many types of Elwell-Parker Electric Storage Battery Trucks used by the American Express Co. The Canadian Pacific also use these trucks.

Elwell-Parker Electric Trucks are equipped with Edison Storage Batteries which are now recognized to be about the best on the market. Edison Batteries increase greatly the efficiency of the electric truck. We think so much of them that we would not advise you to purchase any electric truck that was not equipped with Edison Batteries.

Ellwell-Parker Trucks are extremely easy of operation, in no way requiring skilled labor, and by having a spare battery set can be worked continuously without injury.

If you are extending or rebuilding your plant it will pay you to investigate this well known truck.

Ask for Bulletin 107.



The Milburn Light

The No. 3-W Milburn Acetylene Light shown here gives from 5,000 to 12,000 candle power and lights 1,500 feet. The light follows the crane or shovel and throws its rays directly on the work. It lights instantly, requires no attention, and positively defies wind and weather. Has water tight cover and is made to withstand hard usage, the vibration and movement of cranes, steam shovels and dredges. Supplied with 15 inch aluminum reflector and 25 feet of armoured hose with connections. Cost 4 to 6 cents per hour to operate. Over 70,000 Milburn lights have been sold.

Ask for catalogue of Milburn Lights.

TENDERS CALLED FOR

NOTICE TO CONTRACTORS.

Tenders will be received by registered post only, addressed to the Chairman of the Board of Control, City Hall, Toronto, up to noon on **Tuesday, October 21st, 1913,** for the construction of the following sewers:—

Danforth Avenue Storm Overflow Sewer, Section No. 2.

Eastern Avenue, from Leslie Street to Knox Street.

Lane 1st E., Spadina Avenue, from Morris Avenue to Sussex Street.

Lane 1st N., Davenport Road, from Elmwood Avenue to McFarland Avenue.

Victor Avenue, from Carlaw Avenue to 464 feet west.

Lane 1st S., College Street, from Crawford Street to Shaw Street.

Jersey Avenue, from 84 feet 3 ins. S. of Clinton Avenue to 47 feet further south.

Envelopes containing tenders must be plainly marked on the outside as to contents.

Specifications may be seen, and forms of tender obtained at the office of the Commissioner of Works, Toronto.

Tenderers shall submit, with their tender, the names of two sureties (approved of by the City Treasurer, not members of the City Council, or officers of the Corporation of the City of Toronto), or in lieu of said sureties, the bond of a guarantee company approved of as aforesaid.

The usual conditions relating to tendering as prescribed by the City By-law must be strictly complied with.

The lowest or any tender not necessarily accepted.

H. C HOCKEN (Mayor),
Chairman, Board of Control.

Toronto, October 8th, 1913.

TENDERS FOR STEELWORK.

GERRARD STREET BRIDGE.

Tenders will be received by registered post only, addressed to the Chairman of the Board of Control, City Hall, Toronto, Canada, up to noon on **Tuesday, November 25th, 1913,** for the supply and erection of structural steelwork for the Gerrard Street Bridge over the Don River.

Specifications and tender forms may be obtained upon application at the office of the Railways and Bridges Section, Department of Works, City Hall, Toronto.

Envelopes containing tenders must be plainly marked on the outside as to contents.

The usual conditions relating to tendering as prescribed by City By-law must be strictly complied with or the tenders may be declared informal.

Tenderers shall submit with their tenders the names of two personal sureties, approved by the City Treasurer, or in lieu thereof, the bond of a guarantee company approved as aforesaid.

The lowest or any tender not necessarily accepted.

H. C. HOCKEN (Mayor),
Chairman, Board of Control.

City Hall, Toronto, September 22nd, 1913.

TENDERS FOR PUMPING ENGINES, BOILERS AND COAL HANDLING APPARATUS.

Tenders will be received by registered post only, addressed to the Chairman of the Board of Control, City Hall, Toronto, Canada, up to noon on

Tuesday, November 25th, 1913,

for the installation of one or more 7½ and 20 million Imperial gallon Pumping Engines, three Water Tube Boilers, with Piping, and Coal Handling Apparatus at the High Level Pumping Station.

Specifications and tender forms may be obtained upon application at the office of Mr. James Milne, Mechanical and Electrical Engineer, Department of Works, City Hall, Toronto.

Envelopes containing tenders must be plainly marked on the outside as to contents.

The usual conditions relating to tendering as prescribed by City By-law, must be strictly complied with or the tenders may be declared informal.

Tenderers shall submit, with their tenders, the names of two personal sureties approved by the City Treasurer, or in lieu thereof, the bond of a guarantee company approved as aforesaid.

The lowest or any tender not necessarily accepted.

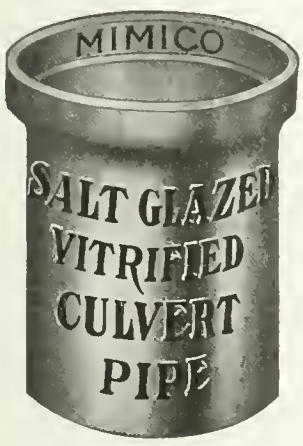
Sewers last indefinitely—or rather they should do so. They will last indefinitely if laid with MIMICO PIPE.



To be permanent a sewer should be built of a good material that can be handled and inspected simply and surely. MIMICO PIPE is finished completely and perfectly at the factory and when delivered can be easily tested. It is far preferable to any material made of several ingredients any one of which may cause failure by being defective, and the mixing of which requires most careful, skilled attention.

Underground Waters for Commercial Purposes.

By Frank L. Rector, B.S., M.D., Bacteriologist, Great Bear Spring Company, New York; Member American Public Health Association, American Microscopical Society, American Chemical Society, American Association for the Advancement of Science, New England Water-works Association. 12mo, vi+97 pages, 8 figures. Cloth $1.00 net.

The subject of underground waters for commercial purposes has received meagre attention at the hands of various authors, and this book is intended to discuss in more or less detail this phase of the question.

Domestic Water-Supplies for the Farm.

By Myron L. Fuller, S.B., Specialist on Underground Water-Supplies. 8vo, x+180 pages, 65 figures. Cloth $1.50 net.

Explains both the advantages and dangers of the common sources of domestic water-supplies, and points out the danger signals and indicates the steps to be taken in order to safeguard the supplies.

SECOND EDITION, Re-written and Enlarged
Engineering for Land Drainage.

A Manual for the Reclamation of Lands Injured by Water.

By Charles Gleason Elliott, Member American Society of Civil Engineers. 12mo, xvi+339 pages, 60 figures. Cloth, $2.00.

Embodies the essential features of drainage engineering in this country at the present time, with the latest developments along each line, and is adapted to the use of the professional engineer and the student.

Farm Gas Engines.

By C. F. Hirshfeld, M.M.E., Professor of Power Engineering, Sibley College, Cornell University, and T. C. Ulbricht, M.M.E., Instructor, Department of Power Engineering, Sibley College, Cornell University. Small 8vo, vii+239 pages, 188 figures. Cloth, $1.50 net.

The greater part of this book has been devoted to a discussion of the weak and strong points in the various designs, to the features which give long and useful life, and those which tend to cause early failures and to the characteristics which best adapt different types to different uses.

TENDERS CALLED FOR

Sealed tenders addressed to the undersigned, and endorsed "Tender for Breakwater at Kincardine, Ont.," will be received at this office until 4 p.m. on Wednesday, October 29, 1913, for the construction of a Breakwater at Kincardine, Bruce County, Ontario.

Plans, specification and form of contract can be seen and forms of tender obtained at this Department and at the offices of H. J. Lamb, Esq., District Engineer, Windsor, Ont.; J. G. Sing, Esq., District Engineer, Confederation Life Building, Toronto, Ont., and on application to the Postmaster at Kincardine, Ont.

Persons tendering are notified that tenders will not be considered unless made on the printed forms supplied, and signed with their actual signatures, stating their occupations and places of residence. In the case of firms, the actual signature, the nature of the occupation, and place of residence of each member of the firm must be given.

Each tender must be accompanied by an accepted cheque on a chartered bank, payable to the order of the Honorable the Minister of Public Works, equal to ten per cent. (10 %) of the amount of the tender, which will be forfeited if the person tendering decline to enter into a contract when called upon to do so, or fail to complete the work contracted for. If the tender be not accepted the cheque will be returned.

The Department does not bind itself to accept the lowest or any tender.

By order,

R. C. DESROCHERS,
Secretary.

Department of Public Works,
Ottawa, September 30, 1913.

Newspapers will not be paid for this advertisement if they insert it without authority from the Department.—46683.

SPECIAL NOTICE TO CONTRACTORS.

RE GREATER WINNIPEG WATER SUPPLY.

(Estimated Cost $13,500,000.)

Notice is hereby given to Contractors that tenders will be invited early in the year 1914 for the construction of works necessary for the delivery of water from Shoal Lake to the Greater Winnipeg Water District. The following is a brief description of the proposed works:—

1. A dyke and channel for the diversion of the Falcon River into Snowshoe Bay.
2. 85 miles concrete aqueduct.
3. 10 miles pipe line (probably 1916 work).
4. 900 lineal feet tunnel under Red River.
5. 85 miles of construction railway.
6. Telephone line.
7. Clearing and ditching.

The fall season of the year affords the best opportunity for inspection of proposed route of the aqueduct, and it is recommended that contractors having a view to tendering on the work should send their inspectors over the line at as early a date as possible.

Particulars as to estimated cost of the work and map of approximate location and profile of aqueduct may be obtained from the undersigned.

M. PETERSON,
Acting Secretary of the
Administration Board,
Greater Winnipeg Water
District.

City Hall,
Winnipeg, Canada,
October 6th, 1913.

Note.—Copy of report of the Consulting Engineers, plan and profile of work and typical details of design may be seen at the office of *The Canadian Engineer*, 62 Church Street, Toronto.

MAIL CONTRACT.

Sealed tenders addressed to the Postmaster-General, will be received at Ottawa until noon on Friday, the 14th November, 1913, for the conveyance of his Majesty's mails, on a proposed contract for four years, six times per week each way, over Mono Road and Rural Mail Route, from the Postmaster-General's pleasure.

Printed notices containing further information as to conditions of proposed contract may be seen and blank forms of tender may be obtained at the Post Office of Mono Road, and at the office of the Post Office Inspector, Toronto.

A. SUTHERLAND,
Post Office Inspector.

Post Office Inspector's Office, Toronto, October 7th, 1913.

52 A.—2,500-26 9-12.

(For further Tenders see page 84.)

CURRENT NEWS.

Moose Jaw, Alta.—For some time there has been a delay on the construction of the C.N.R. bridges crossing the Moose Jaw River. Work has recommenced, and it is expected that the bridge at the second crossing will be completed within a month. Steel can then be laid into South Hill and the temporary station erected. Work on the bridge at the third crossing is to be carried on throughout the winter on the ice so that the erecting of the station in Block 48, Old City, may be begun in the spring.

Ottawa, Ont.—It is planned that the Government system of wireless telegraphy between Le Pas and Port Nelson will be in operation before Christmas. The apparatus, which will have two of the longest ranges in Canada, is designed to enable the department to keep in touch with the Hudson Bay Railway work.

Ottawa, Ont.—A new line of street railway has been finished and officially opened in the city running over Bank Street Bridge to Ottawa South.

Regina, Sask.—The street railway running through Broad Street subway has been completed, and an initial trip over the line has been made by representative citizens.

Sarnia, Ont.—Work has been commenced on what will be in Sarnia the industry second only in importance to the Imperial Oil Company. The new industry is the Perfection Stove Company, which is an adjunct to the Standard Oil Company, manufactures oil stoves and all kinds of oil-burning appliances.

Saskatoon, Sask.—The work upon the new Dominion Government Interior Elevator at Saskatoon has been set in operation. The contract which was awarded recently to John Davies, Esq., a local contractor, calls for the removal of 60,000 yards of material, a much larger contract than anything similar undertaken previously in the city.

Saskatoon, Sask.—The C.N.R. has commenced construction of a spur line into Factoria, a sub-division about three miles north of the city.

St. John, N.B.—Two-thirds of the work on the three miles of sewer extension in Beaconsfield is now complete, and the entire work will be finished by the first of November, at a cost of about $30,000.

Victoria, B.C.—Construction is soon to be commenced on the new wharf to be built by the Dominion Government at Nootka Harbor, according to the announcement of Mr. C. A. Pringle, secretary of the Nootka branch of the Vancouver Island Development League. A further appeal is to be submitted by the league to the provincial government for a grant to improve the roads that radiate from the new wharf.

Refined to Definite Standards

BITUMEN 99%

MEXICAN EAGLE ASPHALT

TRADE MARK

Every Barrel Guaranteed Uniform

BITUMEN 99%

Mexican Eagle Paving Asphalt is specially adapted to the Canadian climate. It is not susceptible to changes in temperature. It will not mark in the hottest weather, nor is snow or ice likely to crack it. Dow and Smith, Chemical Engineers, say: "This is a very high quality of asphalt."

ANALYSIS

By DOW & SMITH, Chemical Engineers

"Bitumen soluble in Carbon Disulphide - - - 99%
"Bitumen soluble in Carbon Tetrachloride - - 99%
"Bitumen soluble in Penna naphtha boiling between 40° and 60° C. - - - - - - - 78%
"Penetration at 77° F. - - - - - - - 44
"Ductility unfluxed - - - - - - - 22 cms.
"Penetration of Asphaltic Cement at 77° F. - - 50
"Ductility of Asphaltic Cement at 77° F. - - 45 cms.
"Remarks. This is a very high quality of refined Asphalt and is suitable in every respect for paving purposes."

Every barrel of our asphalt is guaranteed to be uniform and according to analysis. This is the guarantee of our principals, the Mexican Eagle Oil Co. Limited, a Company that has over twenty-five million dollars working capital.

Mexican Eagle Paving Asphalt is superior in purity to Burmudez, Trinidad, Californian or any other asphalt on the market. It is a favorite also for its high cementing value and ductility.

We can also supply different grades of Mexican Eagle Asphalt for asphalt fillers, road binders, roofing asphalts, wooden water pipe coatings, waterproofings, etc. Also Durazzo Sicilian Rock Mastic Asphalt for sidewalks.

For prices, samples and full particulars, please address

TRANSPORTATION BUILDING — MONTREAL

Illustration below shows a portion of our Mexican plant in the Isthmus of Tehuantepec. Every structure in sight belongs to the plant, but a large portion to the left is unseen. The capacity was recently increased by over fifty per cent. We can get 75,000 tons of the world's very best paving asphalt from this plant in 1914 if the Canadian cities and towns require that quantity.

SECOND-HAND MACHINERY

Contractors' Machinery For Sale Or Rent

We have in stock the following second-hand equipment for immediate delivery.

Get further details and prices.

1—6½" x 8" double cylinder, double drum steam hoist.
1—No. 3 Ransome concrete mixer.
5—6-ft. Ransome concrete carts.
13—5-ft. Sterling concrete carts.
1—8"x 10"x 8" steam driven air compressor.
1—6" x 5" x 7" steam driven air compressor.
1—6" belt driven centrifugal pump.
1—5" belt driven centrifugal pump.
1—15 H.P. semiportable boiler on skids.
1—14 H.P. vertical boiler on wheels.

H. W. PETRIE, LIMITED
Front St. W., TORONTO, Ont.

PANAMA CANAL EQUIPMENT FOR SALE.—The Isthmian Canal Commission will offer for sale in the near future the equipment used in building the Panama Canal, such as rolling stock, excavating machinery, floating equipment, miscellaneous plants, and miscellaneous equipment, including locomotives, cars, steam shovels, cranes, unloaders, earth spreaders, track shifters, rock drills, well drills, dredges, barges, tugs, launches, pile drivers, concrete handling plants, pumps, rock crushers, etc. Inquiries from users of such equipment are invited for its purchase. Catalogues listing the equipment offered for sale and other information may be obtained upon application to the General Purchasing Officer, Isthmian Canal Commission, Washington, D.C. F. C. Boggs, Major, Corps of Engineers, U.S.A., General Purchasing Officer.

FOR SALE.—One model 41 Marion steam shovel, less than a year old; one Porter locomotive; ten 4-yard Western cars; one 40 H.P. boiler. Please address Box 154, *The Canadian Engineer*, Toronto.

TRADE ENQUIRIES.

The following inquiries relating to Canadian trade have been received:—1084.—A large importing firm in Brussels, Belgium, wishes to enter into communication with exporters of pulpwood for Canada, with a view to opening up a direct trade between the two countries. 1088.—A firm in Frankfurt, is desirous of obtaining the representation of first-class Canadian firms for Germany, and possibly Europe. The names of the firms making these inquiries, with their addresses, can be obtained upon application to:—"The Inquiries Branch, the Department of Trade and Commerce, Ottawa," or the Secretary of the Canadian Manufacturers' Association, Toronto, or the Secretary of the Board of Trade at London, Toronto, Brandon, Halifax, Montreal, St. John, Sherbrooke, Vancouver, Victoria, Winnipeg, Calgary and Chambre de Commerce du District du Montreal.

MONTREAL MARKET LETTER

Montreal, October 14th.

Local iron and steel interests are all keenly on the alert to the effect of the new tariff measures in the United States. An interview given out during the week by Mr. J. R. Wilson, a director of the Dominion Steel Corporation, indicated the possibility, if not the probability, that the lowering of the tariff by the United States might result disastrously to the iron and steel companies in Canada, through the increased competition from American manufacturers which might arise therefrom. He naturally urged protection for the Canadian iron and steel concerns as a remedy for the unfavorable situation which might arise. On the other hand he was hopeful that the effect of the alteration in the coal duty would be advantageous to the Canadian coal companies.

Not even have the financial and industrial circles of the United States determined what will be the effect upon the steel industry of that country. In a general way prices of iron and steel products have declined considerably during the past few days, this decline being generally thought to have resulted from the lowering of the tariff. However, there are those who declare that this decline would have taken place anyway. Meantime, all is mere conjecture, and this being the case, it is not surprising that the iron and steel trade of Canada should be simply occupying a waiting position. The explanation for the falling off in orders on the other side of the border is now offered, that it is not so much a question of price with the purchaser as with the finding of the price. The claim is made that most of the railways are desperately hard up and are unable to place their orders in the way that they would wish, hence they are delaying until the last moment. In Canada it was clearly indicated by Sir Thomas Shaughnessy at the recent annual meeting that construction would show considerable falling off from this forward in the case of the C.P.R., and doubtless this will more or less apply to the other railways, the new transcontinental lines being now nearly completed. The point which is causing some discussion now is as to whether the orders for rolling stock will show a falling off. The Canadian Car and Foundry Company has apparently orders on hand for the next three months. Meantime the new works at Fort William are rapidly being completed and the Eastern car works are ready for operation, so that the capacity of the car companies has considerably increased. Prices are generally the same as a week ago.

NEW INCORPORATIONS.

St. Johns, Que.—The Canadian Clarendon Marble Co., Limited, $100,000. H. J. Trihey, W. P. Kerney, E. Lafontaine.

Windsor, Ont.—Windsor Sand and Gravel Co., Limited, $40,000. H. A. White, M. White, S. E. McDowell.

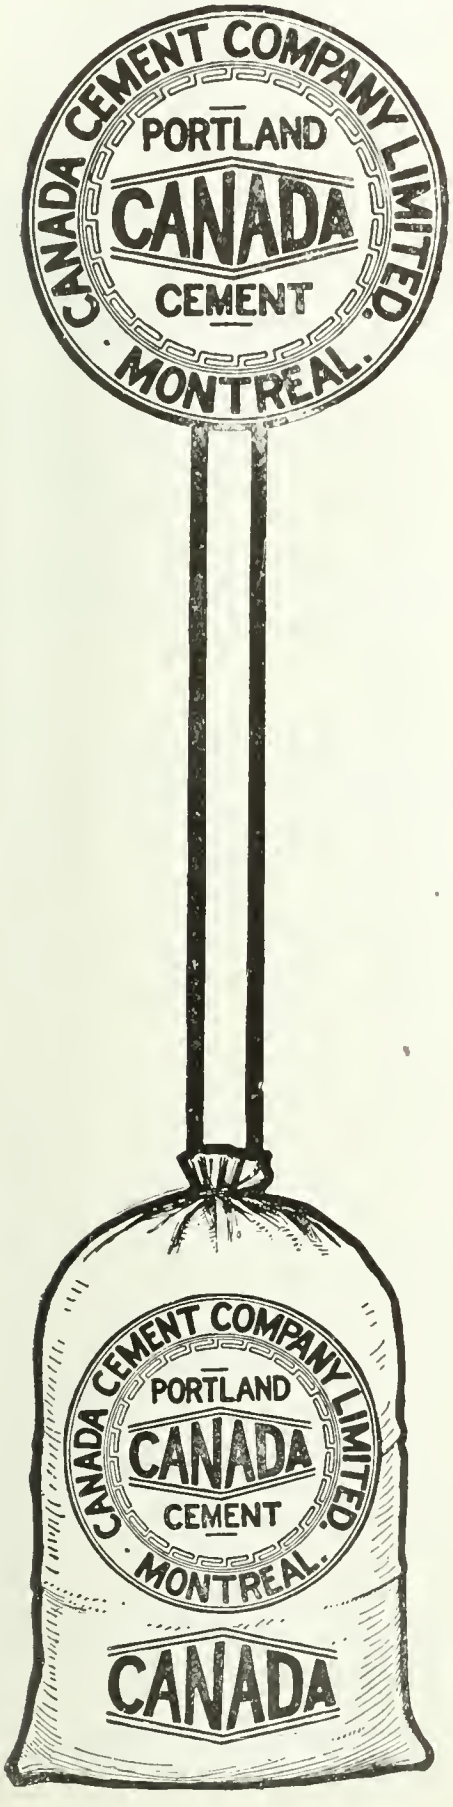
PERMANENCE—



an ideal that is now attainable

THE superiority of concrete over all other materials for the building of permanent structures is now generally admitted.

The next step towards ideal construction, is to realize that for satisfactory concrete work, it is necessary to use a cement that is uniformly high-grade

CANADA Portland CEMENT

is the selection of the leading engineers, architects and contractors. Their experience has proved that in this brand they can obtain a certainty of success.

With concrete coming into more and more general use for the construction of buildings, bridges, viaducts and highways, it is vitally important that those in authority on such matters should select the best materials obtainable.

Use the cement that our best architects and engineers have selected for their most important undertakings. Select Canada Cement — it costs no more than any others.

FOUNDRY AND SHOP WANTED.—United States manufacturer desires to lease Canadian foundry and machine shop. Please give full particulars of equipment and state terms desired. All letters confidential. Address Box 156, *The Canadian Engineer*, Toronto.

CURRENT NEWS.

St. John, N.B.—The new water main to the plant of the Atlantic Sugar Refineries, now being constructed on the Ballast wharf, has been completed. The pipe has been laid for a distance of 9,200 feet at a cost of $32,000.

Summerland, B.C.—The big steel girder bridge spanning Trout Creek canyon will be completed by the end of the month, and almost as soon the first locomotive will enter Summerland. The road-bed is ready for a distance of 40 or 50 miles from the bridge for ties and steel, and these will be laid as rapidly as possible when locomotives can pass over the bridge. The only remaining section of railroad to be constructed in the Okanagan, is the three mile line of Kettle Valley Railway east of Penticton, and on this work has already been commenced.

Toronto, Ont.—Vice-president David McNicoll, of the Canadian Pacific Railway and Chief Engineer H. R. Safford of the Grand Trunk system, in company with the General Superintendents of the Ontario divisions of these railways, have inspected the Toronto terminals and have examined the site for the new station. They stated that plans for the new structure agreeable to both companies are completed, and that actual construction work will be commenced as soon as the Dominion Railway Commission gives its final ruling in connection with the dispute concerning the grades.

Toronto, Ont.—The Hon. J. J. Foy has stated that, should the Edison Electric Company of Detroit, make any effort to cross the Detroit River, as is anticipated, steps will be taken to restrain it, and to conserve the rights of Ontario. If the Dominion Government should grant to the Michigan company the privilege of carrying its cables over to Essex, the provincial government can prevent this being done over the water lots which are its recognized property.

Vancouver, B.C.—In August of this year the provincial government commenced the work of stringing telephone wires in the lower coast fire districts. Fifty-five miles of wire have already been used, but further communication to a point 60 miles north of Harriette Bay will be opened up this year. It will be possible to have these provincial lines subsequently incorporated in the Dominion Government's system.

Vancouver, B.C.—The C.N.R. Company is awaiting plans for its entrance into False Creek, which will settle the difficulty of the crossing of the G.N.R. tracks. Until a plan is adopted, nothing can be done concerning the railway company's entrance into Vancouver.

Windsor, Ont.—The Grand Trunk Railway Company have equipped with smoke consumers all the yard locomotives at Windsor as well as at different points on its system. Road locomotives may also be equipped in this way, though the advantages accruing are greater in the case of yard locomotives.

Winnipeg, Man.—To further the sale of power, the city of Winnipeg has decided to offer a commission of 40 per cent. to all citizens who secure a new customer.

MARKET CONDITIONS

Montreal, October 11th, 1913.

Bar Iron and Steel—Trade is reported active. Bar iron, $2.10 per 100 pounds; best refined horseshoe, $2.35; forged iron, $2.25; mild steel, $2.20; sleigh shoe steel, $2.20 for 1 x ⅜ base; tire steel, $2.30 for 1 x ⅜ base; toe caulk steel $3; machine steel, iron finish, $2.25.

Cement—Canadian cement is quotable, as follows, in car lots, f.o.b., Montreal:—$1.35 to $1 40 per 350-lb. bbl., in cotton bags, adding 10c. for each bag. Good bags re purchased at 10c. each. Paper bags cost 2½ cents extra, or 10c. per bbl. weight.

Chain—The market is quoted per 100 lbs. as follows:—¼-in., $5.65; 5/16-in. $4.70; ⅜-in., $4.00; 7/16-in., $3.65; ½-in., $3.45; 9/16-in., $3 45; ⅝-in., $3.35; ¾-in., $3.25; ⅞-in., $3 15; 1 in., $3.05.

Explosives and Accessories—Dynamite, 50-lb. cases, 40 per cent. proof, 15c. in single case lots Montreal; 50 per cent., 16½c., and 60 per cent., 18c. Blasting powder, 25-lb. kegs, A, $1.85, and B, $2.35 per keg. Special quotations on large lots of dynamite and powder. Detonator caps, case lots, containing 5,000, 75c. per 100; double strength, $1, and broken lots higher; electric blasting apparatus:—Batteries, 1 to 10 holes, $13.50; 1 to 10 holes, $20.50; 1 to 50 holes, $41. Wire, leading, 1c. per foot; connecting, 50c. per lb. Fuses, platinum, single strength, per 100 fuses:—4-ft. wires, $3 double strength, $3.50; 6-ft. wires, $3.54, and double, $4.04; 8-ft. wires, $4.08, and double, $4.58; 10-ft. wires, $5, and double, $5.12.

Galvanized Iron—The market is steady. Prices, basis, 28-gauge, are:—Queen's Head, $4.40; Colborne Crown, $4.20; Apollo, 10¾ oz., $4 30. Add 25c. per 100 lbs. to above figures for less than case lots; 26-gauge is 25c. less than 28-gauge. American 28-gauge and English 26 are equivalents, as are American 10¾ oz., and English 28-gauge.

Galvanized Pipe—(See Pipe, Wrought and Galvanized)

Iron.—Following prices are on dock. No. 1 Summerlee, $22.50 per ton; selected Summerlee, $22; soft Summerlee, $21.50 per ton. No. 3 Middlesboro irons are about $19 per ton. Carron iron number for number and grade for grade is quoted about the same price as Summerlee. Canadian iron sells here at about $19.25 to $19.50 per ton, on track.

Lath—See Lumber, etc.

Lumber, etc.—Prices on lumber are for car lots, to contractors, at mill points. Red pine mill culls out, $20 to $22 per 1,000 feet; white pine, mill culls, $20. Spruce, 1-in. by 4-in. to 6-in., $21; 1 x 7 to 9, $24 per 1,000 ft.; mill culls, $18. Hemlock log run, culls out, $19. Railway Ties, Standard Railway Ties, hemlock or cedar, 50 to 55c. each. Telegraph poles: seven-inch top, cedar poles, 25-ft. poles, $2, each; 30 ft., $3.75; 35-ft., $4.50 each; 40-ft., $6; 45 to 50, 16c. per foot. Laths: Quotations per 1,000 laths, at manufacturers' points. Spruce 4-ft. x 1½ in., mill run, $3 to $3.25; pine, 4-ft. x 1⅜-in., mill run, $3.25 to $3.75. Shingles: Cedar shingles, same conditions as laths, X, $2 10; XX, $2.40; XXX, $2.80.

Pipe—Cast Iron—The market is dull and rather easy:—$34 for 6 and 8-inch pipe and larger; $35 for 40-inch at the foundry. Pipe, specials, $3 per 100 pounds. Gas pipe is quoted at about $1 more than the above.

Pipe—Wrought and Galvanized—Demand is fair and the market steady: —¼-inch $5 50, with 63 per cent. off for black, and 48 per cent. off for galvanized; ⅜-inch, $5.50, with 63 per cent. off for black, and 48 per cent. off for galvanized; ½-inch, $8 50, with 69 per cent off for black, and 59 per cent. off for galvanized. The discount on the following is 72½ per cent. off for black, and 62½ per cent. off for galvanized: ¾-inch, $11.50; 1-inch, $16.50; 1¼-inch, $22.50; 1½-inch, $27. On the following the discount is 72½ per cent. for black and 62½ per cent. for galvanized: 2-inch, $36; 2½-inch, $57.50, and 3-inch $75.50; 72½ per cent. off for black, and 62½ per cent. off for galvanized: 3½-inch $95 4-inch, $1.08.

Toronto, October 15th, 1913.

The following are the wholesale prices for Toronto, where not otherwise explained, although for broken quantities higher prices are quoted:

Axes.—Standard makes, double bitted, $6 to $10; single bitted, per dozen, $7.50 to $9.

Bar Iron—$2.25 base, per 100 lbs., from stock to wholesale dealer. In enormous demand.

Bar Mild Steel—Per 100 lbs., 52.25. Sleigh shoe and other take same relative advance.

Boiler Plates—½-inch and heavier, $2.20. Boiler heads 25c. per 100 pounds advance on plate. Tank plate, 3-16-inch, $2.40 per 100 pounds.

Boiler Tubes—Orders continue active. Lap-welded, steel, 1¼-inch, 10c.; 1½-inch, 9c. per 10-ft.; 2-inch $8.50 to $9; 2¼-inch, $10; 2½-inch, $10.50; 3-inch, $12.10; 3½-inch, $15; 4-inch, $19.

Bricks—In active movement. The price is $11.50 for grey stock, $12 for red stock. Don Valley pressed brick are in request. No. 1 dry pressed and buff bricks are worth $18 delivered and $17 at works per 1,000. Port Credit Brick Company's prices are as follows, f.o.b., Port Credit: Wire cut bricks, $10 per M.; pressed bricks, $14 to $15 per M., three grades.

Broken Stone—Lime stone, good hard, for roadways or concrete, f.o.b., quarries 70 to 75c per ton of 2,000 lbs., either 1-inch, 10c., 2-inch or larger, price all the same. Rubble stone, 55c. per ton, Schaw station, and a good deal moving. Broken granite is selling at $3 per ton for good Oshawa, or Quebec Province. At Washago, $2.50 per ton for small, and $1.15 for large, freight to Toronto 60 cents.

Cement—Demand very brisk, and prices maintained. In large quantities the price is $1.50, sacks, 40c. extra; car lots $1.55, sacks extra; city dealers ask $1.85, sacks extra. Prices remain firm.

Copper Ingot—The market is lower at 15½ to 16c., sheet copper case (16 oz. soft), 22½c. to 24½c. per lb.

Detonator Caps—75c. and $1 per 100; case lots, 5,000, 20 per cent. off.

Dynamite—The prices for this explosive vary according to the percentage of nitro-glycerine compounded in the mixture and are as follows, f.o.b., Toronto: 40 per cent., 16¼ cents per pound, 1 to 9-case lots, 50 lbs. to case. For each additional 10 per cent. nitro-glycerine add 1½c. per hundred. For 10-case lots and over deduct ½ cent. For 20-case lots and over deduct 1 cent. For 40-case lots and over deduct 1½ cents.

Fuses—Electric Blasting—Double strength, $3.50 per hundred, advance 54c. per hundred for each 2-in. wire additional. Single strength, $3 per hundred, advance 54c. per hundred for each 2-in. wire additional.

Iron Chain—¼-inch, $5.75; 5-16-inch, $5.15; ¾-inch, $4.15; 7-16-inch, $3.95; ½-inch, $3.75; 9-16-inch, $3.70; 5-8-inch, $3 55; ¾-inch, $3.45; ⅞-inch, $3.40; 1-inch, $3.40 per 100 lbs.

Iron Pipe—Quotations are changed as follows:—Black pipe, ¼-inch, $2.04; ⅜-inch, $2.04; ½-inch, $2.72; ¾-inch, $3.16; 1-inch, $4.54; 1¼-inch, $6.19; 1½-inch, $7.43; 2 inch, $9.90; 2½-inch, $15.80; 3-inch, $20.75; 3½-inch, $26.13; 4-inch, $29.70; 5-inch, $40 60; 6-inch, $52.64. Galvanized Pipe, ¼-inch, $2.86; ⅜-inch, $2.86; ½-inch, $3.57; ¾-inch, $4.31; 1-inch, $6.19; 1¼-inch, $8.44; 1½-inch, $10.13; 2-inch, $13.50; 2½-inch, $21.56; 3-inch, $28.31.

Lead—Firmer, $5.25 to $5.50.

Pig Iron—We quote Clarence at $24 for No. 3; Cleveland, $24; Summerlee, $27; Hamilton quotes $22; Midland, No. 1, $22; No. 2, $21.50. There is considerable enquiry for 1912.

Pitch and Tar—Pitch, unchanged at 75c. per 100 lbs. Coal tar, $3.75 per barrel.

Roofing Slate—Most of the slate used in Canada comes from Pennsylvania or Maine, the Canadian supply being slender and mostly from the Rockland quarries of the Eastern Townships, in Quebec. There is a great variety of sizes and qualities, so that it is difficult to indicate prices But Jackson Bangor, 10 x 16 may be quoted at $6.75 per square of 100 square feet f.o.b. cars, Toronto; seconds, 50c. less. Mottled, $8; green $8, with a prospect of advance. Dealers are fairly busy.

Sand—Sharp, for cement or brick work, $1.15 per net yard f.o.b., cars, Toronto siding.

Sewer Pipe—

	4-in.	6-in.	9-in.	12-in.	24-in.
Straight pipe; per foot	$0 25	$0.40	$0.65	$1.00	$ 3.25
Single junction, 1 or 2 ft. long	1.00	1.60	2.60	4.00	13.00
Double junctions	1.25	2.00	3.25	5 00	16.25
Increasers and reducers	...	1.60	2.60	4.00	13.00
P. & H. H. traps	2.00	3.20	6.50	15.00	....
Bends	0.75	1.20	1.95	3.00	9.75

Above is the October list as changed. The retail price is less 65 per cent. off these figures on all sizes 9 inches and under, or less 60 per cent. off these figures on anything over 9 inches. For car-loads a greater discount.

Steel Beams and Channels—Active—We quote:—$2.65 to $3 cut to length per 100 lbs., according to size and quantity; angles, 1½ by 3-16 and larger, $2.50 to $2.75; tees, $2 75 to $3 per 100 lbs. Extra for smaller sizes of angles and tees.

Sheet Copper—22c. per lb.

Sheet Steel—American Bessemer, 10-gauge, $2.75; 12-gauge, $2.80; 14-gauge, $2.50; 17, 18, and 20-gauge, $2.75; 22 and 24-gauge, $2.80; 26-gauge, $2.85; 28-gauge, $3. A very active movement is reported at unchanged prices.

Sheets, Galvanized—Apollo Brand—Sheets, 6 or 8 feet long, 30 or 36 inches wide: 10-gauge, $3; 12-14-gauge, $3; 16, 18, 20, $3.30; 22-24, $3.40; 26, $3.50; 28, $3.90; 29, $4.10; 10¾, $4.10 per 100 lbs. Fleur de Lis—28-gauge, $4.25; 26, $4.05 per 100 lbs. Active and firm at these prices.

Tin—The combination seems to hold, and the price, 45 to 50c., lower.

Tool Steel—Jowett's special pink label, 10½c. Cammel-Laird, 16c 'H.R.D." high speed tool steel, 65c.

Tank Plates—3-16 inch, $2.40 per 100 lbs.

Zinc—Spelter—Good demand, and the feeling strong. Light stock; excellent demand. We quote very firm at $6 to $6.50 per cwt.

Winnipeg, October 14th, 1913.

Anvils—Per pound, 11½ to 12½c.; Buckworth anvils, 80 lbs. and up, 10¼ to 10¾c., anvil and vise combined, each $5.50.

Bar Iron—$2.50 base.

Bars—Crow, $4.50 per 100 pounds.

Beams and Channels—$3 to $3.10 per 100 up to 15-inch, 4, 30, 41, 50, 118, 119, 172, 132, 145, 176.

Brick—Kiln run per M, $13; sewer pipe per M, $14; chimney per M, $14; veneer per M, $15; pressed per M, $25 to $50; enameled per M, $100; sand lime per M, $13.

Cement, Portland—$2.40 to $2.50 per barrel.

Chain—Coil, 3-16-in., $10; ¼, $7.25; 5-16, $5.85; ⅜, $5; 7-16, $4.75; ½, $4.50; 9-16, $4.50; ⅝, $4.40; ¾, $4.25. Logging, 5-16, 6½c.; ⅜, 5¾c. Tie out, 70 and 10 per cent.

Copper—Tinned, boiler, 26½c., planished, 29½c.; boiler and T. K. pits, plain, tinned, 45 per cent. discount.

Dynamite—$11 to $13 per case.

Galvanized Iron—Apollo, 10¾, $4.80; 28, $4.60; 26, $4.20; 22, $4.10; 24, $4.10; 20 $4; 18 $3.95; 16, $3.90. Queen's Head, 28, $4.90; 26, $4.70; 24, $4.30; 22, $4.30; 20, $4.10 per cwt.

Iron—Swedish iron, 100 lbs., $4.75 base; sheet, black, 14 to 22 gauge, $3.75; 24-gauge, $3.90; 26-gauge, $4; 28-gauge, $4.10. Galvanized—American 18 to 20-gauge, $4.40; 22 to 24-gauge, $4.65; 26 gauge, $4.65; 28-gauge, $4.90; 30-gauge, $5.15 per 100 lbs. Queen's Head, 22 to 24-gauge, $4.65; 26-gauge English, or 30-gauge American, $4.90; 30-gauge American $5.15; Fleur de Lis, 22 to 24-gauge, $4.50; 28-gauge American, $4.75; 30-gauge American, $5; bar, $2.50 base.

Pipe—Iron, black, per 100 feet, ¼-inch, $2.40; ⅜-inch, $2.55; ½-inch, $3.35; ¾-inch, $4; 1-inch, $5.75; 1¼-inch, $7 80; 1½-inch, $9.35, 2-inch, $12.50; galvanized—½-inch $4.35; ¾-inch, $5.20; 1-inch, $7.55; 1¼-inch, $10.25; 1½-inch, $12.25; 2-inch, $16.40. Lead, 7.60 per cent., full coil.

Pitch—Pine, $6.50 per barrel, in less than barrel lots, 4c. per lb.; roofing pitch, $1 per cwt.

Steel Plates, Rolled—3-16-in. $3.35 base; machinery, $3 base; share, $4 50 base; share crucible, $5.50; cast share steel, $7.50; toe caulk, $4.50 base tire steel, $3 base; cast tool steel, lb., 9 to 12½c.

Tool Steel—8½ to 15c. per pound.

THE WINNIPEG-SHOAL LAKE AQUEDUCT

THE 95-MILE WATER SUPPLY LINE FOR THE GREATER WINNIPEG WATER DISTRICT—ENGINEERING FEATURES OF THE PROPOSED ROUTE AND THE DESIGN THROUGHOUT

THE Administration Board of the Greater Winnipeg Water District has not been tardy in getting down to action in the matter of the proposed supply of water from Shoal Lake for Winnipeg. *The Canadian Engineer*, in September 11th issue, published the salient points of the report of Messrs. Hering, Stearns and Fuertes, the board of consulting engineers instructed on May 20th, 1913, to submit a report on the best means of supplying water from this source, together with an estimate of the cost and general plan of the development.

This project has been the acme of interest for some little time as the most desirable source of supply for the city, although distance 95 miles, and great enthusiasm was evinced when the report, mentioned above, pronounced the proposal quite within the latitude of prudence, and, in fact, a very advantageous one for the city. On October 1st the rate-payers strongly endorsed a by-law authorizing, for the supply from this source of 85,000,000 gallons per twenty-four hours, the expenditure of $13,045,600, as estimated in the report. In the issue of October 16th, this journal announced the appointment of Mr. Jas. H. Fuertes as consulting engineer, and Mr. W. G. Chace, as chief engineer, also the formation of a board of commissioners with Mr. R. H. Reynolds as the first appointed commissioner, with others to follow at an early date. The same issue published a special announcement to contractors relative to tenders for the proposed work, and at the present time the ground is being examined along the proposed route, the contractors taking advantage of the season's remaining permissible weather. A study of Fig. 1 will familiarize the reader with the magnitude of the scheme.

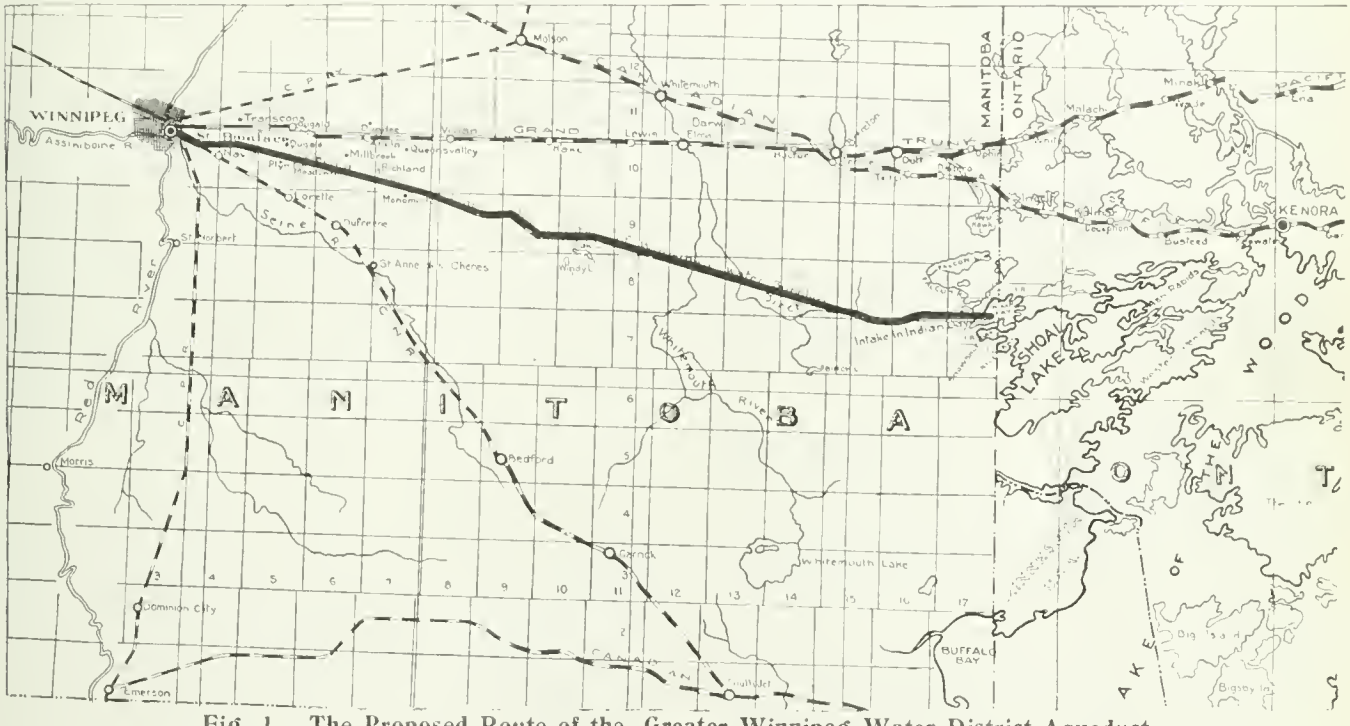

Fig. 1.—The Proposed Route of the Greater Winnipeg Water District Aqueduct.

The main engineering features of the work for immediate construction constitute:—

1. A dyke and channel for the diversion of the Falcon River into Snowshoe Bay.

2. A concrete masonry aqueduct, having a continuous down grade for 84.73 miles from an intake at Indian Bay to a point about one mile east of Transcona, the aqueduct to have a capacity of 85,000,000 gallons of water daily.

3. A pipe 5 feet in diameter, extending from the end of the masonry of the concrete aqueduct, most of the way through streets to Victoria Park on the west side of the Red River in Winnipeg, this pipe to be of steel except under the Red River, where cast-iron pipe laid in a tunnel is recommended.

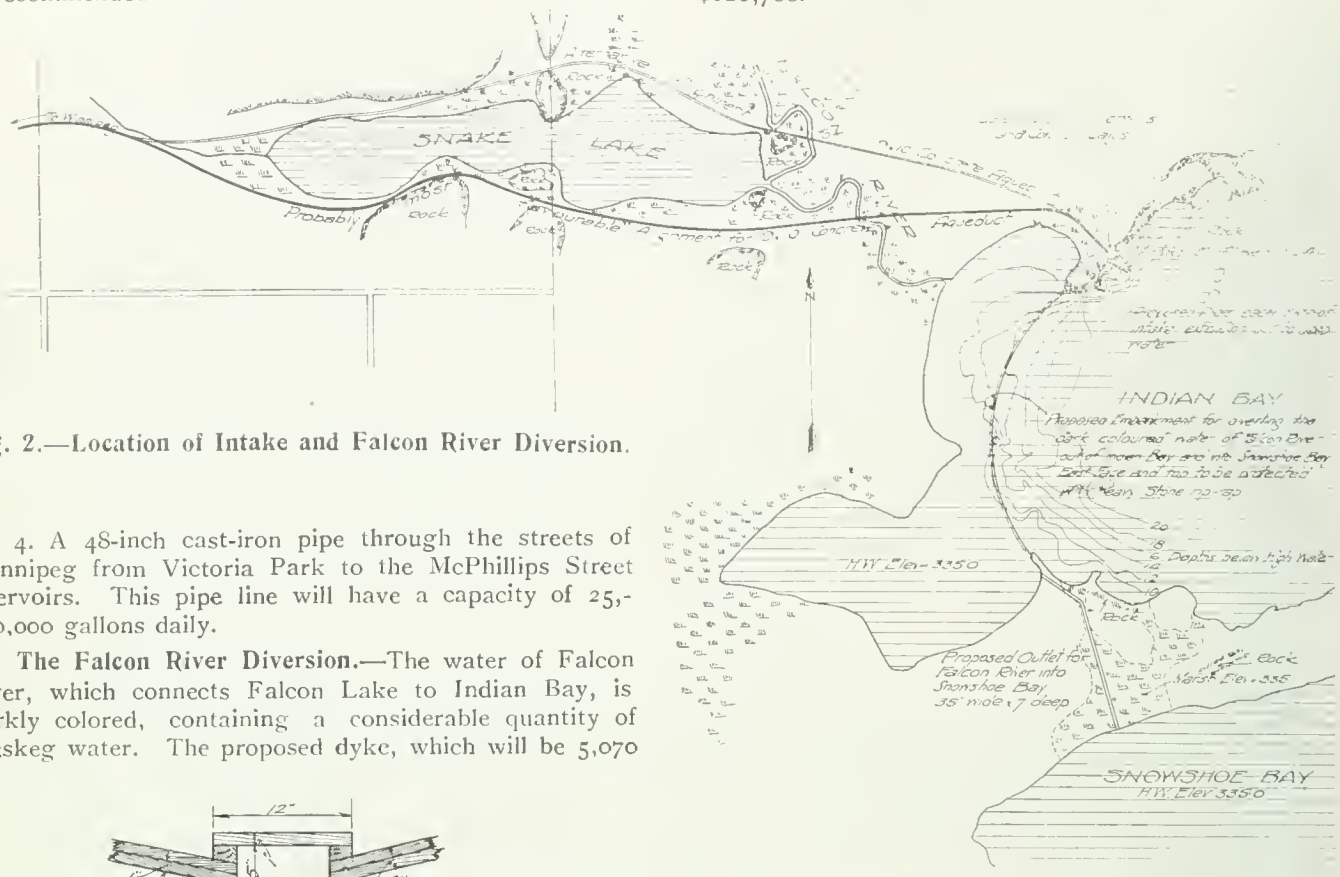

Fig. 2.—Location of Intake and Falcon River Diversion.

4. A 48-inch cast-iron pipe through the streets of Winnipeg from Victoria Park to the McPhillips Street reservoirs. This pipe line will have a capacity of 25,000,000 gallons daily.

The Falcon River Diversion.—The water of Falcon River, which connects Falcon Lake to Indian Bay, is darkly colored, containing a considerable quantity of muskeg water. The proposed dyke, which will be 5,070

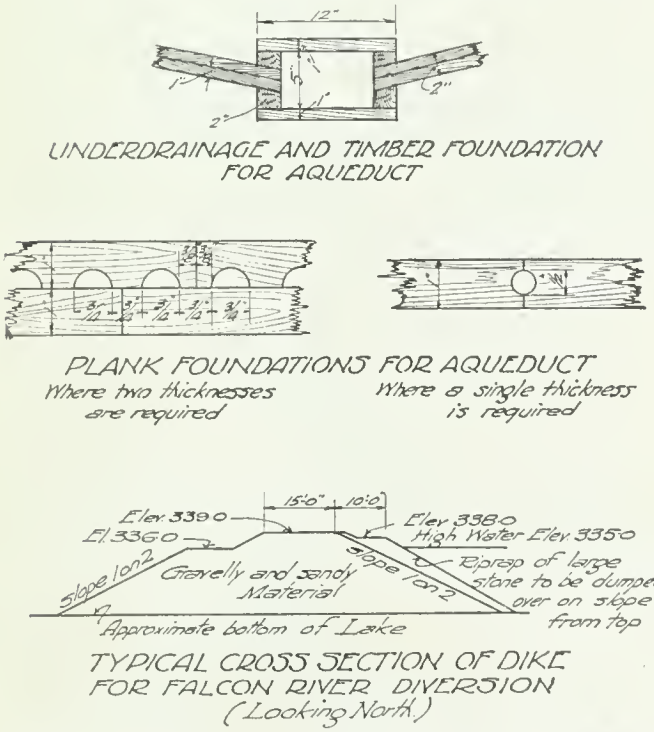

Fig. 3.—Details of Aqueduct Foundation, and Section of Falcon River Embankment.

feet in length, is to divert this water southward to a proposed channel, 3,300 feet long, 35 feet wide and 7 feet deep, which will form an outlet through a shoulder of marshy land only a few feet above the water level, into Snowshoe Bay, where there will be no liability of this discolored water becoming associated with the water surrounding the intake in Indian Bay. Fig. 2 illustrates this diversion, and Fig. 3 gives a typical cross-section of the proposed embankment. The report estimates the Falcon River diversion to cost in the neighborhood of $120,700.

The Concrete Aqueduct.—The concrete aqueduct, to be 447,330 feet in length, extending from Shoal Lake to the site of a proposed reservoir, one mile east of Transcona, is shown in profile in Fig. 4, and various cross-sections are given in Fig. 5. The location of its intake, as denoted in Fig. 2, is at the northwesterly corner of Indian Bay, where the shore is of a rocky nature, and where the water is of moderately receding depth. The intake will be provided with control gates and screen chamber on shore, and will be protected from any material which may drift along the shore, by piers, on either side, extending out 150 feet into deep water. The experts' report suggests, as an alternative to these piers, the laying of a large submerged conduit to bring the water from a point, distant about 150 feet from shore. The gate and screen chamber will be of liberal area to necessitate as little fall as practicable of the water from the bay to the aqueduct. Details of the design are not in hand, except that the report recommends the use of at least two sluice gates, not less than 5 feet wide and 6 feet high, and screens with a total length of not less than 50 feet, and a height extending from the top of the aqueduct to the surface of the water.

With respect to the advisability of using concrete masonry in the construction of the aqueduct, apprehending the disintegrating effect of the presence of sulphates and sulphuretted hydrogen in certain soils, they being adverse to durability, unless the concrete is smooth, impervious, and able to resist these deteriorating agents, the experts had chemical analyses made of the muskeg

waters, and of the materials forming the muskegs and underlying soils. These investigations covered both the Laurentian formation which underlies the greater part of the length of the aqueduct, and the limestone which occurs towards its westerly end. The results show that the sulphates and sulphuretted hydrogen were not present in the former and in minute quantities only in the latter. The method adopted of constructing the aqueduct in a shallow trench, permitting of the drainage of the muskegs nearly as low as the bottom of the aqueduct, will allow very little ground water to come in contact with the concrete. The report doubly emphasizes the use of good materials as a further safeguard against any injurious effects.

For the first 9 miles of the route the land through which the aqueduct will pass is higher than Indian Bay, and necessitates a deep summit cut, for gravity flow. This is shown to advantage in Fig. 4. From this point the gradient is quite variable, although down-grade all the way to Transcona; hence the varying sizes and cross-sections of the aqueduct, as shown in Fig. 5, ranging from one 10 feet wide and 9 feet in height with a sec-

aqueduct reinforced with steel has also been adopted, so that this portion will withstand the pressure resulting from building it 10 feet or more below the regular grade line. The diameter of this particular section is 7.2 feet. At Birch River there is the alternative of carrying the aqueduct over, instead of below, the surface of the water.

At the waste weirs, provision will be made to dispose of any excess of water over the capacity of the pipe line, leading from Transcona into Winnipeg, which might accidentally be permitted to enter the aqueduct at Indian Bay. This may be accomplished by placing stop-planks across the aqueduct to stop or throttle the flow through it. Blow-offs, other than at the locations mentioned above, will be placed where opportunity offers, being convenient for use during the construction of the aqueduct, and while it is being repaired, and to be used in emergencies when the aqueduct is in service.

For the last 26,000 feet of the concrete reservoir leading toward Transcona, the section of aqueduct to be used is designed to withstand the internal pressure that will develop when it is necessary, at some time in the future, to build a large reservoir there, and to provide a

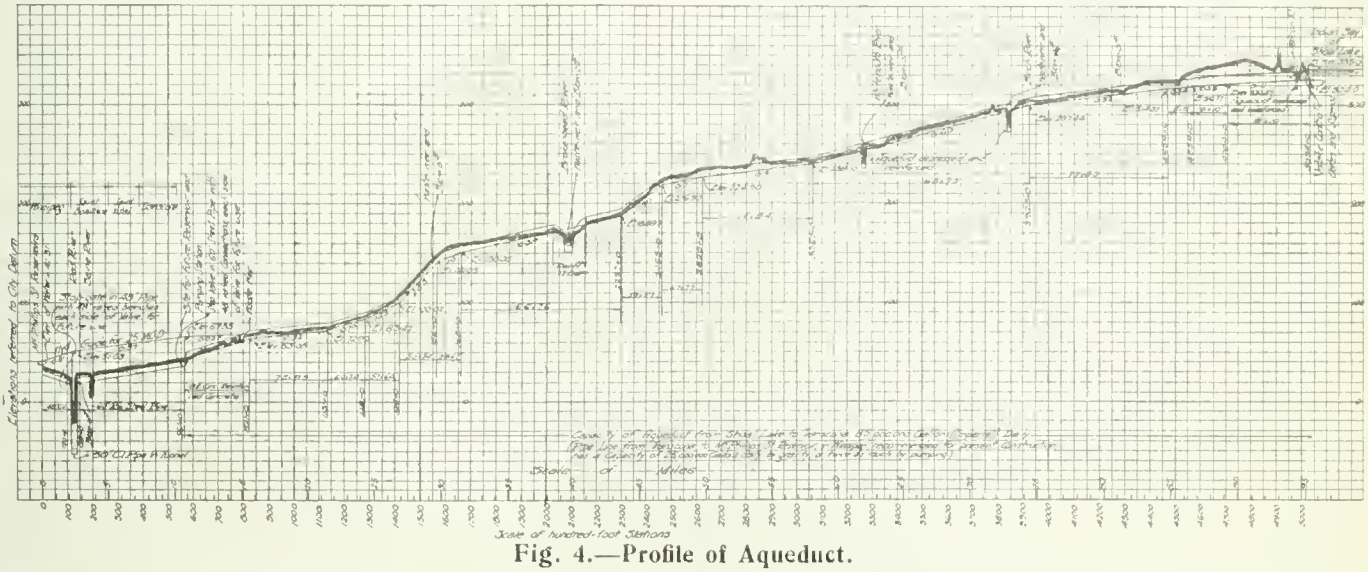

Fig. 4.—Profile of Aqueduct.

tional area of 73.6 sq. ft., with a hydraulic radius of 2.33 feet (used at the summit cut where there is a low gradient) to one 5 feet high and 5 feet wide, with 20.9 sq. ft. cross-section, and a hydraulic radius of 1.24 feet used where the gradient is highest. The profile shows four river crossings, viz., Falcon, Birch, Whitemouth and Brokenhead Rivers, where the aqueduct is depressed and reinforced, and is provided with waste weirs and blow-offs. These crossings require special construction. At the Falcon River depression a pile foundation will be required for about 600 feet, and the depression itself will be 150 feet in length. The top of the aqueduct will be sufficiently low in the water to permit of the passage of boats of light draft. The depressed portion is to be reinforced with steel, and the concrete walls thereat will be considerably thicker than under ordinary circumstances.

The depressions and strengthened sections at Whitemouth and Brokenhead Rivers are similar, although for a part of the distance at the latter crossing, where the muskeg is too steep to permit of the construction of the aqueduct upon a solid natural bottom, a pile and timber foundation will be required. At this crossing also, and through the low-land on either side of it for a distance of 13,000 feet, the circular form of pumping station. This portion of the aqueduct has been designed of circular form, 8 feet in diameter, and provided with steel reinforcement. The section shown in Fig. 6 is designed to withstand the pressure due to 20 feet of water.

As the aqueduct, with the exception of the reinforced portions above mentioned and some other short lengths at river crossings, is not expected to stand any considerable upward pressure on the arch, measures are to be taken to prevent the opening of the sluice gates at Indian Bay to a height which will permit a quantity of water to enter the aqueduct much, if any, in excess of the rate of 25,000,000 gallons daily, which is the limit of the capacity of the pipe line leading from Transcona to the city reservoirs. The waste-weirs already mentioned will act as a further safeguard in permitting the discharge into the crossed streams of excess of water.

The concrete mix recommended for the construction of the aqueduct, for strength, permanency, and water-tightness, is one of Portland cement, two of sand, and four parts of screened gravel. To prevent transverse cracks in the structure, the precaution is to be taken of building in sections not more than 20 feet in length, and where one section joins another, a steel bar about 3 inches

by 1¼ inches will be inserted to act as a water-stop, and prevent leakage at these joints.

It will be noted in the cross-sections of the aqueduct that in each case there is a central wooden box drain and a platform consisting of two thicknesses of 1-inch boards, the upper one being fluted on the under side to furnish channels in which the water may flow from the side to the drain. This arrangement is shown in Fig. 3. The platform furnishes a dry bottom upon which the concrete bottom of the aqueduct will be built and kept dry until it has had time to set. Although the drawing shows a double platform, a single board with grooves in each edge may be used where there is but little water to be taken care of. The boards are to be bedded in sand.

The Steel Pipe Line.—From the end of the concrete aqueduct, near Transcona, a 5-foot pipe line 43,200 feet in length, will convey the supply as far as Red River. This pipe will be of rivetted steel, ⅜ of an inch in thickness. At its upper end a valve it to be provided for shutting off the supply, while above and below this valve there will be branches, each provided with a valve to be used in the future in connection with the reservoir and pumping station to be installed when the 25,000,000-gallon supply to the city becomes inadequate.

Where the pipe crosses the Seine River, a new street has been projected, the design of which provides for the erection of a 30-foot arched culvert, filling over it with earth, and it is intended to lay the steel pipe in this earth.

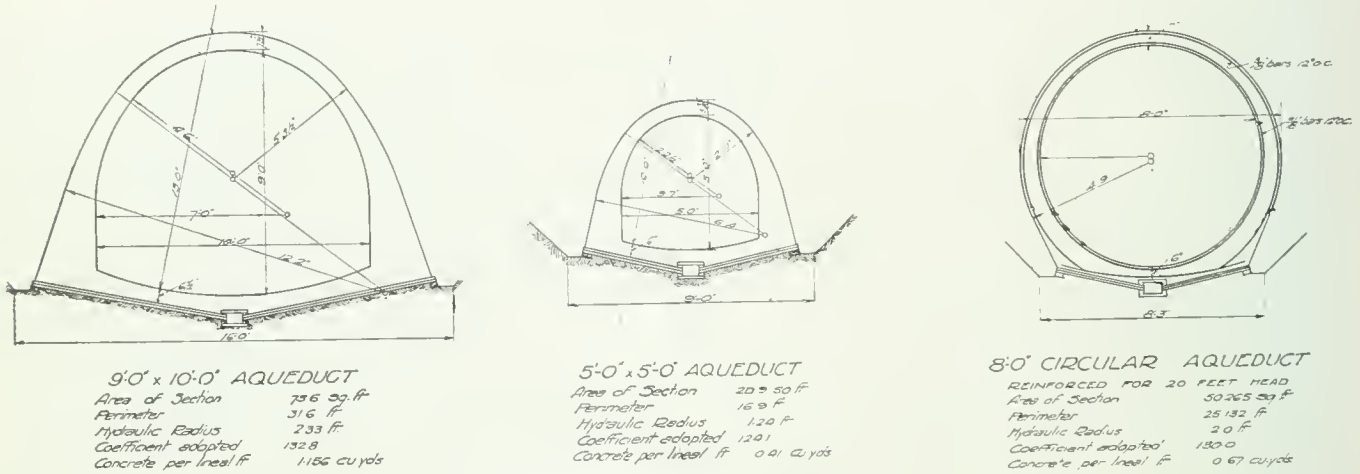
The Cast-iron Pipe Section.—Reaching the Red River, a tunnel extending about 900 feet horizontally across the river from a shaft in Victoria Park to a corresponding shaft in the opposite side, each 75 feet in depth, will carry the supply in a 60-inch cast-iron pipe, 1.9 inches thick, and provided with a special bell about 15 inches long, so designed as to permit the joints between the pipe lengths to be caulked from the inside with lead wool. The tunnel is to be of only sufficient diameter to permit the placing of the pipe. This provides a minimum of 6 ft. 3 in., although the average diameter, owing to the irregularities in blasting, will be considerably more.

All spaces between the pipe and the sides of the tunnel are to be filled with concrete, as far as it is practicable to place concrete, and the remaining space is to be filled by pumping in cement grout, the aim in using such thick pipe and in filling all spaces with concrete or cement grout being to make absolutely secure this portion of the pipe line which will be inaccessible unless the water is shut off, and the pipe is emptied by pumping.

The remaining 12,000 feet of pipe to McPhillips Street reservoir is to be laid for almost the entire length in the city streets, and a 48-in. cast-iron pipe has been adopted. This for the reason that steel is less desirable in city streets than cast-iron pipe, and that a pipe larger than 4 feet in diameter interferes too seriously with other structures. The pipes which are to be laid in the streets will be laid to such a depth as to permit a 4-foot covering of earth.

East of Transcona, where the aqueduct will not follow the streets, but will be laid through the open country, a cheaper and more expeditious plan will be adopted of building it in a shallow trench from 3 to 4 feet deep, where practicable, and covering it to a depth of 4 feet with an earthen banking, the top width of which will be at least 8 feet, and nowhere less than the inside width of the aqueduct, so as to make the slopes of the embankment 2 horizontal to 1 vertical.

Gradients.—For a distance of 33,000 feet (6.26 miles) from Indian Bay, the gradient of the aqueduct has been made so low that is falls only .11 of a foot in 1,000. This low gradient was adopted for this distance to diminish the depth of the summit cut and is the most economical gradient, all things considered. As stated, the aqueduct through this section is 9 feet high and 10 feet wide.



9'-0" x 10'-0" AQUEDUCT

Fig. 5.—Cross-sections of Aqueduct.

For the next 25,000 feet (4.74 miles), the fall per 1,000 is .25 of a foot. The large sized aqueduct, 9 feet high and 10 feet wide, is continued for 15,000 feet of this distance and a smaller aqueduct, 8 feet high and 9 feet wide, for the remainder of the distance. This design is the result of hydraulic computations, which show that with these sections of the aqueduct as planned 85,000,000 gallons daily will flow through the aqueduct when the water in the bay is 3.75 feet below high-water level, provided the water has such a free entrance through the intake and gate and screen chamber that it does not fall more than .25 of a foot in passing through them.

Beyond the three portions of aqueduct above described, the gradient of the aqueduct has been made to follow approximately parallel with the surface of the ground all the way to its end near Transcona, and a size has been adopted for each gradient, with a few exceptions which would give the aqueduct the standard capacity of 85,000,000 gallons per day.

The quantity of water which will flow through the reinforced section of aqueduct, used for the last 26,000 feet, will not depend upon the gradient of the aqueduct

itself, but upon the hydraulic gradient available when a reservoir is built east of Transcona, and its size has been computed accordingly. Somewhat similarly, the next two portions of the aqueduct east of the reinforced portion, covering a total length of 46,000 feet, have been made a little larger than the size due to the gradient of these portions, on account of the possible back water effect from the proposed reservoir.

The flow through the pipe line is, of course, dependent upon the hydraulic gradient and not upon the gradient of the pipes. For a flow of 25,000,000 gallons daily, this amounts to .37 of a foot per 1,000 in the 5-foot pipe and .81 of a foot per 1,000 in the 4-foot pipe, making a total fall through these pipes of the McPhillips Street reservoirs of 26 feet.

Table I. gives various statistics relating to the various portions of the aqueduct, including lengths, gradients, elevations and dimensions of the different sections.

To. T. R. Deacon, mayor, is to be accredited a great deal of the developments which the City of Winnipeg has experienced this year in the interests of a better and a safer supply of water. The city engineer, H. N. Ruttan, has been one of the strongest advocates of the Shoal Lake scheme, and it was largely through his persistent emphasis last year that the thorough and accurate investigation of the project was made, as the prospective cost had vied so strenuously with the very desirable qualities of Shoal Lake as a source of supply as to render the proposition an apparently prohibitive one.

In a succeeding issue *The Canadian Engineer* will describe the extensions which were recommended by the Board of Consulting Engineers, to be provided when the increased consumption of water renders the capacity of the pipe lines inadequate.

Table I.—Lengths, Slopes, Elevations and Dimensions of the Various Sections of the Aqueduct from the McPhillips Street Reservoirs in Winnipeg to Shoal Lake.

Total Distance from McPhillips St. Reservoirs		Length of section.	Dimensions of Aqueduct		Slope in feet per 1,000 feet	Elevation of hydraulic gradient at end of section.	Remarks

503,400	95.35	41			0.00	324.00	Gate and screen chamber.

*13,000 ft. of this length at Brokenhead River Crossing is 7.2 ft. in diameter and reinforced.

TUNNEL THROUGH JURA MOUNTAINS.

The Mont d'Or Tunnel, between France and Switzerland, on which boring operations were begun nearly three years ago, was pierced recently. The two boring gangs, advancing from the Swiss and French side respectively, met and shook hands. It was found that the engineers had calculated the cutting with the greatest accuracy. The tunnel, which is three and three-quarter miles long, penetrates through the Jura Mountains, from Gresne to Vallerbe, thus obviating a seven-mile detour by Pontarlio. It should have been completed two months ago, according to contract, the work, however, being delayed by the tapping of a number of springs, which had to be pumped dry. The flow of water at one time reached 2,200 gallons a second. It is hoped that the new line will be opened early next year.

SPECIFICATIONS FOR CONCRETE MASONRY IN HIGHWAY BRIDGES.

IN September 11th issue of *The Canadian Engineer* there appeared under the heading "Typical Specification for Steel Highway Bridges," a portion of a set of typical specifications issued by the Department of Agriculture of the United States. The bulletin contains, in addition, a few specifications governing the use of concrete in masonry. Generally, it requires the concrete to be prepared and mixed in very strict accordance with specifications and plans, the cement to be of satisfactory standard conforming with Government specifications, not to contain lumps or any indications of exposure.

Aggregate.—The sand is required to consist of dry, clean, quartz grains and not to contain more than 5 per cent. of clay, loam, or other foreign materials. The grains shall be well graded and of such size that all will pass a ¼-inch mesh screen and not more than 20 per cent. will pass a No. 50 sieve.

The coarse aggregate may consist of either broken stone or gravel. Stone shall be sound, hard, and tough, broken to the sizes hereinafter specified, and when used shall be free from foreign material. No weathered or disintegrated material shall be used. Gravel shall be composed of hard, sound, durable particles of stone, thoroughly clean and well graded in size between the limits specified below.

Unless otherwise especially provided, there shall be three classes of concrete, known as class A, class B, and class C.

Class A concrete shall consist (by volume) of 1 part of cement, 2 parts of sand, 4 parts of coarse aggregate, and water. All of the coarse aggregate shall be retained on a ¼-inch mesh screen and shall pass a 1-inch mesh screen. Not more than 75 per cent. shall be retained on a ½-inch mesh screen, and not more than 75 per cent. shall pass such a screen.

Class B concrete shall consist (by volume) of 1 part of cement, 2½ parts of sand, 5 parts of coarse aggregate, and water. All of the coarse aggregate shall be retained on a ¼-inch mesh screen and shall pass a 1½-inch mesh screen. Not more than 75 per cent. shall be retained on a ¾-inch mesh screen, and not more than 75 per cent. shall pass such a screen.

Class C concrete shall consist (by volume) of 1 part of cement, 3 parts of sand, 6 parts of coarse aggregate, and water. All of the coarse aggregate shall be retained on a ¼-inch mesh screen and shall pass a 2½-inch mesh screen. Not more than 75 per cent. shall be retained on a 1¼-inch mesh screen, and not more than 75 per cent. shall pass such a screen.

Mixing.—The cement and sand shall first be thoroughly mixed dry, in the proportions specified, on a proper mixing platform. Sufficient clean water shall then be admixed to produce a pasty mortar. To the mortar thus prepared shall be added the proper proportion of coarse aggregate, previously drenched with water, and the whole shall be mixed until every particle of the coarse aggregate is thoroughly coated with the mortar. Instead of the above method a mechanical mixer satisfactory to the engineer may be employed.

Concrete shall be mixed in batches of such size that the entire batch may be placed in the forms by the force employed within 45 minutes from the time that the first water is applied. No concrete is to be prepared from mortar which has taken an initial set and would require retempering.

Placing.—All concrete shall be carefully deposited in place and never allowed to fall from a height greater than 5 feet. Concrete shall never be deposited in running water, nor in still water, except under the direction of an engineer skilled and experienced in that special work.

As fast as concrete is put into place it shall be thoroughly tamped in layers not more than 6 inches thick, and the portion next to the forms shall be troweled by using a spade, or by other means, to bring the mortar into thorough contact with the forms.

Concrete shall not be deposited when the temperature of any of the materials composing it is below 35° F.; and if during the progress of the work freezing temperature threatens proper precautions shall be taken to protect from freezing all concrete laid within the four preceding days.

Forms shall be so constructed as to continue rigidly in place during and after depositing and tamping the concrete. If during the placing of the concrete the forms show signs of bulging or sagging at any point, that portion of the concrete causing the distortion shall be immediately removed and the forms properly supported before continuing the work. The amount of concrete to be removed shall be determined by the engineer, and the contractor shall receive no extra compensation on account of the extra work thus occasioned. Forms for exposed surfaces shall be constructed of dressed lumber.

All forms shall be left in place not less than 36 hours and all supporting forms not less than 10 days after the concrete has been deposited. These periods may be increased at the discretion of the engineer in charge.

It is understood that all prices for concrete masonry shall include furnishing all materials and properly constructing all necessary forms.

When the work of laying concrete is to be interrupted for a period greater than one hour and there are no reinforcing rods projecting, provision for a joint shall be made in the following manner: Square timbers 8 by 8 inches, or some other suitable size approved by the engineer, shall be bedded in the concrete throughout the length of the course for one-half their thickness and allowed to remain until the concrete has taken its initial set. When the work of laying concrete is resumed, the timbers shall be removed and the surface thoroughly wet. No joints will be permitted in reinforced-concrete beams, and in floor slabs the joints shall be vertical and parallel to the main reinforcing bars.

Forms covering surfaces of the concrete masonry which are to be exposed shall be removed immediately after the expiration of the period of time necessary for such forms to remain in place, as fixed by the engineer, and all crevices which may appear shall be filled with 1:2 cement mortar. These surfaces shall then be finished with 1:2 cement mortar and a wooden float, so as to present a smooth, neat appearance.

Reinforced Concrete.—All reinforced arches, beams floors, parapets, guard rails, and all concrete masonry measuring less than 9 inches in thickness shall be made of class A concrete, unless otherwise specified on the drawings or directed by the engineer in writing.

Unless otherwise specified on the drawings or in writing by the engineer, class B concrete shall be used for all abutments and wing walls the thickness of which is not less than 9 inches.

Class C concrete shall be used for all footings and cut-off walls, unless otherwise specified on the plans or directed in writing by the engineer.

Unless otherwise specified on the drawings, all reinforcing steel shall consist of bars which have been deformed in some approved manner. No plain bars will be permitted except as shown on the drawings or directed in writing by the engineer.

The steel bars shall have the net sectional area and shall be placed in the exact positions indicated on the drawings.

Unless otherwise specified on the drawings or in writing by the engineer, all reinforcing bars shall be of medium steel having an elastic limit of not less than 35,000 pounds per square inch, and shall be sufficiently malleable to withstand bending cold with a radius equal to twice the diameter or thickness of the bar through 180° without fracture.

When placed in the concrete, the reinforcing steel shall be free from grease, dirt, and rust, and it shall be the duty of the contractor to provide means for properly cleaning the steel.

Thorough contact of the concrete with every portion of the surface of the steel shall be obtained.

Unless otherwise specified on the drawings or in writing by the engineer, necessary splices in reinforcing bars shall be effected by overlapping the ends of the bars a distance equal to 40 times their thickness or diameter.

Inspection and Testing.—All materials used in connection with the work being done under these specifications shall be purchased especially for that work. The contractor shall furnish the engineer with complete copies of all orders for materials, and shall make all orders subject to the engineer's approval of the materials.

The engineer or his representative shall stamp each accepted piece or parcel with a private mark, and any material not so stamped may be rejected at any stage of the work. The engineer's acceptance, however, does not relieve the contractor from responsibility for faulty material or workmanship and wherever such faulty material or workmanship is discovered is shall be repaired or removed and replaced, as the engineer may direct, by the contractor at his own expense.

The contractor shall furnish the engineer or his representative all facilities for testing materials and workmanship at the shop where material is fabricated, and shall notify the engineer well in advance of beginning the shop work.

The contractor shall furnish all facilities for testing the weight and quality of all material at the mill where it is manufactured. He shall provide, free of cost, a suitable testing machine for making the tests and such test specimens as the engineer or his representative may require.

Erection.—Unless otherwise specified in writing by the contracting parties, the contractor shall furnish all labor, tools, machinery, and materials for erecting the bridge complete in place and ready for traffic, in accordance with these specifications and the plans furnished or approved by the engineer.

The contractor shall do all necessary hauling, set all stone or anchor bolts, remove existing structures when necessary, and perform all other incidental work for which express provision has not been made.

The contractor shall so conduct all his operations as not to interfere with the work of other contractors or close any thoroughfare by land or water except by written consent of the engineer.

The contractor shall assume all risks of damage or accident to persons or property prior to the final acceptance of the finished structure.

The contractor shall remove all false work, piling, and other obstructions produced by his operations, and shall perform any additional work necessary to produce a sightly appearance in the immediate vicinity of the structure.

ANALYSIS OF COALS.

An increasing proportion of the coal consumed in the power stations and the larger manufacturing plants is now being purchased under specifications based on chemical analyses and calorimetric determinations of heat units. In the purchase of fuels many matters that have been left to chance are now carefully investigated. It is the aim of mechanical engineers to construct furnaces and to arrange the heat absorbing surface in a furnace with reference to the peculiar character of the fuel which is to be burned. Noting the composition of the fuel and constructing the furnace with reference to it, he can assure efficient and smokeless combustion. Moreover, in any particular market, the choice of coal generally is limited by its quality and by freight rates to one or two fields in which the character of the coal bed is comparatively uniform. Having on hand a representative analysis of the coal from a given bed in any particular district, the engineer can determine whether the coal he receives comes from the bed and the district stated, and whether it is being prepared for market as carefully as it should be. Wide variations in the composition and heating value of the coals from different districts and from different beds make analyses that are comparable, because of the care taken in sampling and analyzing the coal, almost indispensable to engineers having to install boiler or gas-producer plants in different cities, and also to railroads and steamboat companies.

In Bulletin 22, entitled "Analyses of Coals in the United States," the Bureau of Mines has issued information that designing and operating engineers and industrial superintendents will find of great value. Some five thousand samples of coal taken from fifteen hundred coal mines were considered in the report, and much reliable data are presented regarding the chemical composition and heating value of the coals.

The report is in two parts, one giving the methods used in collecting and analyzing the samples, and the results of the analyses, and the other giving the exact location from which each sample of coal was taken, together with a description of the characteristic features of the coal bed at the point of sampling, the nominal capacity of the mine, and such notes on the preparation of the coal as might be useful to consumers. The data contained in these two volumes is not equalled in scope and detail and in value for comparative purposes by the figures that have been published by any other coal-producing country in the world. The Governments of some of these countries have published analyses of coals from different mines and from different districts but, with few exceptions, the samples of coal were not collected and analyzed under a uniform system that would make the results comparable in all respects, and no country has attempted to publish such a large number of analyses that would be comparable, because of the care taken in collecting and analyzing the samples.

ELECTRIC DRIVE IN MACHINE SHOPS.

At the Philadelphia meeting of the American Institute of Electrical Engineers, Oct. 13, 1913, Mr. Charles Fair read a paper dealing with the possibilities of the electric drive for machine tools. He points out the two important questions before the manufacturer as being to increase products and to decrease cost. Since labor is the greatest cost of production, then, where machine tools are a considerable factor in the production, maximum output from the tool is a necessity. Tools that are limited in production because of a lack of power at the tool are a source of expense to the manufacturer. Power cost is low while labor cost is high. The well designed motor-driven machine of to-day shows the motor as one of the main elements of the tool, it having done away with much of the old mechanical drive, and is no longer a mere adjunct to the tool. Mr. Fair's paper is as follows:—

The importance of the motor drive for the machine shop is every day becoming more evident. Due to the great improvement in motors, accessories and methods of application and to the large number and variety of motor-driven tools in service to-day, the relationship of motors and control to machine tools is much better understood by the machine builder and the user than heretofore and, consequently, comparatively little trouble is experienced with either motors or control for the ordinary type of machine tool. Misapplications of both motor and control occur occasionally due largely to insufficient or unreliable information regarding the characteristics of the machine, but the number of these misapplications is relatively small. The tendency to both over- and under-motor machines is constantly growing less, owing to the large number of tests made and to accurate information available. There is still, however, a tendency on the part of some machine builders to over-motor their machines either with the mistaken idea of the strength of their machine or with the idea that possibly prospective customers will be impressed with the enormous power that their "heavy type" machines take. Conversely, other manufacturers want to show how little power it takes to operate their "very efficient" machines and consequently get into trouble. These extremes are gradually disappearing and a more normal condition is taking its place. In a comparatively short time the greatly over-motored and under-motored machine will be a thing of the past, at least so far as the general type of machine is concerned. A number of manufacturers have already recognized three ratings of motor drive on certain of their machines; namely, heavy, medium and light. Much of the existing trouble in motor applications to special machines or to machines rigged for special operations could easily be avoided if only preliminary tests were made with a temporary motor before making the permanent installation. A not uncommon source of trouble, and one that could easily be avoided, is that of attempting to increase considerably the productiveness of a tool by speeding up the machine, increasing the cuts and attaching automatic feeding devices, etc.; all of which increases production but, in doing so, the motor is often overlooked and, if the tool were originally under-motored and the power is not increased, trouble is apt to result. Increased production often calls for an increase in power although there are cases where this is not true.

To increase production and to decrease cost are two important questions continually before the manufacturer to-day. In the majority of cases labor is the greatest cost of production, thus where machine tools are a considerable factor in the production, the importance of obtaining maximum output from the tool is evident. Although the advantages of the motor drive have been dwelt upon at length numerous times, a brief statement of the advantages derived from electrical installations will perhaps be worth repeating:—

Maximum output of tool due to greater power and overload capacity.—Too much stress cannot be laid on maximum output of tools.

Closer speed regulation.—Allows maximum speed for varying materials and size of work.

Power distribution not only for the tools, stationary or portable, but for cranes, lights, etc.—This means that power and light can be had in any part of the building, buildings or yard, permanent or temporary without regard to structural conditions. Numerous belts obstruct light, whether natural or artificial.

Elasticity in the arrangement of tools.—Tools can be arranged to the greatest advantage for sequence of operation in routing work and for light as well as for compactness when necessary.

Ease of adding new tools and of moving and rearranging tools.—Ease of adding new tools means a great deal in growing plants. Rearranging becomes necessary after reasonable growth or to improvements in methods of manufacture which call for a better routing of work.

Head room for cranes, hoists, etc.—For example, note the expensive manner in which work is often handled because of belt or shafting interference with the installation of cranes or hoists.

Facility for running only such tools as are required, for overtime work.

To a large extent the elimination of belts and belt troubles.

Unobstructed light and sanitation.

Under modern structural conditions, avoidance of the well-understood difficulties of line shaft installations in concrete buildings.

The general use of high-speed steel has made it not only possible, but necessary, for economical production that the cutting speed be increased in order to meet competition. Increasing the cutting speed means more power and while much has been said from time to time regarding the increased production and saving in power due to applying power direct to the tool, yet the writer has very serious doubts if anything like the real importance of this direct application of power is realized in many cases even by those who are advocating it. For instance, the saving of power is looked upon generally as a matter of how much can be saved of the transmission friction load, and though this saving may amount to 50 per cent., it is in many cases only a part of the real saving, as proved by numerous tests made by the writer.

The slipping, due to a belt not being able to pull its cut, means waste power and loss of production. If the cut be heavy enough the maximum slip will be reached when the machine is stalled, the power input remaining approximately the same, the loss being entirely one of friction due to slip in the belt. A familiar illustration of the above is that of an operator decreasing the depth of his cut on account of slow down, because the belt will

not carry the load. A natural answer to this would be to increase the size of the belts. This will suffice in some cases, but there are numerous instances where either there is not room to increase the width of the belt or if step cones be used the number of steps will have to be decreased and means (such as multiple counters or additional gearing) taken to complete the speed range. Further, it is difficult to shift large belts, and this method generally results in much loss of productive time. Tools that are limited in their production because of the lack of power at the tool are a source of great expense to the manufacturer, not only on account of the unproductiveness of the tool, but on account of the excessive labor expense due to the additional time required. The power cost of the production is comparatively small, roughly, varying from one to three per cent., while the labor cost is usually a very heavy item of the production cost, say, fifty per cent. or upward. If, therefore, by increasing the power on a given tool its output can be increased, the conclusion is obvious.

Up to a few years ago in the majority of shops where motors were used they were usually belted to the lineshaft or countershaft of the tool. Adjustable speed motors were not so commonly used then as now nor were they made in the great variety of sizes and speeds now obtainable. To-day, especially in the case of new tools with their requirements of high power and close speed regulation, it becomes not only more convenient, but in many cases almost a necessity to apply the motor directly to the tool.

In driving tools with individual motors it will be noted that the motor not only supplies the power and speeds best adapted to the tool, but that in the case of the variable speed tools the speed range of the adjustable speed motor, alone, will in many cases cover the entire speed range of the tool. The motor and its controlling apparatus should, whenever possible, be connected direct to the tool, thus making a compact unit which has also the additional advantage of allowing the tool to be moved by simply disconnecting the leads and connecting them in the new position. In the case of portable tools this, of course, is an absolute necessity.

Many tests have been and are being made to determine the kind and horse-power of motors that should be used for different types and sizes of tools, but up to the present time the motor is generally thought of only as a means of driving the tool and not as to its possibility of becoming one of the main elements of the tool construction. Recent motor improvements will produce many new designs in tools with corresponding higher efficiencies.

While there are numerous motor applications to machine tools which are a decided credit to the machine designers and for which due credit should be given, there are still many motor applications where it is only too plainly seen that the motor is an ofter-thought and thus much of the advantage of the application is lost. In order to derive the greatest advantages from the motor drive, the motor should, as far as possible, be direct-connected to the machine. For example, a recent up-to-date motor application to a machine in common use and one that had been motor-driven for several years, abolished belts, three sets of bevel gears, two splined shafts and considerable other gearing; the motor being applied directly to the machine spindle. There are to-day many cases where motors are driving machines through unnecessary auxiliary apparatus such as belts, gearing, etc. This additional apparatus not only takes up valuable floor space and wastes power, but fails to give the maximum output available when the motor could be connected directly to better advantage and in some cases at actually less cost. From the foregoing it will be seen that the advantages derived from an up-to-date direct method of applying the motor not only increases the productiveness of the tool, but decreases the actual power required to the extent of the friction load short circuited, and also decreases the first cost of the motor on account of the less capacity required. The writer knows of cases where improved drives have cut the power required to half and even less. A cheap first cost is often an expensive investment.

The advantages of the individual motor drive for large tools and for certain of the smaller tools have been conceded for years, but there are many tools where either the cost of the motor or the cost of applying the motor to the tool on account of the construction of the machine is prohibitive. The motor should be a part of the tool rather than a mere addition to it.

Better drives are possible now than formerly, due to the greater motor speed ranges obtainable and to the decrease in dimensions per horse-power of the motors, to more perfect balance of the rotating parts and, to a certain degree, to improvements in gears which allow higher speeds without excessive vibration and noise.

The improvements in control appliances have kept pace with the motor development. Much more exacting requirements of both motor and control are now demanded. Motors driving machines reversing ten times per minute, twenty-four hours per day are now not uncommon. Duty cycles that were impossible to meet only a short time ago are now not only practicable but common. With the great variety of motors and controllers now on the market and the large quantity sold, sometimes without the manufacturer even knowing for what service they will be used, it would be surprising if trouble did not occasionally occur.

Much of the success of a motor-driven machine depends on its control. Magnetic control, which is coming into more general use than formerly, somewhat complicates the control situation. While the possibilities of magnetic control are infinitely greater than the older types of control, likewise the chances for misapplication are greater. However, as the characteristics of the different types of control become better known these complications will disappear.

In the report of Mr. J. McLeish, issued by the Department of Mines, Ottawa, on Economic Minerals and Mining Industries of Canada, the production in 1912 of the three following minerals was as follows:—Lead, 35,763,476 lbs., at the value of $1,597,554; Corundum, 1,960 tons, at the value of $239,091; graphite, 2,060 tons, at the value of $117,112.

In the report of Mr. J. McLeish on Economic Minerals and Mining Industries of Canada the following statistics are given for 1911 and 1912 for the total value of the outlay of clay products in the following provinces, thus:—In British Columbia, for 1911, $675,505, for 1912, $996,568, showing an increase of $321,063; in Alberta, for 1911 $1,052,751, for 1912, $1,356,184, showing an increase of $303,433; in Ontario, in 1911, $3,916,575, in 1912, $4,864,700, with an increase of $948,125; in Quebec, in 1911, $1,341,467, in 1912, $1,680,300, with an increase of $338,833; in Nova Scotia, in 1911, $274,249, in 1912, $272,053, showing a decrease of $2,196.

SWEDISH WATER POWERS AND THEIR UTILIZATION.

In respect of total water power Sweden ranks third among European countries, coming next after Norway and Austria-Hungary. Dr. Helmer Key, a recent writer on the trade and resources of Sweden, states that the water power is equal to 4,000,000 h.p. or 5,000,000 h.p.; while that of Norway is five or six millions, and that of Austria-Hungary four to six millions of horse-power. The Swedish waterfalls are more difficult to exploit than those of Norway, which are usually higher and more compact; but have often the advantage of flowing from the great lakes, which form natural storage basins. The horse-power already harnessed amounts to 600,000 or 700,000 h.p., of which about half is converted into electricity, to be transmitted to a distance, and the rest is directly employed upon water wheels for use on the spot or at a short distance. Almost all the towns are lighted by electricity, or will be so lighted shortly. A great part of Central and Southern Sweden is now intersected by electric conduits belonging to the State or to private enterprises. Electric energy is frequently used for small industries and for agriculture, though for the latter purpose it is far from general. The Government power stations are much more important than the private concerns. In 1893 the State was whole or part proprietor of 800,000 h.p. of waterfalls, and since that date many more falls have been acquired. A plan has been elaborated for electrifying the railways, but can only be completed in the distant future. A power station has been erected at Trollhättan, to tap one of the largest falls in Europe, yielding about 200,000 h.p. The State has alreads invested nearly a million sterling in the enterprise. It has been intended to transmit part of the current at high tension to Copenhagen, but home consumption seems likely to render this unnecessary, and it is expected that the power provided by this fall will act as a potent stimulus to industry in South and Central Sweden.

Probably the industries which will benefit most from the utilization of water power are those connected with iron and steel. Other metal industries, too, as well as the industries which use timber for their raw material, will doubtless receive great encouragement. For centuries Sweden has been one of the most important mining countries. Time was, indeed, when it was the chief producer both of iron and of copper. The production of copper is now small, for the well-known Falun miners are becoming exhausted. But the output of iron ore has never been so great as it is to-day. The Swedish smelting industry suffered severely from the discovery that iron ore could be smelted with coke instead of with charcoal; but in recent years the output of pig-iron and steel in Sweden has increased rapidly, partly because the native ores are exceptionally pure, and the demand for high-grade steel enables charcoal smelting to be conducted profitably. The mean production of pig-iron grew from 177,000 tons per annum in the years 1856-60, to 471,147 tons in 1891-5, to 528,255 tons in 1901-5, and to 615,778 tons in 1907. The extent to which the crude ore is worked up in Sweden is, however, still very limited. A large amount of ore is exported in the raw state, mainly to Germany. Of the pig-iron produced in Sweden a large amount (134,000 tons in 1910) is also exported, though it is true, on the other hand, that a considerable quantity of foreign pig-iron for foundry purposes is imported. About 60 per cent. of the pig-iron produced in Sweden is said to be manufactured into steel—the best steel in the world. The iron smelting plants consist of a curious mixture of large and small furnaces, the new existing side by side with the old, but the old furnaces are rapidly being driven out of the trade. The use of electricity in the smelting of iron and other ores is one of the most momentous questions of the day in Sweden, for the solution of the difficulties connected with this matter would signify that a further step had been taken towards counteracting the absence of coal. Already water power, converted into electric energy, performs many of the same industrial functions as coal, but the progress of invention can, of course, never make the two completely interchangeable. Some success has already been achieved in the smelting of iron in electric furnaces during the last few years. As a general rule, however, the electric process is suitable only for making iron of good quality, and the process can only compete with blast furnace smelting if water power is cheap. Phosphorus is not eliminated by the electric process, but as the consumption of charcoal, which contains phosphorus, is barely one-third of what is used in ordinary blast furnaces a smaller quantity of phosphorus is found in the pig-iron. Sulphur is not eliminated either in electric smelting, and to produce the best quality of iron it is necessary to use ore with little or no sulphur. Electric pig-iron is suitable for conversion into steel in open-hearth furnaces.

The most important iron mines in Sweden are situated in the province of Norrbotten, within the Arctic circle, in a district which, until the opening of the iron mines, was inhabited only by Nomad Laplanders. The deposits are amongst the largest in the world, and are believed to contain several thousand millions of tons of workable ore. They have been known for centuries, but their exploitation dates only from 25 to 30 years ago, when a railway was built to carry the iron to the coast. The most important mines are those of Gällivara, Luossavaara, and Kürunavaara, the two later forming part of the same deposit. At many points the ore crops up on the surface. The Tuolluvaara mine is another important mine, and is exploited on behalf of some blast furnaces in Central Sweden. There are several mines belonging to the State. The Norrbotten ores all contain a very high percentage of metal, amounting in every case to at least 60 per cent., and sometimes 68 per cent. or 69 per cent. or more. The amount of phosphorus is also usually high, but there is some ore with a proportion of only .05 per cent. of phosphorus. The proportion of sulphur rarely exceeds .05 per cent. to .08 per cent. The iron district of Norrbotten is owned by the Trafikaktiebolaget Grangesberg Oxelösund, a company which forms a sort of iron ore trust. It does not, indeed, control the Swedish market, but is said to exercise a close control over the export of Swedish ore, or at least of the ore rich in phosphorus. In 1907 an agreement was reached between the State and the company regulating the export of ore. The company was to have the right to increase its export each year until the end of 1921, in such a manner that the total export in 1921 and during each of the following 10 years would be 5,100,000 tons. At present only a very small part of the Lapland ore is smelted in Sweden. The rest is exported, principally via the port of Narvik, which is open all the year round, to England, Germany, Belgium, and France. In 1909 the United States began to buy Swedish ores, and it may be expected that the new American tariff will encourage this trade.

PRODUCTION OF POLES AND CROSS-TIES, 1912, IN CANADA.

THERE were 608,556 wooden poles reported in Bulletin No. 39, Forestry Branch, Department of the Interior, as having been purchased in Canada in 1912. This number is an actual increase of 22,853 poles, or 3.9 per cent. increase over the figures for 1911. While this increase is slight, it follows a decided decrease from 1910 to 1911. The average pole has a life of at least ten years, and the demand for poles is, therefore, more or less intermittent, depending on the building of new pole-lines.

Altogether nine kinds of wood were reported for poles in 1912, with Eastern cedar heading the list as in past years. Cedar has been, and probably will be for some time, the most popular wood for telegraph, telephone, and other pole-lines, although the purchases in 1912 show a decrease. Wood for this purpose need not be especially strong or hard, as there is little or no mechanical strain to be endured. Durability in contact with the soil, lightness and a slender tapering form are most essential, and cedar seems to fit those requirements better than any other native wood used in an untreated state.

The use of the British Columbia species of cedar has increased in the last few years with the decrease in the supply of poles of the Eastern species in the greater length-classes. While these poles are not so strong or so durable as those of Eastern cedar, they can be obtained in greater lengths, and the source of supply is more easily accessible. The two species of cedar together formed over 85 per cent. of the total.

Balsam fir was reported for the first time in 1912. This wood is being used more and more each year for all purposes, especially in the Maritime Provinces where the supply of pine is beginning to fall below the demand. As far as form and lightness are concerned, this species should make excellent pole material if its lack of durability were made up for by some preservative treatment. Increases are noted in the use of Western cedar, tamarack, spruce, and chestnut, with balsam fir added to the list; and decreases in the use of Eastern cedar, jack pine, Douglas fir and hemlock. No poles were reported in 1912 of red, white or yellow pine.

The average value of poles in 1912 was $1.83, an increase of only 3 cents over 1911. A slight increase was recorded in the case of Eastern cedar, and other increases were in the value of poles of spruce and jack pine. All other kinds of wood decreased in value and the balsam fir reported in 1912 was valued at an average price below the general average for 1911.

Steam railways, and telephone and telegraph companies reported the purchase of 549,560 poles in 1912. This number is an increase of 5.4 per cent. over the total for 1911, and is noticeable in the cases of Western cedar, tamarack, and the newly added material, balsam fir. All other woods show a decrease in number, although Douglas fir and chestnut were added to the list of woods purchased by steam railways. The average value of $1.51 per pole is an increase over that of 1911. The average values of poles purchased by this class of pole-line companies is always less than with the electric railway, power, and light concerns, as the steam railway and telephone companies are usually closer to the source of supply and purchase their poles in greater quantities. They also use more poles of the shorter length-classes. These companies used all the poles purchased of balsam fir, tamarack, jack pine, Douglas fir, and chestnut. They purchased 90.3 per cent. of all the poles used.

The electric railway, power, and light companies purchased a total of 58,996 poles, 9.7 per cent. of all the poles purchased in 1912. This number is a decrease of 5,135 or of over eight per cent. from the total in 1911. These companies used only four kinds of wood, namely, cedar (Eastern and Western), spruce, and hemlock. Hemlock was not reported in 1911 by these companies, and poles of Douglas fir, chestnut, yellow pine, and tamarack reported in that year were dropped from the list in 1912. The electric companies, as a rule, purchase the best class of poles of the greatest length and seldom obtain their supply locally. These facts are probably responsible for the high values, the average value per pole of $4.79 representing an increase of 24 cents over 1911.

Of the total 608,556 poles, 66.1 per cent. were from 20 to 25 feet in length and were valued at $1.15. Over twenty per cent. were in the 26-to-30-foot class, and were valued at an average of $2.42. In the 31-to-35-foot class, 7.8 per cent. of the poles were placed, and these were valued at $4.01. The 36-to-40-foot poles formed 3.4 per cent. of the total, at $5.38, and the poles of 40 feet and over, at a value of $6.68, made up the remaining 1.5 per cent.

Cedar poles formed the greater part of each length-class and made up practically all the poles in the greater length-classes (36 feet and over). Tamarack and spruce poles were also used in the greater length-classes and formed a large per cent. of the poles between 26 and 35 feet. The jack pine poles were all in the 26-to-30-foot class and practically all the poles of Douglas fir, chestnut, and hemlock were less than 25 feet in length.

The spruce and chestnut poles in the greatest length-class (40 feet and over) were purchased for special purposes, and their low prices do not indicate their relative value.

Many of the pole-line companies use preservative treatments of different kinds to prevent decay and insect injury. These include impregnation of the butts of the poles with creosote, zinc chloride and other chemicals. In some cases the bark is left on that part of the pole which comes into contact with the soil, and this tends to increase the life with some kinds of wood. Painting the butts of the poles with hot tar or creosote will increase their life by several years. Many companies have found that the increased life which is secured by preservative treatment brings about a considerable saving in the annual cost of the upkeep of a pole-line. By thorough treatment with preservatives many non-durable woods, such as balsam fir, are being used satisfactorily where their use in an untreated state would not have been possible.

Cross-Ties.—There was purchased in Canada in 1912 a total of 21,308,571 cross-ties. This was an increase in actual numbers of 6,919,347, or a 48.1 per cent. increase over 1911. This increase took place on almost all the railways in Canada and was especially noticeable on transcontinental lines.

Nineteen different kinds of wood were used, with jack pine still leading. The use of each material increased from 1911 with the exception of Eastern spruce and red pine. Balsam fir and Western spruce were added to the list of woods in 1911, and poplar and black ash were dropped.

The use of the cedar tie has varied greatly from year to year. In 1908, 1909, and 1910, cedar ties headed the list, although the numbers purchased showed decreases each year. In 1911 cedar ties formed only 10 per cent. of the total and fell back to fourth place on the list. In 1912 the use of this material increased by some 1,898,710 ties, and this wood moved up to second place on the list, forming 15.6 per cent. of the total.

Douglas fir has steadily increased in use since 1909, when data concerning its use were first obtained. Oak and the other five hardwoods—chestnut, beech, maple, birch, and elm—have also increased remarkably. There seems to be a tendency on the part of the management of older-established steam railways to reduce the use of soft, light material for cross-ties, especially where fast trains and heavy rolling stock are used. Some of the eastern roads have ceased to purchase cedar, pine, hemlock, and tamarack ties and use only the hardwoods. The use of imported hard pine has increased with the hardwoods, and that wood was used in making 3.1 per cent. of the ties purchased in 1912. Western larch formed 5.6 per cent. of the total number, over a million ties of this wood having been purchased.

The average value of ties, at the point of purchase, increased from 39 to 44 cents in 1912. Increases are noted in the case of jack pine, cedar, hemlock, tamarack, Eastern spruce, chestnut, beech, maple, white pine, birch, red pine, and elm. The increases in the values of beech, maple and birch were probably due to the fact that ties of these three materials were treated chemically in considerable numbers to prevent decay, and their cost materially increased on this account. The decreases were in the values of Douglas fir, oak, hard pine, and Western cedar. Western larch ties were purchased at the same price as in 1911.

The values in all cases, being based on the cost at the point of purchase, can never be considered to represent exactly the relative values of the different kinds of wood for cross-ties. So many variable factors enter into this cost that only in those cases where ties of a certain kind of wood are used in large numbers can the values be said to indicate the intrinsic value of the material.

Steam railways in 1912 reported the purchase of 20,825,209 ties, this number forming 97.7 per cent. of the total for all Canada. The total is an increase of 7,025,227 ties, or an increase of 50.9 per cent. over 1911.

Steam railways paid an average price of 44 cents for their ties as compared to 50 cents paid by the electric lines. The steam railways paid less for every kind of wood used by both classes, with the exception of Eastern spruce. These companies are usually closer to the source of supply, buy in greater quantities, and have better facilities for transporting their tie material than have the electric roads. The steam railways used all the ties purchased in Canada in 1912 of the following kinds of wood: Western larch, chestnut, beech, maple, birch, red pine, and balsam fir.

It is interesting to note the increased use of hardwoods by steam railway companies. In 1911, woods such as oak, chestnut, beech, maple, birch, elm, and black ash together formed only 1.8 per cent. of the ties purchased. In 1912 this percentage increased to 6.7 per cent. through increased purchases of 1,148,578 hardwood ties.

Electric railways in Canada reported having purchased 483,362 cross-ties in 1912. This is a decrease of 18 per cent. from 1911, and, where the purchases of these railways in 1911 amounted to over four per cent. of the total, they formed less than three per cent. in 1912. As stated previously, the values of ties of every kind of wood used by both classes of roads were greater in the case of steam railways, with the single exception of Eastern spruce.

The greater part of the material used by these companies was of the softer, lighter woods. Coniferous woods formed together 99.4 per cent. of the total. The only hardwoods used were oak and elm and these together formed only 0.6 per cent. of the total. Imported hard pine, however, is used to a slight extent, and this material is, in reality, much harder than many of the native so-called hardwoods.

Decreases in the number of ties purchased by electric railways are noticeable in the case of cedar, Douglas fir, oak, and white pine; and these woods together form the bulk of the material used. Increases are seen in the use of hemlock, tamarack, jack pine, and Eastern spruce.

Ties of Western cedar, Western spruce, hard pine, and elm were reported for the first time in 1912. The use of red pine, and chestnut was not reported by electric roads in 1911. These companies used all the Western spruce ties reported in 1912.

Preservative Treatment.—Many Canadian railway companies are now beginning to realize the value of preserving at least a part of their tie material from decay and insect injury. The practice of chemical treatment of railway ties has been carried on by railways in the United States for some years with apparently satisfactory results.

The practice in Canada is just beginning, but is increasing rapidly with the increasing cost of tie material and the constantly decreasing supply. In 1910 practically no treated ties were used by Canadian railways. In 1911 some 206,209 ties received chemical treatment before being placed in the roadbed. This number, while forming only 1.4 per cent. of the total number of ties used, was, nevertheless, an indication of the increase in this particular form of conservation. In 1912 a total of 1,818,189 ties were chemically treated. This number forms 8.5 per cent. of the total number of ties purchased. Steam railways used 1,798,189 of these treated ties and electric roads used 20,000.

The treated ties were mostly hardwoods, as it has been found more economical to treat the heavier, stronger woods than those which are liable to fail from mechanical wear before they have time to decay. The greatest actual saving by preservative treatment is found in the use of the so-called "inferior woods," provided that these are properly protected from mechanical wear. Until the price of the durable woods becomes excessive, the railway companies will not resort to expensive treatment of inferior woods on account of this cost of protecting them from mechanical wear.

SERIOUS RIVER POLLUTION IN SCOTLAND.

During the recent drought the necessity of purifying some of the rivers in the Border district of Scotland was very obvious. In one short stretch of the River Ettrick, extending for about a quarter of a mile opposite the burgh of Selkirk, five spinning mills, four dyeworks and seven tweed-weaving factories were discharging waste liquids into the river or into a mill lade which in turn discharged into the river; while the burgh gas works stand on the edge of the mill lade. The river being very low these polluting materials were not carried away as is usually the case, and the result was an accumulation of the waste matters from all the works and the poisoning of large numbers of fish.

SAND TRAVEL IN HARBORS.

At the Birmingham meeting of the British Association a paper by Ernest R. Matthews, entitled "Harbor Projections and Their Effect Upon the Travel of Sand and Silt" was read to the Engineering Section. The author pointed out that any seaweed projection on a coast has the effect of arresting or more or less checking the travel of the sand, whether the projection is a groyne extending to low-water line, a breakwater, a harbor pier or arm of 1,000 ft. in length, or a natural promontory extending some miles from the coast line. In the case of harbor arms extending at right angles to the coast, this obstruction (especially on a sandy shore) impounds the travelling material on one side and often causes serious erosion on the other side. The sea-front at Yarmouth, Shoreham, Lowestoft and other places has extended seaward during the past half-century, the first mentioned, at an average of 300 ft., due almost entirely to the construction of the harbor.

At Madras (India) 650,000,000 cu. ft. of sand have accreted on the south side of the harbor within a distance of three miles of the harbor, and 450,000,000 cu. ft. of land has been eroded in the north side within a similar distance. The Madras authorities are now contemplating an extension of the harbor seaward at an estimated cost of about $15,000,000 in order to reduce the extent of the silting of the harbor.

The only method of escaping from the impounded material seems to have been to periodically extend the arm of the harbor further seaward, as proposed for Madras. This means a tremendous cost, and the results are often not satisfactory, for as the pier is advanced the shore also advances. It has been suggested that openings should be left through the shore ends of the harbor arms, for the sand to pass through. This is not practicable, for immediately the travelling material passes through the opening the wave behind it does not possess sufficient force to move the material through, especially where the width of the harbor is considerable.

The author suggested that in order to modify this trapping of the sand the piers should not run out at right angles to the coast, or approximately so, but on the side facing the direction of the travelling material should project from the coast at an angle of 45 degrees. The additional area thereby enclosed by the harbor piers could be utilized, among other purposes, for that of wharfage. The travelling material would, he stated, pass around the harbor projection if the plan of the harbor was on these lines, and would supply the coast on the lee side of the harbor with a natural protection of sand and shingle.

In another paper, entitled "The Transport and Settlement of Sand in Water and a Method of Exploring Sand-Bars," and illustrated by experiments, Dr. John S. Owens dealt with certain phenomena accompanying the movement of sand in water.

Sand ripples were shown travelling under the influence of a current; the grains being swept by the current from the back of the ripple and deposited on its face, the ripple-form moved forward with the current by a process of erosion of its back and accretion of its face. This was demonstrated by means of a trough with semi-circular ends and a longitudinal partition in the middle, thus forming two channels. The water was made to circulate up one channel and down the other, and the movements of the ripples were seen on the sand forming the bottom. The formation of quicksands was illustrated by means of a tank containing ordinary sea-sand, and it was shown that when water was caused to flow upwards through the sand the latter acquired all the properties of a quicksand and swallowed heavy bodies placed thereon. The effect of obstacles lying on a sandy bed in the path of a current was demonstrated by means of a model. Stones, models of piles, and improperly made groynes were placed on sand in the path of a current in a small glass tank, and localized erosion around the obstacles resulted in each case owing to the deflection and increased local velocity of the current. The curious effect of suspended matter on the specific gravity of water was illustrated by means of a glass cylinder containing water in which sand was shaken up; it was shown that while the sand was suspended the specific gravity, measured by a floating hydrometer, was raised above that of water. The influence of such a rise in specific gravity in increasing the intensity of impact of the water, and consequently its erosive power, was indicated.

A tall glass tube filled with water was exhibited, and in this bodies of different shape were allowed to sink; in every case, whether discs, rectangular plates or rods, the bodies settled in the position offering the greatest resistance to movement. It was shown that this property might result in more rapid settlement in running than in still water, and also in a cleavage in sedimentary rocks.

A model of an instrument for exploring sand-bars and river-beds, which was also shown, consisted of two tubes arranged concentrically, connected at the top, but separate at the bottom. A cock-and-hose attachment was fixed on the upper end of the inner tube, and a second cock, with a spout, communicated with the top of an annular space between the two tubes. At the bottom the inner tube ended a short distance above the end of the outer tube. Water, if forced down the inner tube, must pass out at the bottom when the cock to the annular space was closed; in this case the instrument sank if placed on a sandy bottom. When at any desired depth the cock to the annular space was opened the water returned up the outer tube, carrying a sample of the sand with it, and delivering the sample from the spout. By means of this instrument the depth and nature of bars and shoals might be easily ascertained.

HAMMERED PISTON RINGS.

If the rings on a piston are not accurately turned and ground, so as to make a steam or gas-tight joint between it and the cylinder walls, the efficiency of the engine will be impaired, power will be lost, and consequently fuel will be wasted. If the tension of the ring is not approximately the same at every part it will exert greater pressure in one direction than in another; the cylinder will be worn out of shape and soon require re-grinding or re-boring. Further, an unevenly-tensioned ring produces friction, and so causes loss of power.

A special form of piston ring which is claimed to possess many advantages is being made by a patented process, by which the rings are of the same thickness throughout their periphery; and as they are machined concentric, they are seated uniformly in the grooves provided in the piston. Special plant is, of course, necessary for the manufacture of the rings, and a patented system of hammering is used whereby, it is stated, the spring action of the concentric rings can be reduced to a minimum without affecting their efficiency. The result of the hammering is to ensure a perfectly even and constant pressure on the walls of the cylinder. The rings, which are of cast iron, are accurately ground after hammering and are supplied ready for use.

LOCK WORK ON THE PANAMA CANAL.

THE placing of concrete in the locks of the Panama Canal has covered a period of approximately four years. It began on August 24, 1909, at Gatun; on September 1, 1909, at Pedro Miguel; and, with the exception of 102 cubic yards laid in 1909, at Miraflores in July, 1910. The end of the fourth year sees the concrete work at all locks practically completed.

Mass masonry at Gatun and Miraflores Locks was completed in the latter part of May, 1913, and at Pedro Miguel Lock, several months earlier.

The work at Gatun since September 1, 1912, as summarized in The Canal Record, has comprised building the lower wing and approach walls, and completing the upper approach wall, which was within three per cent. of completion a year ago.

At Pedro Miguel, during the same period the approach and wing walls at the upper end and the east wing wall at the lower end, were built, and the lower approach wall was extended about 300 feet.

At Miraflores, the lower lock, which was about half done on September 1, 1912, was brought to completion, and the wing and approach walls at both entrances were begun and completed.

Recent and future concrete work at the locks embraces a multitude of relatively small finishing operations around machinery and tracks, etc. Portable mixers are being used in the remaining construction. All of the large mixing and placing plants have been closed and are being dismantled.

Lock Gates.—Over half of the material in the lock gates was erected during the past 12 months. On September 1, 1912, the total quantity erected at all locks was 24,787 tons, or 42 per cent. of the required 58,000 tons; to-day, the lack of completeness of erection is designated by fractions of one per cent. Since September 20, the gates of the west flight at Gatun, and the east flight at Pedro Miguel, have been ready for the passage of vessels, and the west flight at Miraflores Locks was practically completed by the end of the month. All gates at Gatun and Pedro Miguel are to be mechanically completed by January 1, and at Miraflores by March 1, 1914.

Gate works at the locks began on March 21, 1911, in preparing the bearings for the upper guard gates at Gatun. The erection of these leaves began on May 17, 1911, and they were the first to be swung closed. This occurred on August 4, 1912, and the footwalk over them was completed in September, 1912. A year ago, all the leaves in the upper and intermediate levels at Gatun had been erected to full height, and work had just begun on the safety gates in the lower level and the lower guard gates. The first girders for these eight leaves were placed on August 29, 30 and 31, 1912; the lower guard gates were closed, and sea water admitted against them, on June 14, 1913. On September 1, 1913, erection, reaming, and riveting for the gates of Gatun Locks were all within less than one-half of one per cent. of completion.

At Pedro Miguel, gate work began at the upper guard gates, on August 7, 1911. On September 1, 1912, these gates had just been closed, the skeletons of all leaves were at full height, and those in the upper level had been sheathed. To-day, erection and reaming for all gates are within one per cent. of completion, and the finishing work is over 80 per cent. completed.

At Miraflores Locks, work on the gates began first on the upper guard gates and the safety gates of the upper level, in August, 1912. The upper guard gates were closed about the middle of June, 1913, and the lower guard gates on August 20, 1913. At present, all 28 leaves have been erected to full height, reaming is 98.5 per cent. completed, riveting, 90 per cent., and finishing, about 65 per cent. completed.

Emergency Dams.—The emergency dams are to be held in reserve for exigencies if the lock gates should get beyond control and allow a rush of water through the flight. The floating caisson dams are for use only when the water is under control, and are not attached to the lock structures; the first of these is now under fabrication at the Union Iron Works at San Francisco, and will be towed to the Isthmus when completed.

The placing of steel in the emergency dams began in August, 1912, with the laying of the circular track and pivotal base for the east dam at Gatun. Erection of superstructure proceeded directly thereafter and the dam was completed, except for final painting, in May, 1913. The contractor, the United States Steel Products Company, began the final operating tests on May 20, under supervision of testing engineers of the Canal Commission. Erection of the west dam at Gatun began about the middle of November, 1912, and tests were completed on August 15, 1913. This dam was swung across the chamber, and its wickets and gates dropped into place, in 35 minutes. Trained operators will be able to do this in 30 minutes, or less.

At Pedro Miguel, erection of the west dam was undertaken first, beginning on February 1, 1913. This structure was first swung across the approach chamber on September 2, and is now under test. Erection of the east dam, which began on April 1, is about 98 per cent. completed, and the structure will be ready for testing by the time the tests on the west dam are completed.

The Miraflores east dam erection began on June 1, and that for the west dam on July 1. All material for all of the dams, weighing a total of 13,400 tons, had arrived on the Isthmus by August 1, and erection was 80 per cent. completed on September 1, being practically confined to the two dams at Miraflores. These are slightly lighter than those at Gatun and Pedro Miguel, because of the lower head of water against which they will be used; each of them weighs approximately, 1,987 tons, as compared with 2,305 tons at Pedro Miguel and Gatun Locks. The east dam at Miraflores will be finished the latter part of October, and the west dam in November.

Operating Machinery.—In addition to the masonry, gates, and emergency dams there is a great amount of auxiliary machinery contained within the machinery rooms and operating galleries of the walls or in the culverts. This apparatus embraces the rising stem gate valves, which control the flow of water in the 18-foot culverts at the bottoms of the side and centre walls; the cylindrical valves, controlling the 6-foot culverts which run laterally from the wall culverts and pass water to the lock chambers, through the floors; the auxiliary culvert valve machines, which control the flow through a short auxiliary culvert designed to maintain the water at the same elevation on both sides of the upper guard gates; the guard valves and machines, controlling the intake of water into the side wall culverts at the upper end of the locks; the miter gate moving machines, to swing the leaves of the gates; the miter forcing machines, to draw the leaves tightly together when closed, and prevent leakage; the mechanisms which cause the handrails on top of the leaves to fold down when the leaves are swung back into their recesses in the walls; the pumps for unwatering sumps in the miter gate leaves, and in the pits

of the fender chain machinery rooms; the machinery for actuating the fender chains, at all upper and lower guard gates, and at the intermediate and safety gates in Pedro Miguel Lock and upper chambers of Gatun and Miraflores Locks; the tracks and conductors for the towing locomotives; and the posts for the illumination of the locks.

Ancillary to the foregoing is an elaborate system of electrical generation and transmission to the transformer rooms in the lock walls, from which power is distributed to the various motors, and the interior and exterior lights. The opening motors number 334 at Gatun Locks, 206 at Pedro Miguel, and 252 at Miraflores; and at each set of locks their operation will be managed from a central control house.

All of this work, as well as the installation of operating machinery in the spillways for Gatun and Miraflores Lakes, controlling 22 "Stoney" gates, each 47 feet long by 19 feet high, has been carried on by the erection subdivision of the First Division of the Office of the Chief Engineer.

SANITARY SURVEY OF RIVERS.

By R. O. Wynne-Roberts,
Consulting Engineer, Regina.

A BULLETIN of the Illinois State Laboratory of Natural History, published last June, comprises an article by Mr. Stephen A. Forbes, Ph.D. LL.D., and Mr. R. E. Richardson, A.M., which is a compilation of scientific information on the biological and chemical analyses of the Illinois River. It is well known that Chicago constructed a huge drainage canal at a cost of $50,000,000, including power-plant, to dispose of its sewage by dilution. This sewage discharges into the river near Lockport.

The article is comprehensive, covering over one hundred pages, and the reader who desires details that are not contained in the following review is advised to obtain a copy of the bulletin. As much attention is now being paid to the purification of rivers, the writer has deemed it of interest, and perhaps of service, to review the work done by the authors of the article, which is largely referred to, in the following paragraphs, by extracts and references:—

"The Illinois River is peculiarly characteristic of the State of Illinois, and, next to the prairies, is its leading natural feature. The level richness of the central plateau of the State is reflected in the turbid waters and the broad, sluggish current of the stream; and its wide bottom-lands, originally covered with huge trees, completely flooded when the river is highest, and holding many marshes and shallow lakes at its lowest stages, are a relic of the time, not so very far remote, when the limpid waters of the Great Lakes rolled down its valley in a mighty flood on their course to the southern gulf. It was not an accident that this river was the first great artery of transportation into and through the State, or that the first colonial settlement and the first fortified post in Illinois were established on its banks. After the railroads had deprived it of its commerce it was discredited and neglected for many years, and the second city in the country and the second city in the State have long used it as a mere convenience for the discharge of their organic wastes.

"These are temporary conditions, however, and the time seems now at hand when the people of Illinois will learn to appreciate and develop this great gift of nature in the various directions in which it may be made to serve their interests and their pleasures. Its frequently beautiful and occasionally picturesque scenery is attracting more attention every year; and when, as is sure to happen in due time, a superior highway follows its course between Chicago and St. Louis; when the attractive building sites on its banks are relieved, as they now might generally be, from the midsummer plague of mosquitoes; when its most interesting situations are converted into parks, and its fisheries are protected and enriched by means of State reservations for the breeding and feeding of fishes; and when, as must eventually come to pass, it becomes once more an indispensable central link in a principal line of traffic between the Great Lakes and the Gulf, it will take for all time, for the State at large, the place which Lake Michigan now holds for our greatest city.

"The senior author of this work began work as a biologist, on Illinois River problems, some thirty-six years ago; and the junior author has virtually lived on the river for purposes of investigation during the last four years. The Natural History Survey of the States has published in the meantime more than 2,500 pages of contributions to its biology; and it is now rounding this work to a close, and bringing its results to bear, in practical ways, upon the economic problems most pressing and important at the present time.

"**Objects of the Investigation.**—The Illinois River work of the Natural History Survey, pursued at irregular intervals since 1877, became virtually continuous at Havana for five years, from April, 1894, to March, 1899, after which it seemed expedient first to diminish, and in 1903 to suspend, field operations in order that more important scientific results might be organized, reported, and published.

"The opening of the Chicago Drainage Canal in 1900 was a revolutionary event in the biological history of the river; and, as the most important period of our earlier work was that immediately preceding this event, an examination of its consequences to the general system of aquatic plant and animal life was an important part of our object in recommencing systematic study. As the Illinois is a rather peculiar member of the great Mississippi River system, it was also much to be desired that comparative studies should be made on the life of the more closely related companion streams; and, as the Illinois is economically one of the most productive rivers in the United States, it was evidently time to study the subject of the conservation and possible increase of its values in the light of the knowledge we had gained, and intended to gain, of its physical, chemical and biological conditions and requirements.

"The reports of the work of the earlier period were largely on the minute plant and animal life of the stream —its so-called plankton—which forms a considerable part of the food of many kinds of fishes, and nearly all the food of the young of almost every kind; and the plankton product of the waters of the Illinois under the new conditions, as compared with those prevailing before the opening of the sanitary canal, was one of the first topics to commend itself to us for careful study. Involved in this subject of food production for fishes, river mussels, and other useful aquatic animals, was the economic effect of a great increase in the flow of the stream, the rise in its levels, and the consequent expansion and longer continuance of its overflows, which, there was reason to suppose, might so increase the food supply and enlarge the breeding and feeding grounds of fishes as to increase the fisheries products of the stream. It was also a matter

of interest and importance to learn the effects, both direct and indirect, of the increased inflow of sewage by way of the sanitary canal and the Des Plaines, upon the fishes and mollusks of the waters of the stream and systematic collections from it at various points on its course, under various conditions and at different times of the year."

The investigations of special interest to municipal engineers are those commenced in 1911, when chemical determinations and biological collections for an analysis of seasonal conditions on the upper Illinois and in related waters, were begun July 18th, and repeated at frequent intervals until Dec. 13th. Similar trips were made in Feb. and Mar., 1912, for a study of winter conditions; and in July, 1912, an elaborate series of oxygen determinations was made for the entire length of the river. Aug. 21st to Oct. 12th two such series were obtained for the upper Illinois; and in Nov. two more, for the whole system, with comparative tests for the Mississippi, below and above the mouth of the Illinois. The situations thus brought more or less closely into comparison were the sanitary canal at Lockport, the Des Plaines River at the same place and at its mouth (Dresden Heights), the Kankakee, just above its mouth, and the Illinois River at Dresden Heights, Morris, Marseilles (both above and below the dam which crosses the river there), Ottawa, Starved Rock, Peru, Hennipin, and Chillicothe. The distances of these points from the mouth of the Chicago River are approximately as follows, in miles: Lockport, 35; Dresden Heights, 53; Morris, 62; Marseilles, 80; Ottawa, 86; Starved Rock, 95; Peru, 102; Hennepin, 116; and Chillicothe, 145, ninety-two miles of this last-mentioned distance being on the Illinois River itself.

"Finally, in Mar., 1913, samples of the bottom sediments were collected from all the five Illinois River dams, and from some other points in the main channel, for physical and chemical examination, with a view to ascertaining the condition of the river bottom when the river water has been for some months at or near the freezing point."

Messrs. Forbes and Richardson, for reasons stated, take the years 1897-8 and 1909-10 as the basis of comparison of the plankton production and quality of the waters. The above years are before and after the opening of the Drainage Canal, and, as in the former year the plankton was 3 c.c. per cubic metre of water and in the latter 5.07, "we have sufficient reason for concluding that the plankton production of the stream has been largely increased per unit of volume as a consequence of the opening of the drainage canal, and that, so far as the evidence goes, the ratio of the present yield to the former is at least as 5 to 3. Remembering, further, that the most important plankton product is that of the spring months, when the young fishes are hatching from the egg and are dependent upon the plankton organisms for their earlier growth as fry, we find a special significance in the fact that the plankton yield of the river for the months of March, April, May and June was 2.85 times as great in 1910 as it was in 1898.

"If to these facts concerning the increase, in recent years, in the percentage of plankton contained in the waters of the Illinois, we add those concerning an increase in the average volume and area of the waters themselves, we shall see that their total plankton must have been many times multiplied, and that the fisheries of the stream should feel the effects of this greater abundance of this important element of fish food.

"The importance of an abundance of organic matter in the water as a means of producing a rich plankton is, in fact, so well known that growers of pond fishes in Europe deliberately manure their ponds to increase the supply of food for their fish; and there is considerable evidence, also, that the plankton of the Elbe is largely increased by the sewage of Hamburg and Altona poured directly into that stream."

The Des Plaines River near Lockport in Sept., 1911, was heavily loaded with sewage wastes, and septic organisms were at the maximum. "The most conspicuous of these was the well-known fungo-bacterium, *Sphœrotilus natans*, a filamentous form, which grows in long, loose, hanging tufts and branches in septic and polluted waters. The stony bottom of the Des Plaines, between Lockport and Dresden Heights, was carpeted with this plant, and with it were associated a considerable variety of *Protozoa*, all characteristic foul-water species."

Sir Rupert Boyees, F.R.S., the eminent English biologist and analyst, when giving evidence at the High Courts of Justice of England in an important Welsh river pollution case, stated that there are two kinds of sewage fungus—*Sphœrotilus* and *Leptomitus*. The first was probably known by the obsolete name of Beggoatoa Alba. It is like flock or cotton fluff, and flows in the water near the surface. It usually sticks to twigs in preference to stones and gravel, and the information given by Messrs. Forbes and Richardson is interesting in this respect.

The authors next describe the condition of the Illinois from Dresden Heights to Marseilles. "In July, 1911, it was in an especially saprobic or septic condition, culminating at Morris, if we may judge by the number of septic organisms in the plankton." "The most abundant of these were Sphœrotilus natans, detached filaments of which made about 90 per cent. of the number of the plankton organisms in this and the following section." "Flagellate, colorless Protozoa, which feed upon bacteria, were also extremely abundant in this section. The largest number of *Oikomonas termo*—a bacterium-eating protozoa—were found at Marseilles above the dam."

"In the Starved-Rock-Chillicothe section of the river the outstanding feature of the plankton was the marked increase in diatoms and other chlorophyll-bearing unicellular organisms, plant and animal, which became sufficiently abundant by the time Hennepin was reached to give the water a characteristic greenish tinge. This greening up of the water below La Salle was noticed, in fact, on a down-stream trip in June, 1910, and was conspicuous to the naked eye in both 1911 and 1912, most noticeably so at lowest water levels."

The dissolving oxygen of the water in the sanitary canal at Lockport ranged from 0.4 of one part per million on Nov. 1st, 1912, to 9.3 parts per million on Feb. 17th, 1912. As temperature has an influence on oxygen-dissolving capacity of waters, the above figures require to be reduced to the percentage of saturation at the temperature observed at the time when the test was made. Consequently, the first was equal to 3.5 per cent. of oxygen saturation and the latter equal to 64.9 per cent.; the average of six observations made was 4 parts per million, or 31.9 per cent. of saturation. Fish were found, but these were either dying or dead, overpowered by the toxic contents of the stream. There were no signs of animal life, and the only insects seen in or on the water were a back-swimmer (*notonecta*) and several water-boatmen (*corixa*), both of which, as they breathe air, can afford to be indifferent to the deficiency of oxygen.

(To be continued.)

The Canadian Engineer

ESTABLISHED 1893.

ISSUED WEEKLY in the interests of CIVIL, MECHANICAL, STRUCTURAL, ELECTRICAL, RAILROAD, MINING, MUNICIPAL, HYDRAULIC, HIGHWAY AND CONSULTING ENGINEERS, SURVEYORS, WATERWORKS SUPERINTENDENTS AND ENGINEERING-CONTRACTORS.

Present Terms of Subscription, payable in advance.

Postpaid to any address in the Postal Union:

INTERNATIONAL HIGHWAYS.

It is to be hoped that Deputy Minister Campbell will be successful in his efforts to persuade Premier Borden to appoint a commission to co-operate with the Joint Congressional Committee on Road Legislation of the United States. Such an international body could do a vast amount of good work in reaching a sound understanding that would make many great international highways possible in the future. It would be highly advantageous to have equitable, uniform road legislation in all the Provinces of Canada and the States along the Canadian border. Road construction could be correlated so that the important roads of each Province would connect with the important roads of the other Provinces and of the adjoining States. This would greatly promote the trade and friendly relations between the two countries. The commission might also consider allowing United States autoists to tour Canada with the minimum of trouble and expense at the border. It is for the benefit of the Dominion to make the roads as inviting and pleasant as possible to United States autoists. The tourists are frequently capitalists, and a better knowledge of Canada would cause many of them to invest more money here.

MATHEMATICS AS AN ENGINEERING STUDY.

The value of a thorough study of mathematics in engineering training is a much-discussed topic. An engineer does not advance far into his profession before he contracts the thought and dwells reflectively upon it.

No science is so intimately connected with engineering as mathematics. Arithmetic, geometry, algebra and trigonometry are regularly employed, while an amalgamation of the science with physics has produced the derivation of stresses, moments, radii of gyration, energy, etc., that form the daily food for engineering thought and accomplishment. Yet, of the science of mathematics the average engineer has forgotten, five years after he graduates, fully two-thirds of the amount he had, at one time, carefully mastered; and when one reviews its scope he is surprised to find the infrequent applications of its higher attainments. It will be noted that the calculus is used comparatively seldom, and a text on analytical geometry finds little entertainment in the routine practice of an engineer. This is apparently as it should be, though, and memory need not be brought to task to have the old and intricate pathways repaved.

Yet the student struggle in the mathematical gymnasium goes on apace, and the study forms the chief channel for his intellectual development. It is, therefore, timely to acquaint those of our readers who are preparing for entrance into the profession, with the necessity of such devoted attention to a study, much of which will later be forgotten.

This is best answered by suggesting to the student of engineering that, when he becomes a graduate, he will take time to reflect upon the mental training derived from it, which is the sum of the necessity for a considerable part of the study. Again, like many commodities that might be mentioned, he will find that when he needs its application he needs it badly. Herein lies a vital point. Though an engineer, eminently successful, may have forgotten everything but the bare principles, a clear

knowledge of how to apply them to his work spells its importance to him.

The young engineer must remember that engineering is not merely the getting and holding of jobs, or the handling of a big contract. There is the *science* as well as the *practice* of engineering, and experience shows that the men who have played a prominent part in the development of both have seldom been those who have had an aversion to mathematics.

While there is an excuse for the scarcity of purely mathematical treatises in an engineer's library, in that mathematics is a member of the family of "pure" sciences, it is not to be inferred by the young engineering student that the owner has not still a working acquaintance with the principles, at least, of the science.

CONCRETE CONSTRUCTION.

In every line of construction in which Portland cement has been used, the first objection raised by the layman has been that such skilled construction methods are necessary that frequent failures are likely. Because concrete looks so unstable when first poured, and takes years to reach its height of perfection, it is likely to be condemned even by city commissioners. So, it is not surprising to find many officials vigorously opposing concrete roads because "it requires such a lot of care and watching to get them laid right."

But are faulty construction methods or dishonest contracting any more fatal to concrete roads than to roads of any other type? We hold no brief for concrete roads. As a matter of fact, we believe they will have their limitations of usefulness, just as have macadam and brick. But some of the concrete roads that have been built are so excellent that concrete—properly constructed—must be given place as a paving material worthy of consideration along with other materials. It must not be tabooed merely on account of poor contracting being likely to ruin the road.

Dishonest, careless or incompetent construction can as readily spoil sheet asphalt, brick, bituminous macadam or other pavements, as it can concrete.

EDITORIAL COMMENT.

Dr. J. A. Amyot and Mr. F. A. Dallyn, C.E., water bacteriologist and chief engineer, respectively, of the Provincial Board of Health, have reported as follows concerning the Thirty-One Mile and Pemichangaw Lakes scheme of water supply for the city of Ottawa. (See *The Canadian Engineer*, Oct. 16th, p. 595):

"Investigation of the waters and catchment basin of the proposed water supply for Ottawa at Thirty-one Mile and Pemichangaw Lakes, together with the perusal of the report of Sir Alexander Binnie, convinces us of the feasibility and value of the scheme. We have no hesitation in recommending its approval by the provincial board in preference to any other source and supply heretofore proposed."

* * * *

A couple of weeks ago our esteemed contemporary, "Canadian Machinery," published a proposed design for a new Machinery Hall at the Canadian National Exhibition. The idea is excellent. There certainly should be a new machinery building. The reproduction of the suggested design in our columns is unnecessary, as it is entirely unofficial, but we desire to support heartily the general scheme.

The plan offered by Mr. Hare in "Canadian Machinery" may possibly meet the needs of the machinery firms, but the Exhibition's architects will likely further improve upon it. We would suggest to the Exhibition Board that, when the design of the building is under contemplation, they consult a score or more of the leading machinery manufacturers and obtain their views of their own requirements.

LETTER TO THE EDITOR.

Electrification of the Canadian Northern Tunnel.

Sir,—In your issue of October 9th, you say, on page 571: "Of all the great railway systems of the world using electricity for the operation of their terminals, there is not one which has not adopted this system only after previously using steam. The Canadian Northern terminal in Montreal, therefore, will be the first to be operated entirely by electricity from the commencement. No steam locomotive-drawn trains will enter the tunnel. Specially constructed electric locomotives will be exchanged for the steam engines at the Back River yards."

A few days ago some local newspapers, commenting on the contract awarded to the Canadian General Electric Company for the electrification of the Canadian Northern terminal in Montreal, also stated that this would establish a record, being the first time any railway terminal would be operated by electricity from the beginning. This, of course, is quite wrong, as it is exactly what was done on the Pennsylvania Railroad when, in 1901, it decided to bring its trains to New York, exchanging steam engines for electric locomotives at Newark, some 12 miles away. Aside from the construction and electrification of a new line and of subaqueous and land tunnels it included the construction of a new terminal which, of course, was operated entirely by electricity, as it should be, from the commencement in January, 1910.

Long before this, however, the same had been done in Paris. The Orleans Railway Company decided in 1897 to extend its lines 2.5 miles from the Austerlitz station to a better and more central location in the city of Paris, to its present terminal called the Quai d'Orsay station. This involved the construction of 2.5 miles of tunnels and of a new terminal which were operated by electricity from the beginning of operations in 1899.

Far from changing from steam to electricity, these improvements were designed for electric operation and nothing else.

Mr. A. J. Cassatt, President of the Pennsylvania Railroad, when in Paris in 1900 was so well impressed with the electrical operation of the Quai d'Orsay station and of the practicability of exchanging locomotives on the outskirts of the city to bring the trains in a new terminal that he began at once to orient the policies of the Pennsylvania in that direction.

Many books and technical papers have described these undertakings which it is needless to enumerate in detail. I might, however, mention among them Revue Générale des Chemins de fer et des Tramways, Nos. of February and November, 1898, and of May and July, 1901; and Transactions American Society of Civil Engineers, Volume XLI., LXVIII. and LXIX.

Yours very truly,

PAUL SEUROT.

Montreal, October 13th, 1913.

A DEPARTURE FROM COMMON PRACTICE IN SEWAGE DISPOSAL.*

By Alexander Potter, C.E.,
Consulting Engineer, New York City.

THE city of Springfield, Mo., is located two hundred and forty miles southwest of St. Louis, among the foothills of the Ozark mountains, 1,400 feet above sea level. During the last decade the growth of the city has been very rapid. The population in 1900 was 23,000 and in 1910 it was 34,000. The present estimate is placed at 46,000. The area of the city is fourteen square miles.

The built-up part of the town is sewered and recently sewer extensions have been built into the fast growing outlying districts of the city. Up to the present time over 105 miles of public sewers have been completed.

A ridge running east and west divides the city into two distinct drainage areas, known as the northern and the southern areas. The northern area, which is the smaller of the two, takes in about two square miles and is drained by a number of small streams which discharge into the Sac River. The southern area takes in all of the thickly populated districts, including the new addition south of the city, and drains southwesterly into Jordan and Wilson creeks, tributaries of the James River.

Necessity of Sewage Disposal.—During the greater portion of the year the natural flow of all the streams is so small that they are unable to assimilate the large quantities of sewage that are constantly discharged into them. In the spring of 1911 the nuisance from raw sewage discharged into these streams became so serious that the city authorities realized that unless immediate steps were taken to abate this nuisance the city would make itself liable for damages.

Before calling in an engineer to design the much-needed improvements to the sewerage system, the city appropriated $100,000 to construct sewage treatment plants at two sewer outlets. After appropriating this money the city proceeded to call for bids upon contractors' plans and specifications. This plan was abandoned, however, before the contract was let, and the city retained the writer to design and supervise the necessary sewage disposal plants.

Outline of Improvements.—The ridge extending east and west through the city made it necessary to construct two sewage disposal plants. The most logical location for the sewage disposal plant for the northern district was near Doling Park, directly north of the city limits at the mouth of the existing sewer. In the southern district the ordinance called for the construction of a sewage disposal plant at the mouth of the main outlet sewer. To construct a sewage disposal plant at this point was not recommended. The site is low, subject to inundation, and pumping would have been necessary.

On account of the small quantity of water flowing in Wilson and Jordan creeks during the greater portion of the year, the treatment of the sewage in settling tanks alone would not give a sufficiently pure effluent to abate the nuisance. Some additional treatment, such as contact beds or intermittent filters, was therefore absolutely necessary. To obtain a head at the southern outlet sufficient to operate a filter would back up the sewage in the main outfall sewer for a distance of at least 3,500 feet. This sewer, which is an egg-shaped brick sewer, 28 inches x 42 inches, was not strong enough to withstand any internal hydrostatic pressure without rebuilding. Above its mouth the outlet sewer for a distance of 3,200 feet has a fall of only 4.0 feet; at this point there is a two-foot drop and the grade increases to 4.1 feet per thousand. It was recommended that the treatment plant be built at the point where this change in grade occurs. To obtain at this point the necessary head to operate the plant only 2,000 feet of sewer would be surcharged. For a distance of 1,436 feet, that portion of the length where the hydraulic gradient falls above the natural surface of the ground, the existing egg-shaped brick sewer was replaced with 36-inch reinforced concrete pipe of the Meriwether type, designed to resist this pressure. This reinforced concrete pipe has been found very satisfactory

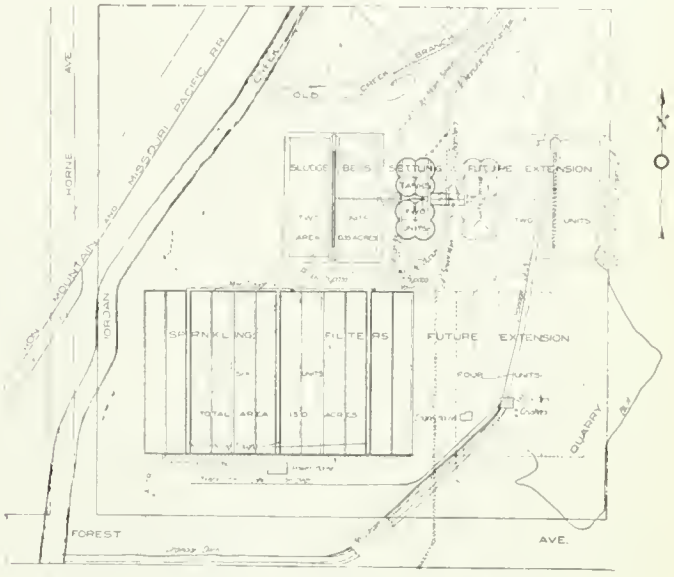

Fig. 1.—Location Plan of Southern Sewage Disposal Plant.

under the head to which it was subjected, viz., from 3 feet to 10 feet, and the line appears to be practically watertight. The existing sewer below the sewage disposal plant was not rebuilt and is used to convey the effluent from the plant to the outlet.

Type of Plant Recommended.—On account of the limited area available it was deemed advisable to use intermittent filters instead of contact beds. The ordinary type of sprinkling filter could not be used, as such a filter requires a head of at least five feet to operate the nozzles. Such a head could be obtained only by pumping. Mechanical distribution was therefore recommended. The distributor selected is operated with a head of only 12 inches.

Fig. 1 shows the general arrangement of the plant as built. It consists of a grit chamber built in duplicate, two settling tanks of the two-story type, a sprinkling filter divided into six units, each 53 feet 9 inches wide and 200 feet long, a sludge bed 0.35 acre in extent, and a final settling basin of 150,000 gallons capacity, located at the outlet, 3,600 feet from the remainder of the sewage disposal plant.

Grit Chamber.—The grit chamber is constructed in duplicate. The flow in the grit chamber is retarded sufficiently so as to retain only the suspended mineral solids

*To American Society of Municipal Improvements, 20th Annual Convention, Wilmington, Del., Oct. 7th to 10th, 1913.

which would interfere with the operation of the settling tanks. Provision is made so that during times of flood the back pressure on the outfall sewer can be readily and quickly relieved, thus scouring out whatever deposits may have formed in the 36-inch reinforced concrete pipe.

Settling Tanks.—Concrete, either plain or reinforced, is practically the only structural material available for constructing sewage settling tanks of the dimensions required for a large municipality. So far as the writer knows, the circular tank has been used in this country only in constructing the smaller units; for the larger sizes it has been customary to use rectangular construction. The rectangular form under all conditions, and especially when a large portion of the tank is above the surface of the ground, is a more expensive form to build. The Springfield sewage tanks are neither square nor truly circular. Each unit is four-leaf-clover shaped, consisting as it does of four semi-cylindrical segments 26 feet in diameter. This type of construction is peculiarly

done, and different stresses are used for the tie rods than are used for the shell, the shell, instead of being subjected to simple tension, will be subjected to bending. The tie rods are fastened to a steel plate 8 inches wide, ⅞-inch thick, bent to a 5-inch radius. By means of double nuts the reinforcement is kept in accurate alignment, which insures equal distribution of the tension among the larger number of tie rods.

The cylindrical segment must be free to expand in all directions. If the expansion is in any way prevented by interior construction, such as the troughs, false bottoms, beams, etc., the shell, instead of being under tension only as contemplated by the designer, will be subjected to heavy bending, often sufficient to cause the fracture of the structure. To permit of the free expansion of the shell when under internal pressure, all interior construction, except at the intersection of the ties and struts with the shell, is separated from the shell by expansion joints.

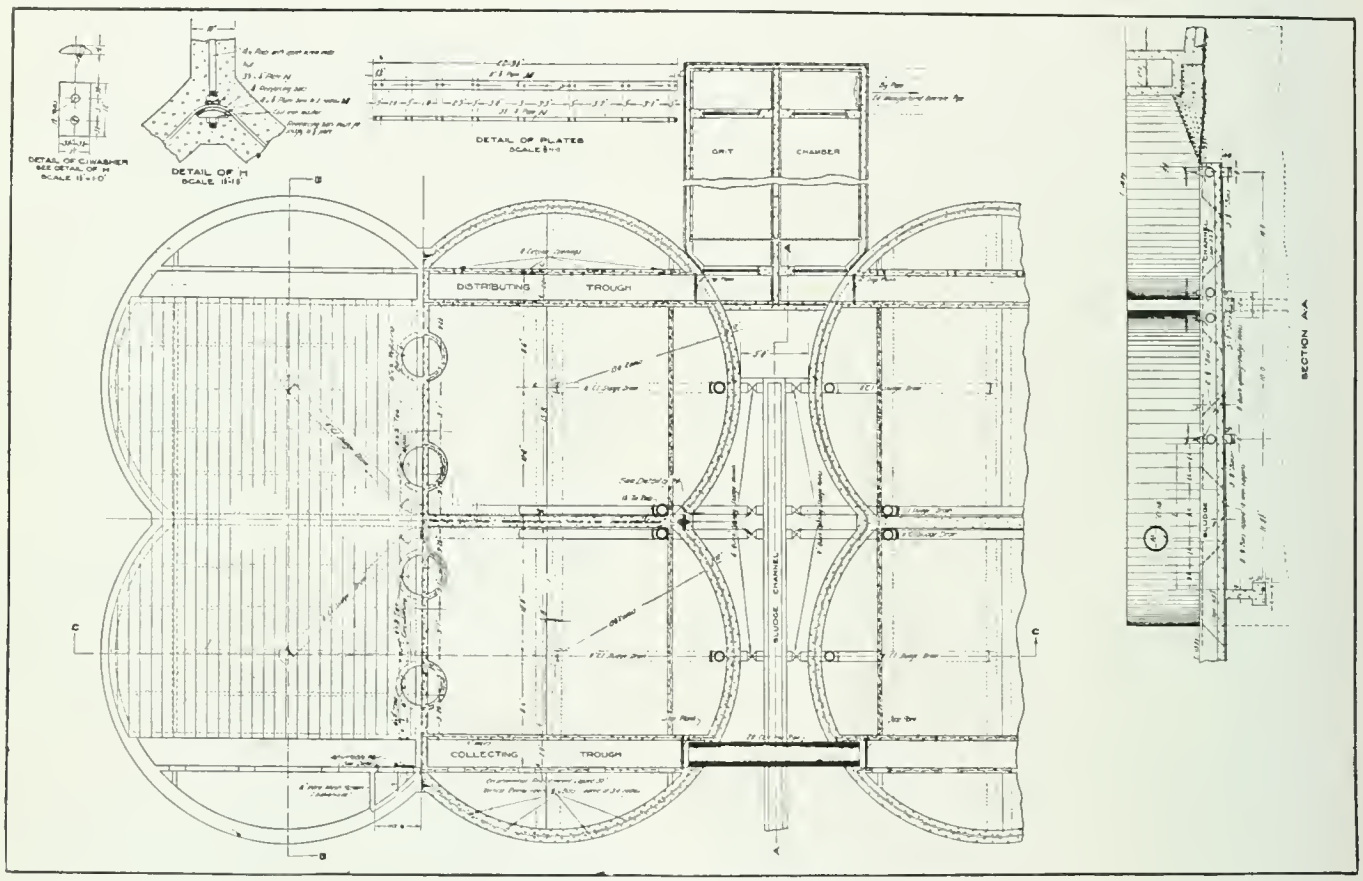

Fig. 2.—Plan and Details of Settling Basins.

well fitted not only to resist the water pressure from within, but also the earth pressure from without when the tank is below the ground and empty. The construction features of the tank are clearly shown in Figs. 2 and 3. The shell of the semi-circular segments is 12 inches thick, reinforced vertically with ¾-inch bars spaced 3 feet centres and circumferentially with ¾-inch square bars spaced so that the unit stress does not exceed 14,000 lbs. per square inch. The unbalanced tension at the point where the semi-circular segments intersect is taken up by 1¼-inch circular rods embedded in concrete struts, as show in detail H of Fig. 2.

The steel reinforcement in these ties is designed to to resist the tensile forces at the same unit stress as the circumferential reinforcement in the shell. If this is not

After passing through the grit chamber, the sewage enters the distributing trough, which is 2 feet wide, and holds, under normal conditions, about 2 feet of liquid. (See Fig. 3.) Eight 8-inch circular openings, placed in the sides of the trough near the bottom and on the side next the outer wall, admit the sewage to the settling compartment. At the end of the trough is an additional opening, placed so as to be but half submerged, so that whatever scum may tend to collect in the distributing troughs is carried over into the settling compartments. Each settling compartment has a capacity of 111,000 gallons, which gives an average period of retention of 1.4 hours when the plant is operated at 4,000,000 gallons, its capacity. The flow in the settling compartment is parallel to the direction of the slot. To prevent eddies

and other disturbances from being set up in the settling compartments which might interfere with the settling efficiency, the liquid is admitted to the settling compartment in a direction opposite to that which it must take in passing through the compartment. The clarified sewage leaves the settling compartment over eight 15-inch weirs discharging into the collecting trough.

The presence of the concrete struts in the settling compartment does not in any was interfere with the efficiency of the tank. Where necessary, they can be capped with wedge-shaped pieces of concrete having slopes of at least 45 degrees.

In that circular segmental area between the distributing trough and the shell of the tank, all of the floating matter is collected and forms a very heavy scum, requiring slight attention from the operator.

To increase the settling efficiency of tanks of the type described, the writer uses vertical circulation. The amount of sewage thus circulated is very small and does not exceed two per cent. of the total amount of the sewage treated. To accomplish the vertical circulation mentioned, a 6-inch cast iron main with four 4-inch circular openings is laid in the digesting chamber of each tank, about 6 feet above the slot. (See Figs. 2 and 3). This circulating main terminates in a small chamber located in the segment between the collecting trough and the shell, which chamber has an adjustable weir to control the flow from the digesting chamber into the collecting trough. In the Springfield plant the liquid thus drawn off is mixed with the effluent from the settling compartment and the resultant mixture is treated on the sprinkling filters. In other plants that the writer has built, the liquid drawn off from the digesting chambers is returned to the distributing troughs. Circulation such as that used in Springfield is especially of value when the sewage to be treated reaches the plant in a more or less septic condition. The plant has not been in operation long enough to determine the exact value of the circulation system.

Sludge Digesting Chamber.—The suspended organic and mineral matter which settles out of the sewage in the settling compartment, slides down the inclined plane through the 8-inch slots located in the bottom of the wedge-shaped settling compartments into the sludge digesting chamber. The sludge digesting chamber has a capacity of 150,000 gallons below the opening. The bottom of this compartment is formed by four cone-shaped depressions in which the decomposed sludge ultimately collects. To draw off the sludge, 8-inch cast iron sludge pipes extend down into these cone-shaped depressions, the sides of which slope at an angle of 30 degrees. The lower ends of these pipes terminate in bell-mouths supported on spiders. The sludge pipes are carried up inside of the tank to the top, giving ready access for cleaning. The sludge outlets, of which there are four for each unit, discharge under a 5-foot head into a reinforced concrete trough which conveys the sludge to the drying beds. The open channel used for conveying the sludge is preferable to the closed pipes generally used. In an open channel the sludge drawn off is at all times visible to the operator, and therefore the character of the sludge drawn off can be controlled far better than when a closed sludge conveyer is used. There is positively no odor during the operation of the sludge valves, either in the trough or upon the sludge beds.

The Springfield tanks have been found to be very economical in construction. Concrete and steel are used under ideal conditions to resist the pressures to which the tank is subjected. From the contractor's standpoint also the cost of constructing the tank is not excessive. To construct the conical bottoms of the digesting chamber a vertical pipe 2 inches in diameter was placed in the centre of each cone and firmly braced. From this pipe was suspended a wooden triangle adjusted at such an elevation that the hypotenuse described the interior surface of the cone when rotated about the pipe. The concrete was mixed rather dry and placed in 4-inch layers and tamped as much as it would stand, the last layer being carefully brought to a true line by the swinging template. A ½-inch coating of 1 to 2 mortar was applied to the interior of the cones to give them a smooth surface.

To construct the outside shell of the settling tank the contractor used wooden forms made in 5-foot sections 2 feet high. A complete set of inside and outside

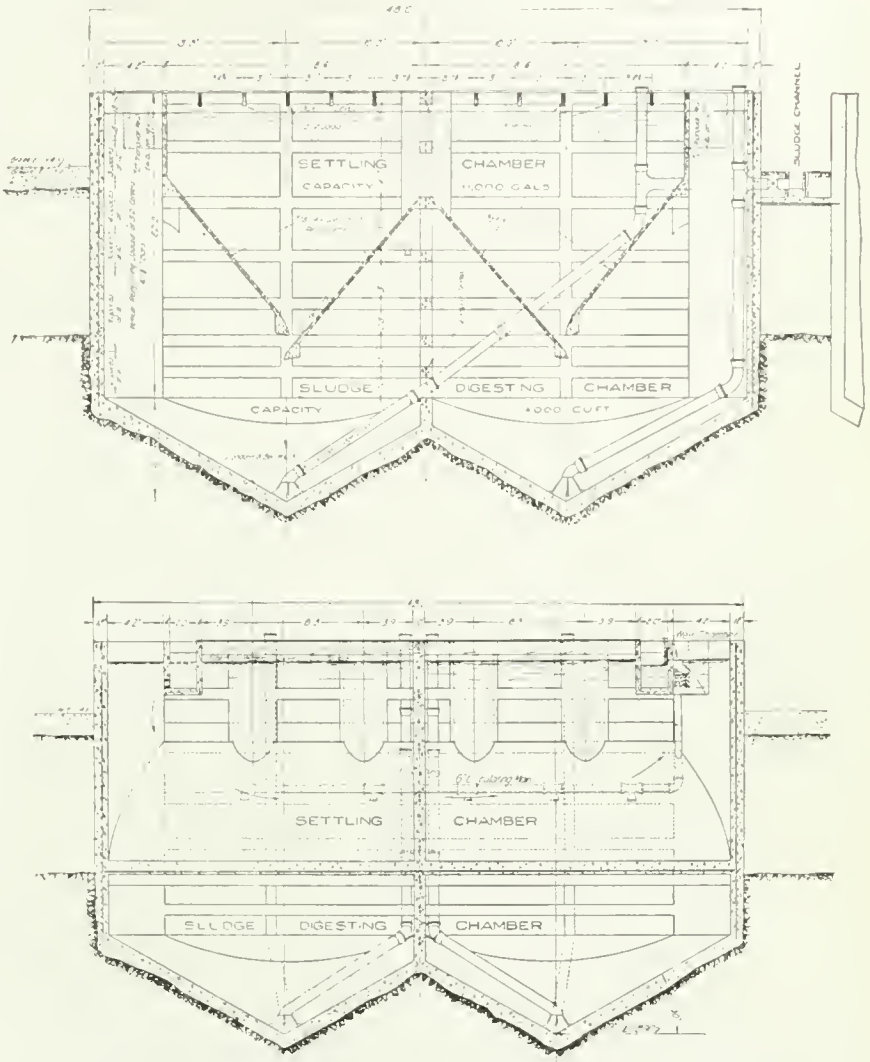

Fig. 3.—Detail Sections of Main Settling Tank.—Upper Section on CC., Lower Section on BB.

forms was built extending entirely around one tank, and a complete ring 2 feet high was poured at one time. The following day the sectional forms were raised 2 feet and wired in place at the new point. No trouble was found in shifting the forms and holding the walls plumb and true to line. The false bottoms of the settling compartments were built of No. 28—4-rib hyrib plastered with mortar to a thickness of 2½ inches. The circular ventilators also were built of hyrib and plastered with cement mortar, no other forms than templates being used.

Intermittent Filters.—To reduce the loss of head to a minimum power-driven mechanical distributors are used to distribute the sewage on the filters. There distributors were manufactured by the Ham Baker Company, of London, England. They are designed to distribute the sewage upon the beds with a loss of head, not to exceed 12 inches when the liquid is applied at the maximum rate of 720 gallons per square yard per day. Fig. 4 shows

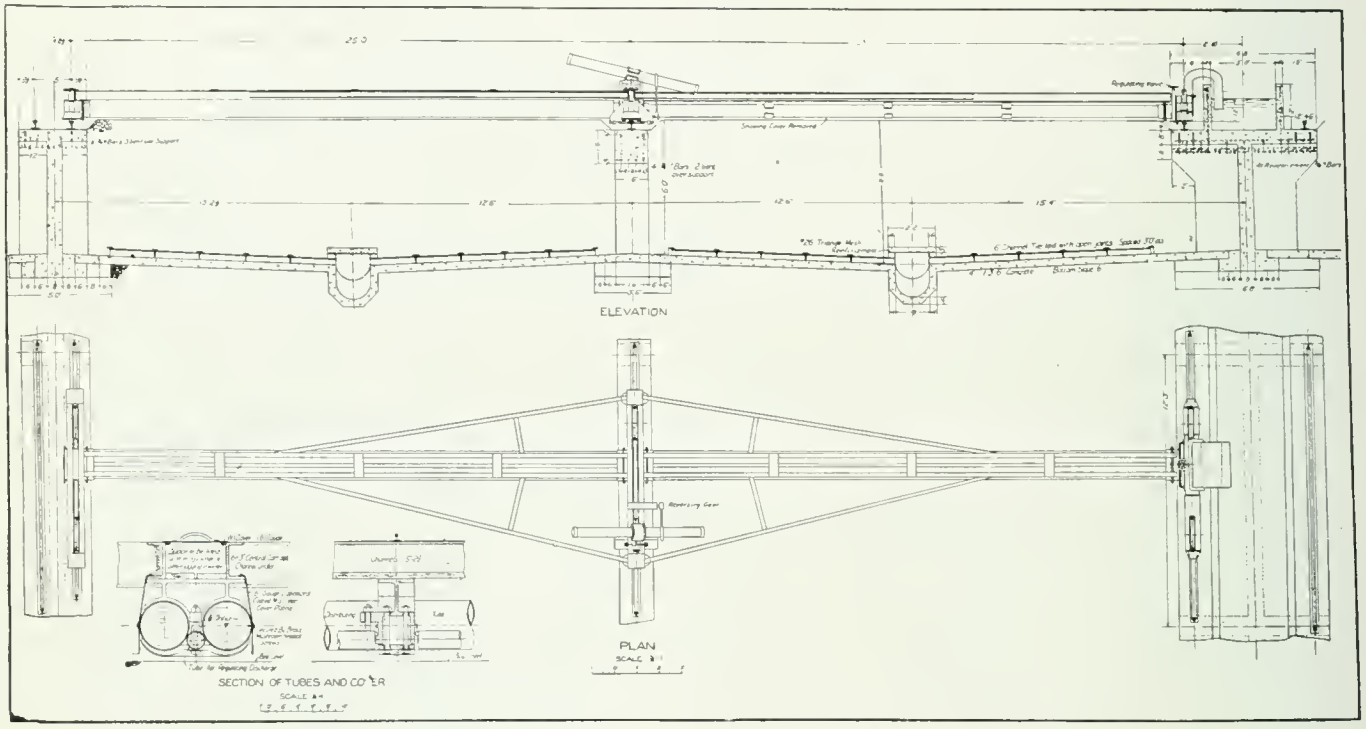

Fig. 4.—Section of Filter Unit Showing Traveling Distributor.

the construction of one of these distributors. Each distributor is supported on three rails, spaced 25 feet on centres. The length of the travel is 200 feet.

The effluent from the settling tanks is conveyed by a 24-inch reinforced concrete pipe to a main distributing trough located at the north end of the filters. The lateral distributing troughs which supply the traveling distributors are fed by 3-foot weirs from the main distributor. The object of these weirs is to insure a uniform distribution of liquid to the distributors. Fig. 4 also shows the construction of the sprinkling filters. The depth of the filtering material ranges from 6 feet 6 inches in the centre to 6 feet at the sides. The underdrains were not built as shown on the drawing. Instead of using 6-inch channel tile, the contractor was given permission to construct 6-inch semi-circular channels in the concrete floor and cover them with vitrified tile slabs. The main collectors are semi-circular in shape, 18 inches in diameter and of variable depth, the distance between them being about 25 feet. The rails on which the distributors travel are supported by concrete girders carried by piers spaced 12 feet, 5¼-inch centres. The area covered by each distributor is enclosed by an 8-inch concrete wall. The winter temperature of Springfield is sometimes so low that it may be questionable as to whether the traveling distributors can be successfully operated in extreme weather. Should the traveling distributors go out of commission or any of them break down, it is possible to utilize the filters or any unit thereof as a contact bed to be operated by hand, suitable gates being provided for this purpose.

Operation of Distributors.—Extending down the centre of the filters between two of the traveling distributors is a 3-foot rectangular conduit in which the normal depth of sewage is 16 inches. A cast iron siphon, 24 inches long and 8 inches in width, conveys the liquid from this trough to the distributor. This siphon is provided with a gunmetal air cock and brass air exhaust pump for starting the flow. The siphon discharges into the feed tubes, of which there are two. These feed tubes are made of wrought iron 3/16-inch thick and have an external diameter of 7⅜ inches. The feed tubes are supported at each end and at the centre by a cast iron carriage braced together by rolled steel beams so as to form a rigid structure. In each feed tube just above the centre are located ⅝ x 4-inch orifices, spaced about 15 inches lengthwise. The even distribution on to the beds is accomplished by a distributing tube 2½ inches in diameter, located between the feed tubes. This distributing tube is built in sections and can be raised or lowered as required to control the flow of sewage upon the beds. The feed tubes are protected with galvanized sheet iron covers provided with hinged access doors. The protection extends to within one inch of the surface of the bed in order to conserve the heat in the sewage as much as possible, especially during the cold weather. It also acts as a preventative of flies. A space is provided between the two channels supporting the feed tubes, which during the cold

weather is to be filled with moss, leaves or other insulating material.

Each pair of distributors is operated by an endless wire cable. All three sets of cables are driven by one 6-horse-power Otto gasoline engine, which gives the distributors a speed of 38 feet per minute. The change in direction of the distributors is accomplished by means of the reversing lever shown in Fig. 4.

The distributors have realized every expectation. Less than two horse-power is required to drive all six distributors. The writer believes that the distribution of the liquid over the bed is more uniform than can be obtained by the methods now in use in this country. The more uniformly the liquid is distributed upon a filter, the greater the quantity of sewage that can be applied to the filter to obtain the same degree of purification; or, with a given quantity of sewage, the more uniform the distribution, the greater the purification.

To the knowledge of the writer this is the first time that power-driven traveling distributors have been used in this country. The range of temperature at Springfield makes this installation an important one as indicating possible limitations of service in extreme winter weather without covering the filters.

Final Treatment of Filter Effluent.—The existing sewer conveys the filter effluent to the final settling basin located near the mouth of the existing sewer. This final settling basin is 150 feet long and 50 feet wide and has a capacity of 150,000 gallons. A reinforced concrete channel admits the sewage to the basin at the upper end and at the lower end a similar channel conveys the settled liquid through a short length of the existing sewer to the outlet into Wilson creek. It has not been deemed necessary to sterilize the effluent.

Sludge Disposal.—The sludge which is drawn off from the main settling tanks is conveyed by a concrete trough laid to a grade of 5/10 of 1 per cent. to the sludge beds. The sludge bed, which takes in an area of .35 of an acre, is divided by wooden partitions into twelve units, each unit being 25 feet wide and 50 feet long. Each sludge bed is underdrained with graded gravel 18 inches deep at the centre and 12 inches deep at the sides. Down the centre of each unit extends a 6-inch vitrified underdrain laid with open joints. The surface of the gravel is covered with a thin course of mortar sand to prevent the sludge from working its way into the gravel. The bed is given a slope of 1 inch in 10 feet away from the sludge inlet to assist in the distribution of the sludge over the entire bed.

The sewage disposal plant for the northern district, located near Doling Park, has a capacity of 500,000 gallons in 24 hours and, with the exception of the distribution of the sewage over the filter, is in all respects similar to the plant just described. Instead of mechanical distribution, nozzles are used to distribute the sewage over the beds.

The general movement towards the thorough and adequate equipment of Canada's great trade portals, Halifax, St. John, Quebec, Montreal, Vancouver and Victoria, as well as the development of harbors along the great lakes—such as, Toronto, Hamilton, Port Arthur and Fort William—is one which will, when completed, place our country in a position to compete effectively and successfully for its legitimate share of the world's trade.

A CANADIAN ELECTRIC STEEL FURNACE.

By T. R. London, B.A.Sc.,
James, Loudon and Hertzberg.

IN 1906 the Dominion Government issued the results of extensive investigations on the electric furnace iron and steel industry of Europe. Since the publishing of this report, which has been and still is a reference of great value, there has been very little evidence in Canada of commercial interest in electric smelting and refining, as far as the actual iron and steel industry has been concerned. Several electro metallurgical plants of great importance have grown up, but none of these has made any attempt to manufacture pig iron, or place steel products on the market on an extended scale. In 1911, the published results of the successful electro smelting of iron ores in Sweden added greatly to the hopes of those interested in electric metallurgy, as it was proven by these Swedish experiments that practical electro smelting was an accomplished fact, provided power and ore were sufficiently low. Canada was naturally looked to as a possible field for the new Swedish processes, as it is well known that Canadian

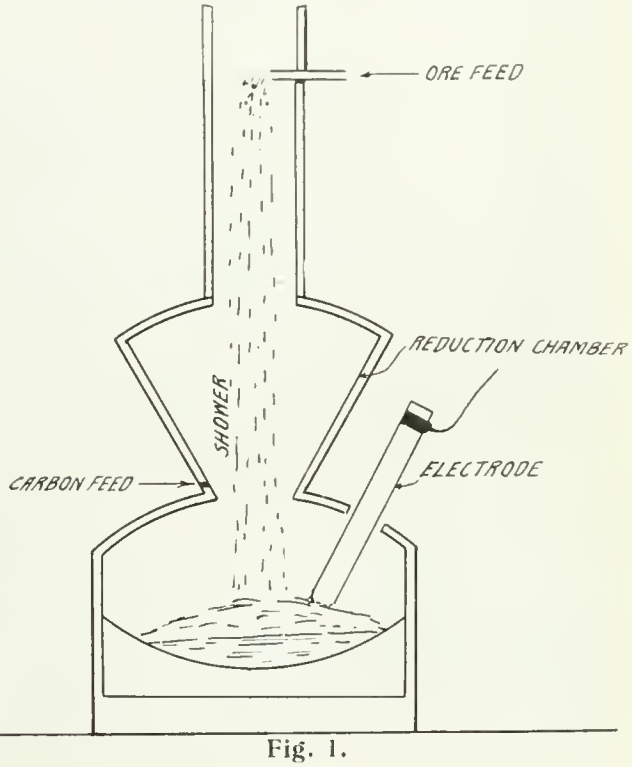

Fig. 1.

iron ores are not suitable for smelting in the ordinary blast furnace without concentrating and briquetting, but can be handled by electro-thermic method. In fact, the Dominion Government electric furnace experiments at Sault Ste. Marie were carried on with a view to making use of these ores. Interesting as the Swedish experiments were, nothing resulted commercially in Canada.

There are, of course, many economic reasons why the electric furnace has not been used in Canada in the steel industry; but, over and above these economic reasons, there exists one that is very largely responsible for the lack of advancement after the beginning made in 1906. This reason may be concisely stated by the well-known phrase, "lack of experience." These new processes required operators familiar with the actual run-

ning of electric iron and steel furnaces, and these men are few and far between. Lacking this experience, which, by the way, was confined to a few European countries, Canadian investigators have been working along their own lines, taking what could be gleaned at intervals from the little that is heard of other similar investigations in foreign parts.

In view of all this, it is particularly gratifying from every standpoint to note that an actual commercial electric steel plant has at last made its appearance in Canada. Quite recently an announcement was made of the incorporation of the Moffat-Irving Steel Works, Limited, having for its object the electro thermic reduction of iron ores and refining to steel.

Fig. 2.

The experiments of which this plant is the outcome have covered a period of some years, and have been of an extremely thorough nature. As intimated above, the difficulties met with in such work are of such a nature that those who persevere and overcome them deserve great credit.

The form of furnace finally adopted differs very slightly from the original design, the main differences being in details rather than principle. Fig. 1 is a diagramatic elevation of the furnace. The crucible is built on a substantial base of concrete. Above this hard-burnt red brick were used for a few courses, and finally, the silica brick forming the main body of the crucible were built up as represented in the cut (Fig. 2). The hearth is of rammed magnesite, giving a good basic bottom.

As indicated in Fig. 1, the ore particles are fed into the upper stack by a mechanical screw feed. The requisite limestone is also fed in at the same level. The carbon, in the form of finely ground coke, is fed into the crucible at the level indicated. The electrodes, three in number, for this furnace which operates on three-phase current, project into the crucible at an angle of about 60°. One of these electrodes is shown in Fig. 1. The remaining two are spaced at equal intervals around the furnace. In falling, the ore particles come in contact with a strongly reducing hot atmosphere of carbon monoxide gas and partial reduction takes place. The final reduction takes place in the crucible.

As would be gathered from the furnace having a basic hearth, the process as carried out is basic. It is well known that in the electric furnace it is possible to bring about a degree of refinement in the metal that is unattainable in the usual industrial processes. In fact, it is practically impossible, under ordinary conditions, to get the sulphur content of steel below a certain limit. Not that this limit leaves a bad steel, but, to get as far below as is possible in the electric furnace means a very high-grade metal. Another very distinct advantage claimed

for steel made under electro thermic conditions, is that it is possible to deoxidize the molten metal to a high degree of perfection. This has been entirely borne out in the work on this furnace. In fact, it was soon apparent in the early stages of the work that the solid condition of the steel, due to this absence of oxides, made the metal very desirable for steel castings. The steel resulting from

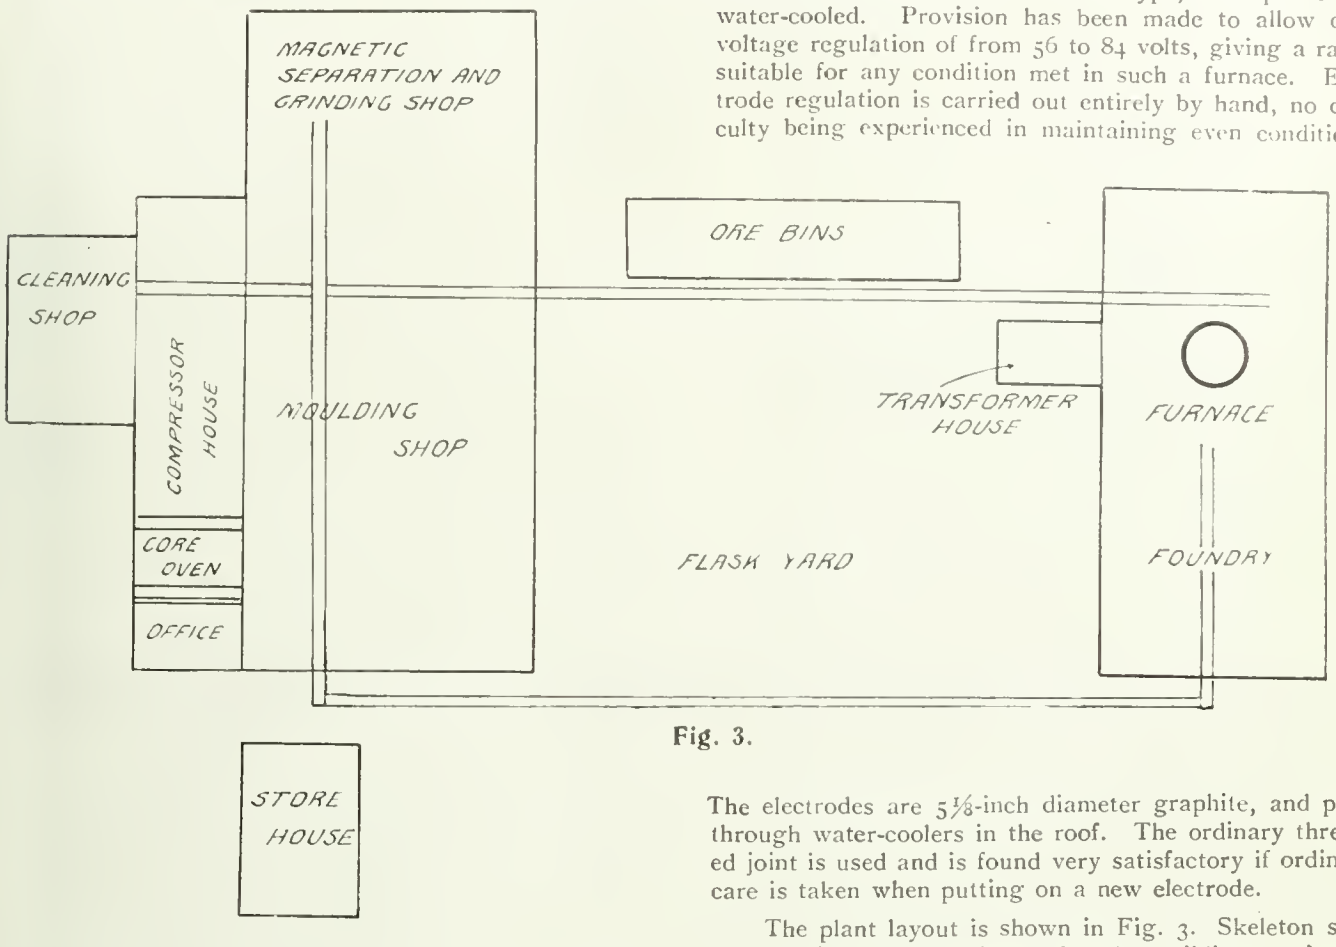

Fig. 3.

the process had very much the qualities of the best crucible steel, and physical tests show a tensile strength well above the average; but, this alone does not explain the wearing qualities of castings made from this steel. Indeed, it is only on the basis of the purity of the metal that any explanation of the quality can be made. So far no actual analyses for the presence of oxides and other injurious elements have been made, but the heat analyses for the ordinary elements looked for, show a high-grade metal. The following are some samples:—

C	Si	Mn.	P	S
.20	.30	.71	.03	.010
.30	.25	.78	.03	.010
.32	.25	.75	.035	.010

It is particularly noticeable that there is no difficulty in getting good metal heat after heat, due, of course, to the excellent control of temperature and slag conditions obtainable in the electric furnace.

The furnace, which was built to take 300 kw., is very seldom operated to full capacity, except at the end of a heat, so as to obtain a high temperature in the metal before tapping. A very complete system of oil burners has been installed for ladle heating which has proven to be an important item in the production of good castings. These ladles are of two-ton capacity, but are seldom called on to take off a heat of more than a ton at a time.

A great deal of care has also been spent in experimenting with various mixes of moulding sands, etc. The extremely high temperature attainable in the furnace gives a very fluid metal, suitable for the most intricate steel casting, but which requires facings and sands refractory enough to withstand being completely fused. Steel flasks made by bending channel iron are used entirely. The transformer is of the core type, three-phase and water-cooled. Provision has been made to allow of a voltage regulation of from 56 to 84 volts, giving a range suitable for any condition met in such a furnace. Electrode regulation is carried out entirely by hand, no difficulty being experienced in maintaining even conditions.

The electrodes are 5⅛-inch diameter graphite, and pass through water-coolers in the roof. The ordinary threaded joint is used and is found very satisfactory if ordinary care is taken when putting on a new electrode.

The plant layout is shown in Fig. 3. Skeleton steel construction was used in the foundry building, a view of

Fig. 4.

which is shown in Fig. 4. The stack B (Fig. 4) is for leading off the waste gases from the reduction chamber. The transformer house A (Fig. 4) is a separate unit containing all the instruments and the electrode control ap-

paratus. The moulding and cleaning shops are equipped with compressed air.

It is hoped to be able to give some more detailed results of the process in the near future. There is no doubt that the problem of handling Canadian ores has been solved in this process. The steel made in the furnace, as intimated above, supports all the predictions and published results up to the present as to the superiority of electro-thermic steel.

HIGHWAY ACCOUNTING, WITH SPECIAL REFERENCE TO MAINTENANCE.*

By Halbert P. Gillette, M. Am. Soc. C.E.

THE time is at hand when accounting and cost-keeping methods that have proved so effective in the management of private enterprises will also be universally applied to public works. There is fundamentally no economic difference between a road and a railway. Hence accounting methods that have been developed in the construction and operation of railways should prove efficacious in road construction and maintenance.

Every well-managed railway has an itemized plant or property account. How many ledgers relating to a system of highways will show the itemized investment in the entire mileage? Every well-managed railway has an itemized maintenance account that shows the monthly and annual maintenance expenses by divisions. Of how many road systems can the same be said? Every well-managed railway is careful to distinguish between expenditures that add to the investment in plant and expenditures that merely renew superseded and worn out parts of the plant. How many road ledgers show equal care in this vital matter? And it is vital, economically, not to confuse renewals with betterments; yet we all know of many recently published statements of road maintenance costs wherein more than half the cost was not maintenance at all.

When an old waterbound macadam is scarified and enough new metal added to bring it to its *original* thickness, the cost thereof is a maintenance expense. But if metal is added in amount sufficient to make the macadam 8 ins. thick where it was 6 ins. thick at the time of original construction, then the added 2 ins. is not a maintenance expense, but is an addition or betterment which should be charged to the property account. Even to a more marked degree is this true when a waterbound macadam is given a bituminous surfacing.

The editor of at least one prominent engineering periodical has recently written about the almost prohibitive cost of road maintenance, and has cautioned the public against bonding for road construction because of the short life of modern roads. This serious editorial error is the result of inadequate knowledge of proper accounting methods, for published road maintenance data are apt to deceive those who think that "maintenance" means what it should mean. As a matter of fact "maintenance, as commonly used to-day in reference to roads, means true maintenance and betterments combined, and is, therefore, a deceptive term.

Maintenance expense should never include anything else than repairs and renewals. Any expenditure that adds to the inventory cost of a road is an addition or betterment and should be charged to the property account. By this criterion it follows that if a worn 6 in. macadam is scarified and increased in thickness to 8 ins., the first cost of a 6 in. macadam is deducted from the first cost of an 8 in. macadam, and this difference is charged to the property account. The balance of the expense involved in scarifying, metalling, rolling, etc., should be charged to the maintenance account under the head of renewals.

The writer prefers to keep distinct the two kinds of maintenance—repairs and renewals. Under repairs are charged patching, patrolling, and other small or continuous maintenance expenses. Under renewals are charged general resurfacing and all renewals of large parts or units. Thus, in the case of a bridge the cost of painting is a repair expense; but the replacement of an old bridge by a new one is a renewal.

Since it is rare that a highway official will find a properly kept set of construction and expense ledgers left by his predecessor, the question arises whether it is worth while to inventory or appraise the existing roads. Most emphatically it is worth while. One of the best ways of rating the annual maintenance cost of any structure or machine is as a percentage of its first cost. Obviously this cannot be done where the first cost is not even vaguely known. Estimates of future maintenance expenses are often best determined by taking percentages of the first cost of each item. These reasons alone warrant making an appraisal of any plant, but, in addition the owners of a plant are entitled to know how much capital is invested in it. Who can tell, with any degree of accuracy, how much capital is now invested in the roads of any large State in America?

The writer has made a rough estimate of the investment in roads in each State, and it serves at any rate to disclose sad disparity in capital invested in roads compared with railways. Accurate figures of this sort for each State should serve to awaken the public to realization of its past niggardliness in road improvement. Now that the Interstate Commerce Commission has begun the appraisal of all the railways, it will soon be possible to contrast the investment in railways with the investment in roads, provided we begin soon to appraise our highways.

In opening a property account for a system of roads, it will be well to study the printed instructions to railway accountants issued by the Interstate Commerce Commission; also the printed instructions issued by various State public service commissions.

The writer would suggest a property account for roads as follows:—

Road Property Account.

1. Engineering, Superintendence and Inspection.
2. Administration and Legal.
3. Real Estate and Right-of-Way.
4. Clearing and Grubbing.
5. Grading.
6. Retaining and Slope Walls.
7. Bridges, Culverts and Drains.
8. Fences and Signs.
9. Trees, Sod and Foliage.
10. Paving.
11. Buildings and Fixtures.
12. Furniture and Instruments.
13. Stores and Supplies.
14. Tools and Machinery.
15. Miscellaneous.
16. Bond Discount.
17. Interest During Construction.

All existing roads should be appraised at the cost of reproduction *new*. The depreciated condition may be

* Read at American Road Congress, held at Detroit, Mich., Sept. 29th to Oct. 4th, 1913.

ascertained, but it is the cost new that should always appear in a plant account. It is now considered bad accounting to "write off" any part of plant value because of depreciation. Preferably a separate account called Depreciation Reserve is provided.

Having opened the construction ledger of a system of highways, using the appraised cost of reproduction new to start with, the cost of every new road and every betterment should be entered in that account, item by item. Many of the 17 items above given should be classified into sub-items. Of course, each new road improvement should have its own separate itemized account, and it would be well to adopt the method used by railways in designating each improvement by a numbered A. F. E. An A. F. E. is an "Authorization for Expenditure." It is made by filling in a printed blank with an itemized estimate of quantities and cost of the proposed improvement and the reasons why the improvement should be made. It is given a serial number, and signed by various officials. Care should be taken to keep the record of actual cost in such a way that it can be entered in detail on the original A. F. E. in a column parallel to the column of estimated cost. If the totals of the two do not check within 10 per cent., reasons should be given for the difference. Instead of extending a given A. F. E. to cover more work than was originally contemplated, the writer prefers to issue a separate A. F. E. for the extension.

Corresponding to the A. F. E. for large additions and improvements is the W. O., or "Work Order," for minor betterments and maintenance. Work orders should be numbered serially, and, where possible, should contain detailed estimates of cost as well as the actual cost in equal detail. In addition, a work order should show in detail how the actual cost is prorated between Maintenance and Improvements.

The location of the work should be described on each A. F. E. and W. O., but, in addition, there should be a map record of every A. F. E. Care should be taken to enter on the map the number of the A. F. E., and on the A. F. E. should be recorded the map number. If this is not done, it often becomes difficult in subsequent years to correlate the maps and A. F. E's.

In addition to a system of accounts that find final summary in two sets of ledgers, namely, Construction Ledgers and Maintenance Ledgers, there should be a separate system of unit cost-keeping records. Ledger accounts must be precise. Cost-keeping records, however, need only be approximate; for the main object of cost-keeping is to ascertain unit costs with sufficient accuracy to determine whether work is being economically done. Of course, unit costs also serve for estimating the cost of projected work, but this is a matter of small importance contrasted with the use of unit costs as a criterion of efficiency. Accounting is a function of book-keepers and accountants, but cost-keeping is a function of engineers. By this I do not mean to imply that engineers should not understand accounting, nor do I mean that there should be entire divorce of accounting from unit cost-keeping. To attempt to record in ledgers the data needed in calculating all unit costs results in greatly complicating the accounting system. Moreover, a good accounting system lacks the flexibility so essential in a good system for recording unit costs. As a rule, the engineer in charge of work finds it desirable to change the method of recording unit costs to fit the local conditions, the character and magnitude of the work, and the sort of men available for keeping the records. An accounting system, on the other hand, should remain the same for all jobs and from year to year.

Of course, unit cost records should show labor and material costs separately. It is desirable that the same separation should also be followed in the accounting system. When this is done it is possible to check roughly the total payroll charged in the ledgers against the total labor cost recorded by the engineers on their cost blanks. Similarly with the total cost of materials. Errors are thus frequently disclosed, and occasionally the "padding" of payrolls and other dishonest acts are brought to light.

Too much stress cannot be laid on the economic necessity of detailed unit cost-keeping. Even for the smallest of jobs, unit costs should be ascertained, if for no other reason than to show that unit costs on small jobs are often several fold as great as on large jobs of the same character. Much money is annually wasted in puttering. Once the total waste is expressed in dollars it usually is seen that most of the puttering can be done away with entirely. This is particularly true of road maintenance. The writer is of those who believe that too much road maintenance consists of patching in small units. There is not a little economic falsehood in applying too literally the "stitch in time" policy. Unit costs, and nothing but unit costs, will show to what extent it is economic to use a parole system of repairing.

To unit costs we must also look for the answer to the question whether day labor or contract labor is more economic. Practically all the recorded unit costs relating to road construction indicate that contract work is cheaper than day labor work The *a priori* reasons for this are numerous; but since there are not a few men who believe they can "save the contractor's profit" simple justice demands that they prove it by recording and publishing the unit costs that occur when they attempt to do so.

In conclusion, the writer would repeat the suggestion that the accounting methods of railways and other public utilities be thoroughly studied by those who are in charge of highway construction and maintenance.

It is not sufficient merely to know the principles of double entry book-keeping as it is commonly applied in business enterprises. Public utility accounting is a special science that involves many departures from the ancient art of book-keeping from which it has evolved.

THE SERVICE RAILWAY OF THE ST. LAWRENCE PULP AND LUMBER CORPORATION, PABOS MILLS, GASPE, P.Q.

By E. S. M. Lovelace, B.A.Sc.,
Civil and Consulting Engineer, Montreal.

THE St. Lawrence Pulp and Lumber Corporation, after purchasing the valuable timber limits and other holdings of the old Pabos Lumber Company, have set about to develop its property along the most modern lines. A sulphite plant with a capacity of over 100 tons of pulp per day is being erected, and saw and rossing mills are also under construction. A townsite is being laid out in the vicinity and, in addition, a standard gauge railway to the interior is now well under way. The writer has been engaged throughout the summer on the location of this railway, and there are a number of points connected with it that will be of general interest.

The peninsula of Gaspé is about one hundred and fifty miles long by seventy-five miles wide, and forms a veritable hog's back between the St. Lawrence River to the north and the Baie de Chaleur to the south. As the height of land in the interior rises considerably above sea-

level, the streams on either side of the divide necessarily have heavy falls. The water is thrown off very rapidly and even in time of freshets these streams, for the most part, carry no great body of water. As a consequence of this lack of stream flow, driving operations have not proven very successful, and have hitherto been confined almost exclusively to a few of the larger streams, leaving whole areas of spruce, balsam, birch and cedar quite untouched by the axe. Any method, therefore, by which this vast quantity of timber might be placed on the market, either in the form of pulp or otherwise, should, and in due course must, receive the serious attention and consideration of those engaged in the lumbering industry in the province.

In the development of the plant under consideration, it is proposed to largely follow methods which have proven successful in the State of Virginia, where the president of the corporation, Mr. Robert Whitmer, of Philadelphia, has other large interests. The main line of railway running back from the mill site at Pabos Mills to the timber limits in the interior, will have maximum grades of about 3 per cent., with curves up to 20 degrees being employed. The main-line locomotives being rod engines of special design, are guaranteed to take curves of even 50 degrees, if necessary. So far as the line was located it has been found possible to have, with the loaded trains, either down or level grades, so that only the trains going back light to the woods have any up grades to encounter. This will naturally reduce the cost of operation.

The rails used are sixty lbs. with standard angle-bar connections. The main-line has been substantially built, but lacking, of course, the same degree of excellence required in a line intended for passenger traffic. From the main-line, branches will be constructed, as required, down the various gullies to the lumber camps. On these branch lines engines of a different type from those in use on the main-line will be employed. They are known as the Shea engines, and are specially constructed for climbing heavy grades, the drivers and tender wheels on one side being geared to a longitudinal shafting. There is thus no dead centre, and such engines will lift a load up grades that for ordinary rod engines would be quite out of the question. Grades of even 6 and 8 per cent. can be easily operated upon with such engines. Their speed, however, is slow, about ten miles per hour under favorable circumstances being the limit. It is for this reason that on the main-line there will be an advantage in using the ordinary type of rod engine.

The construction work on the railway this season was done entirely by day labor, but next spring some further sections may be let out to contractors. The main-line has now been constructed a distance of 4 miles into the interior, where it connects with a branch to the first lumber camp. Cutting will therefore proceed through the entire winter at this camp, the wood being brought to the mill by train.

There is a deep water wharf at Pabos Mills, with connecting siding from the mill, so that in summer, when required, shipments can be made by water. Sidings from the mill also connect with the line of the Atlantic, Quebec and Western Railway, and shipments over this railway make connections at Metapedia with the Intercolonial.

The corporation was organized early in 1913. Mr. H. W. Racey, who for some years was connected with the lumbering interests of Price Bros., Limited, Quebec, and of Mackenzie-Mann & Company interests in the far West, is general manager. The corporation is composed of a group of capitalists, most of whom are, or have been, heavily interested in lumbering operations throughout the United States.

COAST TO COAST.

Esquimalt, B.C.—A new system of 128 lamps has been installed and put into operation by the British Columbia Electric Railway Company at Esquimalt, and has marked a new departure in the history and progress of the municipality.

Saskatoon, Sask.—The initial thirteen and a half miles of municipal street railway was set in operation on January 1st, 1913, and almost from the first showed a margin over operating expenses. This margin has increased from a negligible quantity to a gratifying profit.

Toronto, Ont.—An endeavour is being made to bring about reciprocity in boiler inspection by the public works departments of British Columbia, Ontario, Saskatchewan and Alberta. The standards of the provinces are almost identical, and no obstacle should stand in the way of the desired reciprocity.

Port Arthur, Ont.—The C.P.R. has under way an extensive piece of work at Current River. The river has been turned off to one side, and steam drills are being employed at excavation work prior to the construction of the subway under the bridge. Before the subway can be completed, a large quantity of rock must be removed, which is now part of the bed of the river.

Le Pas, Man.—A new wireless station has been built by the Marconi Wireless Company at Le Pas, in connection with the construction of the Hudson Bay Railway, and as soon as all the apparatus in connection with the station is complete, the company will be prepared to receive commercial business along this and connecting wireless chains. This new station will eventually be a link in a chain that will be perfected when the Hudson Bay and Strait have been opened to navigation.

Regina, Sask.—There now seems every likelihood that the City of Regina will enter into an agreement with Mr. A. S. Porter, which will result in a material reduction in the cost of electrical energy. Mr. Porter owns large deposits of lignite coal in the southern part of the province, and he has advanced several propositions to the city, one of which is that a company in which he will be interested will generate power from the lignite coal, and sell the power at a low rate to the city, the city to retail and distribute it. Mr. Porter is now in the city for the purpose of going further into detail with regard to the proposition. Readers will remember mention of this proposal some time ago in *The Canadian Engineer*

St. John, N.B.—Some interesting data has been furnished concerning dredging operations, which have been in progress from April 1st up to the present, at the St. John harbor, exclusive of Courtenay Bay. The work accomplished has been the dredging at the mouth of the channel required to straighten its entrance, the removal of foul ground, the dredging of the Beacon Bar and the making of the berths at the West Side, where the new wharves are being constructed, the clearing up of the present berths, the deepening of Wellington and Nelson slips, the dredging of the Navy Island Bar in the course of the ferry boat, and the deepening of the West berth at the I.C.R. wharf. In all, these operations represent the dredging of one and a quarter million cubic yards of material.

Brantford, Ont.—Another favorable report on railway construction has been given in connection with the L. E. and N. Railway. The track-laying is in progress, and the rails have been laid southward from Galt to a point 1,200 yards below the power-house at Blue Lake. From the Grand Trunk Crossing at Blue Lake to Paris, and from the crossing of the same railway to the city of Brantford the road bed is ready to have the rails laid. Just as soon as the subway under the Grand Trunk tracks at Blue Lake and Paris are completed, the rails will be laid into Brantford and the ballasting will be done. Contractors are pushing the subway work as fast as possible and Mr. Kellett still has hopes that the Northern branch will be running before the close of 1913.

Fort William, Ont.—The work of drilling and blasting the solid rock under Lake Superior for the new tunnel which will supply Port Arthur with a new water service, has been started and considerable progress made. About 10 feet is being accomplished every 24 hours. Owing to the fact that air pressure in the tunnel will be kept at twenty pounds to the square inch, the work cannot be very rapid; since the very strongest men can not stand being in twenty pound air pressure, or even less for more than a very few hours. The work in the water intake tunnel will be done in shifts of a specified number of hours each. Mr. J. Gass, superintendent of the work, states that in all probability the work will not be finished until next April.

Rogers Pass, B.C.—The C.P.R. will take four years to complete the tunnel now under construction at Rogers Pass in the Selkirk range. This huge tunnel which will require an expenditure of 15,000,000 dollars for its completion is being built for the purpose of lowering the grade through the mountains. Five and three-fifths miles of its total length of 20 miles must be driven through solid rock, and on either side there will be an approach of 7 miles. To carry out the construction, shafts a mile deep will have to be driven through the mountains. The company has undertaken one of the greatest pieces of railway construction work in this age, and one which will dwarf into insignificance all other tunnels in the world.

Regina, Sask.—The Grand Trunk Pacific Railway has opened recently a 105-mile piece of road on its new Calgary-Biggar branch. This stretch of 105 miles lies between Biggar and Loverna, which lies on the boundary line between Saskatchewan and Alberta. Permission has been granted by the Board of Railway Commissioners also for the operation of 50 miles of the Regina-Moose Jaw and Northwesterly branch of the G.T.P., which have been completed to a short distance beyond Mawer, Sask. Ballasting on the Tofield-Calgary branch of the G.T.P. has been finished to Calgary, and first-class passenger service will be established as soon as the terminals at Calgary are completed. This line is a solid construction, and as a consequence will give a splendid service between Calgary, Tofield and Edmonton.

Vancouver, B.C.—In the opinion of Mr. H. H. Stevens, M.P., the people of the Vancouver district should proceed in a business-like way with the construction of the Second Narrows bridge, making no further requests for aid from either the Provincial or Dominion Government. Mr. Stevens emphasized the need of a strong expression of public opinion on the subject to enable the city and municipal authorities to advance plans for procuring the money necessary for the bridge construction. The subsidies subscribed by the governments, and the amounts authorized by the councils of the various districts have brought the total subscription up to $750,000 of the necessary $2,500,000. The councils interested should exercise now their borrowing powers and proceed at once with the erection as a good business proposition.

Halifax, N.S.—That work has been commenced by terminal builders at Halifax may be verified by a picturesque quotation from a local daily paper. "A blackened swath of desolation, gashed through over a mile of what once was the finest of all the natural beauty of Halifax, now marks the preliminary work on the fantastic south end terminal scheme, and fire and axe are daily advancing the work of devastation. Some of the finest public grounds and seven of the beautiful private estates in the city have already been irreparably ruined. From the harbor front a pathway over one hundred yards wide has been gouged along the line of the proposed ditch railway which is to increase the length of the passenger and freight haul to this city from every point to which Halifax has railway connection."

St. John, N.B.—Though the engineers of the J. S. Metcalf Company, contractors to the Federal Government for the building of the new grain conveyers, have made their surveys, the building of the conveyers has not been started. The galleries for the conveyers are to be constructed on hard pine timbers, 54 feet long and 12 inches square, and these timbers have to be secured in the United States. This may be the cause of delay in the work; but if the conveyers are to be available for the shipment of grain at the commencement of the season, very rapid operations will be necessary to complete their construction before the opening of the winter port season. The new conveyers will be more than 2,000 feet long, and will have about 8,000 feet of rubber belting 36 inches wide, costing about $1.00 per foot. These belts will be driven by four 75 horse-power electric motors installed in towers on the galleries. The work of building the conveyers progresses very rapidly when once begun, as while the foundations are being made the gallery tressel is prepared. At Sand Point now it appears that to supply the new berths with conveyers necessitates construction work as extensive as that represented by the conveyers already built. At the present time conveyers are built on berths Nos. 1, 2, 3 and 4. It is probable that the new conveyers will continue from the end of No. 1 berth, and cross the head of the slip along Union Street and then pass down the face of the berths Nos. 5, 6 and 7.

Port Nelson, B.C.—Mr. H. E. Penrose, writing from Port Nelson to the Winnipeg Free Press, says:—"Amongst Canada's great engineering achievements—and these are not a few—the completion of the harbor at Port Nelson will probably rank with the foremost. Whilst the site and climatic conditions of the harbor are by no means perfect, the difficulties are being gradually surmounted; step by step accurate survey and charting have been accomplished, and with the mass of information obtained, plans have been drawn up and the work of construction begun." To carry out the undertaking so that it will be of permanent good, and free from danger of destruction, two breakwaters will have to be built at a point 15 miles up the river to protect the wharfs and harbor works from ice coming down stream as well as to break the force of the current, which has been quoted as one of the arguments against the ultimate success of the project. Below these breakwaters, it is proposed to build an elevator capable of dealing with large quantites of grain at a rapid rate, and to dredge a channel so that ships of moderate tonnage may come alongside. A further suggestion has been the use of floating elevators either in conjunction with or separate from the larger one on shore. Close to the construction camp is the site of the wireless station which will communicate with Le Pas. This high power station acting in conjunction with the proposed chain of stations along the bay to the entrance of the strait, and a possible government scout operating along the track, could communicate full information to ship captains regarding the condition of the route many hours before entering the straits.

PERSONAL.

J. L. LANG, B.A.Sc., has accepted a position in Galt as assistant to the City Engineer, C. D. Campbell.

C. R. HOLMES, B.A.Sc., has joined the Chicago staff of the Hoskin Manufacturing Company, of Detroit, as salesman for electric furnaces, pyrometers, etc.

T. G. HASTIE, Division Engineer in British Columbia for the Great Northern Railway, is conducting the inspection of development work on the Victoria and Sidney Railway, B.C.

WYNN MEREDITH, Consulting Engineer for Victoria on the Sooke Lake water supply project, is recovering from a severe illness in a Los Angeles hospital, and is expected in British Columbia soon again.

M. T. CANTELL, Lic. R.I.B.A., A.S.I., Professor of Architecture and Civil Engineering, Municipal Technical College, Brighton, Eng., and author of "Reinforced Concrete Construction," has become associated with the Success College of Science and Trade, Winnipeg, as Principal.

RUSSELL G. SWAN, B.A.Sc., an honor graduate in Civil Engineering, University of Toronto, has been promoted to the position of Chief Engineer of the British Columbia Hydrographic Survey of the Department of the Interior. As Mr. Swan has had considerable experience in hydrographic survey work, especially in connection with water powers in various parts of the West, he is well qualified for his work. Mr. Swan's headquarters will be in the Dominion Government offices at Vancouver.

A. M. BEALE, B.Sc., Engineer of the Water Power Branch of the Department of the Interior, is now in the West making an investigation of the question of the development of small water powers of less capacity than 200 horse-power which would be of advantage to small communities. It is understood that there are at present a number of applications before the Department for the right to develop such small schemes in various parts of the Provinces of Manitoba, Saskatchewan and Alberta. While these are of small capacity, they are in many cases of great importance to the particular district affected. Mr. Beale's investigations will be watched with considerable interest, as the question of the utilization of power for farm and small mill purposes has been already demonstrated to be a success in various States of the Union, and also in our own Province of Ontario, where the Ontario Hydro-Electric Commission has been able to demonstrate that the milkmaid and the old hand-pump are no longer an absolute necessity.

N.T.R. CONSTRUCTION.

At the October meeting of the Canadian Railway Club, held at the Windsor Hotel, Montreal, Mr. R. F. Uniacke, Bridge Engineer of the National Transcontinental Railway, gave a most interesting illustrated lecture covering some of the difficulties encountered in the construction of the road, showing in some detail the undertakings, their problems and the solutions.

Some of the greatest difficulties he mentioned were due to clay subsoil not capable of bearing the weight of a heavy fill. In one instance the approach to a bridge was shown where the concrete pier at once end and the first span had been entirely carried away. Another was of a deep fill which began to move down along the river, which it approached, as soon as completed, and refused to be stayed. These and similar difficulties were constantly being met.

The speaker stated that the rails were now joined from Moncton to Winnipeg, with the exception of the crossing of the St. Lawrence at Quebec, which awaited the completion of the bridge. Meanwhile a ferry was being built which would be in operation next May. There had been difficulties to overcome in ferrying trains across the St. Lawrence, both winter and summer, in the flow of ice, the rise and fall of the tide, and, as a consequence of this latter, the freezing of the water on the sides of the docks, which sometimes reached a thickness of eight and nine feet. The ferry boat finally decided upon was to be constructed with a tidal deck, with a rise and fall of eighteen feet, and with an "apron" at each end, which joined the rails of the boat with those of the docks.

ONTARIO ASSOCIATION OF ARCHITECTS.

At the twenty-fourth annual convention of the Ontario Association of Architects the following officers and Council were elected for the year: President, C. H. Acton Bond, Toronto; first vice-president, Herbert E. Moore, Toronto; second vice-president, L. Fennings Taylor, Ottawa; treasurer, J. P. Hynes, Toronto; registrar, Franklin E. Belfry, Toronto; and Colborne P. Meredith, Ottawa; J. W. Powers, Kingston; W. R. Gregg, Toronto; W. W. Stewart, Hamilton; Charles E. Langley, Toronto, Council.

AMERICAN SOCIETY FOR MUNICIPAL IMPROVEMENTS.

At the annual meeting, held in Wilmington, Del., recently, the following officers were elected for the ensuing year: President, Edward H. Christ, of Grand Rapids; first vice-president, W. A. Howell, of Newark, N.J.; second vice-president, A. F. Macallum, of Hamilton, Ont.; third vice-president, N. S. Sprague, of Pittsburg; secretary, C. C. Brown, of Indianapolis; treasurer, W. B. Howe.

Boston was selected for the 1914 convention.

COMING MEETINGS.

NATIONAL SOCIETY FOR PROMOTION OF INDUSTRIAL EDUCATION.—Annual convention to be held at Grand Rapids, Mich., October 19th to 25th. Secretary, C. A. Prosser, 105 E. 22nd Street, New York City.

AMERICAN MINING CONGRESS.—Annual convention will be held at Philadelphia, Pa., October 20th to 25th. Secretary, J. Callbreath, Majestic Building, Denver, Colo.

AMERICAN RAILWAY BRIDGE AND BUILDING ASSOCIATION.—Annual convention will be held at Montreal, Que., October 21st to 23rd. Secretary, C. A. Lichty, 319 N. Waller Avenue, Chicago, Ill.

UNITED STATES GOOD ROADS ASSOCIATION.—Convention will be held at St. Louis, Mo., November 10th to 15th. Secretary, J. A. Rountree, L021 Brown-Marx Building, Birmingham, Ala.

NATIONAL MUNICIPAL LEAGUE.—Annual meeting will be held in Toronto, November 12-15. Secretary, C. R. Woodruff, 705 North American Building, Philadelphia, Pa.

AMERICAN ROAD BUILDERS' ASSOCIATION.—Tenth Annual Convention to be held in First Regiment Armory Building, Philadelphia, Pa., December 9th to 12th. Secretary, E. L. Powers, 150 Nassau Street, New York, N.Y.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS.—The annual meeting will be held in New York, December 2nd to 5th, 1913.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for small fee.

20505—October 6—Approving location C.P.R. station yard in block of land lying north-westerly of Haskell Street and south-easterly of Fox Street, town of Port Hope, Ont., at mileage 125.70 from Glen Tay.

20506—October 6—Approving locations of C.N.O.R. station grounds, Dist. Nipissing, Ont., as follows:—Master, mileage 111.05 from Ottawa, township of Master and Kathmore, mileage 115.5 from Ottawa, township of Master.

20507—October 6—Directing that C.P.R. provide and construct an additional track to present siding accommodation for use of Dodge Manufacturing Co., Limited, at their works, at West Toronto: work to be completed within 60 days from date of Order.

20508—October 7—Authorizing C.P.R. to construct, at grade, tracks of spur to Broadacres Ballast Pit across highway between Secs. 7 and 8, Con. 36, Rge. 21, W. 3 M., on C.P.R. Kerrobert North-easterly Branch.

20509—October 7—Authorizing C.P.R. to operate two (2) bridges—namely, Bridge No. 27.4 St. Stephen Subdivision, Atlantic Division, and Bridge No. 13.9, St. Stephen Subdivision, Atlantic Division.

20510—October 7—Authorizing C.P.R. to construct bridge No. 15.6 over Eagle River, Shuswap Subdivision, B.C. (double track).

20511—October 7—Authorizing C.P.R. to operate Bridge No. 30.5, Gibson Subdivison, Atlantic Division, of its line of railway.

20512—October 7—Extending until December 31st, 1913, time within which G.T.R. install interlocking plant at Paris Jct., Ont., approved by Order 18734, dated February 18, 1913.

20513—October 7—Authorizing, temporarily, G.T.P. Branch Lines Co., to carry traffic over portion of Cutknife Branch between Battleford, mileage 0, and Rossman Station, mileage 33.6, Sask.: operation of trains over said line be limited to speed not exceeding 15 miles an hour.

20514—October 6—Directing that, within 60 days from date of this Order, M.C.R.R. Co. install an illuminated electric sign and an improved type of automatic electric bell at crossing of highway at Townsend Station, between Cons. 8 and 9, Co. Haldimand, Ont.: cost of installing said sign and bell to be paid out of "The Railway Grade Crossing Fund," and remainder by Railroad Co.

20515—October 7—Approving revised location C.N.R. Delisle-Alsask Branch in S.E. ¼ Sec. 9-26-17, W. 3 M., Sask., mileage 62½.

20516—October 6—Amending Order No. 19731, dated July 3rd, 1913, to provide that Winnipeg, Selkirk and Lake Winnipeg Ry. Co., operate its cars and trains across C.P.R. from 6 a.m. to 11 p.m., instead of between hours of 9.45 a.m. and 2 p.m. and 12.30 a.m. and 6.30 a.m.

20517—October 7—Authorizing C.N.O.R. to construct bridge to carry its railway over White's Creek, mileage 64.9 from Ontario, Ont.

20518—October 11—Approving, subject to terms of agreement, proposed station site and station of G.T.P. Ry. at Fort Fraser, mileage 372.8, Prince Rupert East, in Sec. 26-15-5, Coast District, B.C.

20519—October 9—Authorizing G.T.P. Branch Lines Co., to construct Tofield-Calgary Branch across highway at mileage 196.6, between Sec. 33-23-29, and Sec. 4-24-29, W. 4 M., Dist. South Alberta, Alta.

20520—October 14—Authorizing G.T.P. Ry. to construct across two (2) highways in B.C.—namely, 1. Mileage 370, Prince Rupert East, Lot 2004A, Rge. 5, Coast District, and 2. Mileage 373, Prince Rupert East.

20521—October 8—Amending Order No. 20402 dated September 24th, 1913, by striking out words "Grand Trunk Pacific Railway" where they occur in said Order, and substituting therefore words "Grand Trunk Pacific Branch Lines Company's Regina-Boundary Branch."

20522—October 7—Granting leave to G.T.P. Branch Lines Co., to operate its trains over crossing of C.P.R. Co.'s Calgary to Edmonton Branch, in city of Calgary, pending installation of interlocking plant required to be provided at said crossing, subject to certain conditions.

20523—October 9—Authorizing G.T.P. Ry. to construct across highway between Secs. 22 and 23-40-23, W. 3 M., and construct road diversion in N.E. ¼ Sec. 22-40-23, W. 3 M., mileage 15.8, Rural Mun. Round Valley, No. 410, Sask.

20524—October 8—Authorizing C.P.R. to use and operate bridges Nos. 36.5, 43.8, 43.4, 43.3, 34.4, 24.8, 30.7 and 32.2, on its Farnham Subdivision, Eastern Division.

20525—October 6—Authorizing London Street Ry. Co., to operate its trains over crossing of Adelaide Street, London, Ont., without their being brought to a stop.

20526—October 7—Authorizing C.P.R. to construct an additional track (double track) across St. Francois-Xavier Street, mileage 6.89, and Jacques-Cartier Street, mileage 6.5, at grade, town of Farnham, P.Q.

20527—October 11—Authorizing C.P.R. to construct crossing over its railway at Station 3100-10, Ensign, Alta.

20528—October 8—Authorizing C.P.R. to open for traffic that portion of double track between mileage 70 and Herbert, mileage 81.9, Swift Current Subdivision, Sask.

20529—October 10—Authorizing C.L.O. and W. Ry. to divert, upon terms agreed to between Tp. Bedford and Ry. Co., road in Lot 26, Con. 1, Tp. Bedford, along Con. Line, between Cons. 1 and 2, to a crossing at mileage 23.71, authorized under Order No. 16758, dated June 15th, 1912. Work authorized hereunder, with exception of fencing, be done by Tp. and completed by July 31st, 1914.

20530—October 14—Approving location and revised location C.P.R., Weyburn-Stirling Branch, from a point in Sec. 32-6-15, W. 4 M., mileage 24.74, thence in easterly direction to a point in Sec. 13-6-9, W. 4 M., mileage 64.34.

20531—October 14—Authorizing C.P.R. to construct bridge No. 19.8, Farnham Subdivision, Eastern Division, over Chambly Canal, St. Johns, Quebec.

20532—October 14—Extending, until May 1st, 1914, time within which C.P.R. construct and complete spur for Coquitlam Terminal Co., Limited, Vancouver, B.C., across Dominion, 5th, 6th and 7th Avenues.

20533—October 14—Authorizing C.P.R. to construct, by means of a grade crossing, tracks of its gravel pit spur, at Waldeck, across highways between N.W. ¼ Sec. 18-16-12, W. 3 M., and N.E. ¼ Sec. 13-16-13, W. 3 M.; and between N.W. ¼ Sec. 19 and S.W. ¼ Sec. 30-16-12, W. 3 M., Sask. Div., Swift Current Subdivision.

20534—October 7—Anthorizing C.P.R. to construct spur for Calgary Stock Yards Co., Limited, situate in N.E. ¼ Sec. 11-24-1, W. 5 M., Alberta, subject to terms and conditions of agreement, with exception of condition referring to removal of said spur from off said street (Burns Avenue, Calgary), when ordered by city to do so. Rescinding Order No. 19472, dated June 4th, 1913.

20535—October 9—Authorizing C.P.R. to construct siding into premises of D. L. Streight, Lot 7, Con. A, Tp. Etobicoke, Co. York, Ont., at Islington, Ont.

20536—October 8—Authorizing C.P.R. to use and operate three (3) bridges on Farnham Subdivision, Eastern Division—namely, No. 35.8, 26.6 and 28.8.

20537—October 9—Authorizing C.L.O. and W. Ry. to construct bridge over Smithfield Creek, near mileage 93.7, Ont. .(Murray-Brighton Road Diversion.)

20538—October 14—Approving location C.P.R. station in Part Lot 28, Con. 2, Tp. Clarke Co. Durham (West Riding), Ont., at mileage 143.03 from Glen Tay.

20539—October 10—Authorizing C.P.R. to construct spur for city of Moose Jaw, from a point on existing spur on North Bridge Street, thence across North Bridge Street and across Subdivision, Lots 5, 6, 7 and 8, Block 142, City of Moose Jaw, to and into premises of city of Moose Jaw, in Block 142.

20540—October 9—Authorizing C.P.R. to construct spur for J. K. McInnis, Regina, Sask.

20541—October 10—Authorizing C.P.R. to construct bridge No. 117.42, Shuswap Subdivision, B.C. Division, British Columbia.

20542—October 10—Authorizing C.P.R. to construct spur for (1) Imperial Oil Co., Limited, situate in Lot 1, Block A, town of Bassano; and (2) Calgary Brewing and Malting Co., Limited, situate in Lot 2, Block A, town of Bassano, Alta.

20543—October 13—Authorizing C.P.R. to construct, by means of a grade crossing, its passing track and leg of wye across road allowance between Secs. 35 and 36-14-13, W.P.M., on Minnedosa Subdivision, Manitoba Division.

20544—October 6—Authorizing C.P.R. to construct, at grade, tracks of extension to town siding at Ekoba, across public road between N.E. ¼ Lot 19, and S.E. ¼ Lot 18, Tp. McDonald, District Algoma, Ont., in village of Ekoba.

20545—October 9—Approving C.P.R. plan, as amended by Chief Engineer of the Board, showing proposed interlocking plant to be installed on temporary trestle at Pitt River, Bridge 109.7, Cascade Subdivision, B.C. Division.

20546—October 13—Authorizing Esquimalt and Nanaimo Ry. Co. to open for freight traffic portion of its railway from McBride Jct., to Courtenay, Vancouver Island, a distance of 8.5 miles: Provided speed of trains be limited to rate not exceeding 12 miles an hour.

20547—October 8—Authorizing C.N.R. to open for carriage of freight traffic its line of Ry., from St. Albert westerly to mileage 22, a distance of 22 miles, Alta.

20548—October 14—Approving and authorizing clearances as shown on plan showing clearances of Moose Jaw Cold Storage Co., Limited's building on C.P.R., subject to conditions that Ry. Co. order its men to keep off sides of cars; and that speed of cars on siding be limited to speed not exceeding four (4) miles an hour.

20549—October 6—Approving location C.P.R. station in Lot 25, Con. 10, Tp. Mara, Co. Ont., at Uptergrove, at mileage 55.64, Port McNicoll Subdivision, Ont. Division.

20550—October 14—Authorizing ratepayers of Tp. Osgoode, Co. Carleton, Ont., at their own expense, to construct highway crossing over C.P.R. Co.'s gravel pit spur in Lots 27 and 28, Con. 1, Tp. Osgoode.

20551—October 9—Authorizing T.H. and B. Ry. to open for traffic that portion of new second track from Welland River to Fenwick Station, mileage 1.35 to mileage 6.47 from Welland.

20552—September 18—Dismissing complaint of certain residents of Tps. March and Torbolton, Co. Carleton, Ont., against location station by C.N.O.R., at mileage 22 from Ottawa, Tp. March, approved under Order No. 17342, dated August 27th, 1912.

20553—October 11—Extending, until December 1st, 1913, time within which B.C. Electric Ry. Co., complete work at crossing of tracks of Esquimalt and Nanaimo Ry., near Russell, B.C., required under Order No. 18733, dated February 18th, 1913.

20554—October 10—Relieving Red Mountain Ry. Co., from fencing certain portions of its right of way from International Boundary, south of Patterson, to Rossland, B.C.

20555—October 10—Relieving V.V. and E. Ry. and Nav. Co., from fencing certain portions of its right of way from Midway, B.C., to International Boundary, west of Bridesville, B.C.

20556—October 10—Authorizing Edmonton, Dunvegan and B.C. Ry. Co., to construct across fifteen (15) highways in Prov. Alta.

20557—October 9—Directing that G.T.R., at its own expense, provide and construct farm crossing over its railway where same crosses farm of Charles Ellis of Toronto, in Lot 45, Front Range, Tp. Rama.

20558—October 13—Authorizing G.T.R. to reconstruct bridge No. 278, at mileage 73.75, Thirteenth Dist., over Nottawasaga River, near Beeton, Ontario.

20559—October 14—Authorizing G.T.R. to construct siding into premises of Canada Brick and Fireproofing Co., Limited, on part of Lot 27, Con. 11, Tp. Esquesing, Co. Halton, Ont.

20560—October 13—Authorizing G.T.R. to reconstruct Bridge No. 101, at mileage 309.14 on its 32nd Dist., Ottawa Div., carrying its railway over Joe Creek.

20561—October 10—Authorizing G.T.R. to operate its trains over swing bridge across Welland Canal, and railway crossing at Port Colborne, without their first being brought to a stop.

20562—October 14—Authorizing C.P.R., for purpose of constructing a reservoir for sufficient maintenance and operation of its railway, to take all that portion of S.E. ¼ of Sec. 8, Tp. 12, Rge. 19, W. 2 M.

20563—October 13—Approving location C.L.O. and W. Ry. (C.P.R.) station in port Lot 26, Con. 2, northwesterly of Beech Street and easterly of Brock Street, town of Whitby, Co. Ont., Ont., at mileage 164.17 from Glen Tay.

20564—October 8—Rescinding Order No. 20245, dated August 30th, 1913.

20565—October 9—Authorizing C.N.O.R. to construct across and divert Second Avenue, town of North Bay, Ont.

20566—October 6—Relieving M.C.R.R. from maintaining cattle-guards at crossing of Plymouth Road, town of Welland, Ont.

20567—October 15—Extending, until December 1st, 1913, time within which C.P.R. install bell at crossing of highway at mileage 0.91 from St. Martin's Junction, Que., required under Order No. 19905, dated July 25th, 1913.

20568—October 8—Approving location C.P.R. station in north half of Lot 21, Con. 8, Tp. Richmond, Co. Lennox and Addington, Ont., at mileage 53.00 from Glen Tay, at Overton: Provided whenever it develops that traffic on highway is blocked for more than 5 minutes at any one time by reason of location hereby approved, Board shall be at liberty to re-locate said station.

20569—October 7—Approving location C.N.O.R. station grounds, at Remi, parish Ste. Genevieve, Co. Jacques Cartier, Ont.

20570—October 8—Establishing collection and delivery limits of Dominion Express Co., in city of Kelowna, B.C.

20571—October 8—Establishing collection and delivery limits of Dominion Express Co., in town of Knowlton, Que.

20572—October 15—Authorizing C.P.R. to construct diversion in Sec. 30-22-26, W. 3 M., Sask.; and construct its Swift Current Northwesterly Branch Line across said Diversion, at mileage 90.13.

20573—October 15—Authorizing C.P.R. to construct, by means of a grade crossing, across Government Road, in Lot 2567 (Provincial Government Survey), Kootenay Dist, B.C., at mileage 42.37.

20574—September 11—Approving location C.P.R. proposed station at Empress, on Swift Current Northwesterly Branch.

20575—October 7—Authorizing C.P.R. to construct siding, from a point on southerly limit of right of way, Easterly Div., Sherbrooke Subdivision, Lot Cadastral No. 1539, Sherbrooke, Que., for Canadian Connecticut Cotton Mills Co., Limited.

20576—October 7—Authorizing C.P.R. to construct a relocation of siding into premises of J. A. Villemaire, situate in Lot 9, Rge. 3, Tp. Campbell, Co. Ottawa, Ont.

20577—September 23—Amending Order No. 16671, June 1st, 1912, by striking out words, "as provided by the Ry. Act," and substituting therefore words, "by special arbitrator to be appointed by the Board." Also amending Order No. 18906, March 14th, 1913, (1) by adding words, "acquired previous to the year 1904," after word "properties," in 17th line on page 16. (2) by adding words, "as to all the properties taken," after word "shall," in 19th line of page 16. (3) By adding words "acquired previous to the year 1904," after word "lands," in 6th line from bottom of page 16. (4) By adding words, "as to properties acquired previous to year 1904," after word "awards," in 4th line from bottom of page 16 and (5) By striking out words, "in accordance with the provisions of Sec. 192 of the Rly. Act," at end of said Order.

20578—October 14—Authorizing Kettle Valley Ry. Co. to construct bridge over Fraser River, at Hope, B.C.

Tarvia

Preserves Roads
Prevents Dust~

Section of Government Parkway, Ottawa, Canada, treated with "Tarvia B."

Dust is Expensive

When an automobile speeds down an ordinary macadam road it leaves in its wake a cloud of dust which is carried by the winds over the neighboring fields, houses and lawns.

This is just as surely a waste of good material as if the automobilist dug material out of the highway and carted it away. Dust represents waste—costly waste—and the taxpayers feel the result. A road that is properly built for modern traffic will not be dusty.

Plain macadam gives way under the wear and tear of heavy rubber-tired automobile wheels and the surface binder of the road is torn away in the form of dust, until in time the coarse stone itself is exposed and a costly renewal of the road is necessary.

Modern roads should be built to resist modern traffic. To build any other kind is wasteful. A better binder than the ordinary mineral binder is needed and is offered in Tarvia, a coal tar compound especially prepared for use on roads.

Tarvia is dense, viscid, waterproof. It fills the interstices between the stone and forms a tough, plastic matrix. This makes a waterproof and automobile-proof surface. The maintenance cost is usually so low as to more than balance the cost of Tarvia treatment.

Booklets on request.

RAILWAYS—STEAM AND ELECTRIC.

Calgary, Alta.—The city commissioners have recommended the building of approximately a half of mile of street car line to connect the two stub lines extending west on Twenty-Sixth and Thirty-Fourth Avenues. The estimated cost is about $5,000.

Calgary, Alta.—It has been stated that the route of the C.N.R., north of Athabasca, has been mapped out, and that the legislature will be called upon forthwith for its approval. The line is to built from Athabasca on the south side of the river to a point five miles north-west of the town, where it will cross the river, and be constructed so as to give service to Peace River Landing and the intermediate towns.

Edmonton, Alta.—Engineers in the employ of Mr. J. D. McArthur have been engaged for some time on the preliminary surveys for the Alberta and Great Western Waterway. When the legislature of the province has accepted Mr. McArthur's proposal to build the road on a bond guarantee of $20,000 per mile, it has been officially announced that actual construction work will be begun.

Ottawa, Ont.—The acting minister of railways, the Hon. D. S. Reid, has approved the route map of the C.N.R. between Sturgis and Hudson's Bay, and the revision of the C.P.R. Swift Current branch running north-westerly near Empress. Further information must be given before approval of the revision of the C.N.R. line from Morris southwesterly, or of the Alberta Central revision in townships 26 and 27, range 24 west of the 3rd, will be granted.

Ottawa, Ont.—At the next session of parliament, an application is to be made for an act to incorporate a railway company, called the Ungava Railway Company, having power to construct a line from the Hudson Bay Company's post at the mouth of the Great Whale River, or the most desirable point thereabout, in an easterly or southeasterly direction to Aylmer Sound, or to another suitable point on the Gulf of St. Lawrence.

St. John, N.B.—A conference has been held between Secretary Hopper, of the Street Railway, and business men interested in Courtenay Bay property, and the request of residents for an extension of the railway to Little River was discussed. The outcome may be that the company will make an extension from Kane's Corner to Crouchville this fall or next spring, and further extensions thereafter when the company shall be in a position to continue the work.

Toronto, Ont.—The Dominion Railway Commission has declared that the railways must proceed with the erection of the new Union Station and the construction of the Esplanade viaduct without further delay. The work of wrecking the buildings and of cleaning up the sites for the station and viaduct is to be started within two weeks. Mr. Leonard has stated that the Union Terminal Company will doubtless make known its final plans inside of two weeks. With regard to the viaduct, Chairman Drayton assured the railway officials that, while the order had not been officially signed as yet, this was but a formality that would not interfere with the railways.

Vancouver, B.C.—The city is considering immediate action in the purchase of the B.C.E.R. The company's franchise does not expire until 1919, but Mr. Glover has stated to Mayor Baxter that the company will consider any reasonable proposition.

Vancouver, B.C.—The first reading of an agreement, which is to be incorporated in a by-law giving the P.G.E. railway right-of-way through D.L. 237, has been given in council. It is proposed to change the right-of-way setting it back some distance from the water front, and the company is to abandon its right to water fronts.

Vancouver, B.C.—The British Columbia Electric Railway has found it impossible to cope with the wishes of residents of Lulu Island, South Vancouver, and adjoining districts, and for the present cannot consider the laying of a track across Lulu Island for the benefit of the citizens in this locality.

Vancouver, B.C.—Mr. A. Reed, of Winnipeg, has visited the city, it is believed, with the object of securing a charter from the Provincial Government for a line to connect Kamloops with Quesnel and Barkerville. This will open up a splendid stretch of rich mining country. Full details of plans are expected to be issued shortly.

Vancouver, B.C.—The city solicitor was instructed by the board of works to draw up an agreement between the city and the C.P.R. Company, admitting certain conditions by which the city will take over the street and railway trackage between Homer Street and the yards.

Winnipeg, Man.—Plans have been filed for the spur line of the Midland Railway Company between Ross and Elgin Avenues, and are to be considered by the works and property committee.

GARBAGE, SEWAGE AND WATER.

Burlington, Ont.—The citizens of Burlington are demanding a sewer system which will cost in the neighbourhood of $150,000. Though agitation has been started, the construction will probably not be undertaken for a year or more.

Fort William, Ont.—Progress in improvements being undertaken in the coal dock district is reported as favorable. It is a difficult problem to get a system here that will drain the land after a heavy rainfall. Sewer has been laid on McLaughlin Street, and the street has been raised and levelled. The old ditches at the sides of the roads have been filled in and new ones dug inclining slightly towards the lake. Until the streets in the vicinity are paved, this is all that is practical to do.

Fort William, Ont.—The report of the works committee recommended the laying of sewers in several of the city streets, and the letting of contracts from tenders submitted by various local contractors.

Kerrisdale, Point Grey, B.C.—An agreement is pending awaiting ratification by the council by which the R. McLean Company will build a sewer costing $100,000 in Eburne. The company are constructing at present a sewer costing $87,000 in D.L. 540, and also have the contract for a $13,000 sewer which will be an extension to the Wilson Creek sewer in D.L. 472.

Ottawa, Ont.—The waterworks committee have decided that 180 new fire hydrants are to be installed on different streets throughout the city, within the next year at a cost of $20,000. The resolution will have to be placed before the city council asking that authority be sought from the Ontario Government to raise the money required by debentures. In the meantime, City Engineer Currie has been instructed to expend $5,000 in new hydrants.

Ottawa, Ont.—The City of Ottawa has decided to expend upon securing a pure water supply from Thirty One mile lake in the Gatineau region, Quebec, the approximate sum of $8,000,000, towards which the Dominion Government has promised a subsidy of $100,000 per year.

Regina, Sask.—The Regina works committee has decided to extend the sewerage system so as to provide drainage for the low lying land in the north-east section of the city, and also to serve the abattoir. Several additional extensions will be made in other sections of the city.

Swift Current, Sask.—Tenders will be received up till October 28th, 1913, for two contracts for the laying of sewers. Plans and specifications may be obtained from George D. Mackie, Esq., Town Engineer, Swift Current, Sask.

▲—**Toronto, Ont.**—Tenders will be received up till November 4th, 1913, for the construction of several sewers. Plans and specifications may be obtained from H. C. Hocken (Mayor), Chairman, Board of Control, Toronto, Ont.

Vancouver, P.C.—Tenders will be received up till October 29th, 1913, for the construction of the Point Grey partnership pipe from Stanley Park to Bodwell Road in alternate routes. Plans and specifications may be obtained from the City Engineer, City Hall, Vancouver, B.C. Signed, Wm. McQueen, City Clerk.

Vancouver, B.C.—The city waterworks committee has under discussion the question of acquiring the Seymour Creek timber lands for the purpose of conserving the area as a watershed and of forming a reservoir. The city cruiser has reported $319,000 as a fair valuation of the timber land and limits. However, timber limits connected with other estates would have to be purchased, and would raise the expenditure necessary. A by-law will doubtless be submitted to the people in January; for the land must be reserved by the city to obviate the risk of being polluted by campers.

Verdun, Man.—The town council has succeeded in securing $200,000 for civic improvements. The sewers to cross Church and Wellington streets will be commenced at once, so that they will be completed this fall, and pavements may be constructed on these streets early next spring. Other sewers will also be commenced this fall and if possible completed.

Victoria, B.C.—A conference of the city authorities was held in connection with the north-west trunk sewer, and the following resolution was finally adopted:—"That this meeting of the representatives of the three municipalities hereby agree to adopt as a basis of settlement the figures which have been submitted by the engineers of the municipalities in so far as they relate to the north-west sewer, and undertake to bring the subject before the respective councils." City Engineer Rust reported that the engineers had met in conference to apportion the charge. The total cost would be $365,223. Of that share, Saanich should bear $52,221 and Esquimalt $28,500, the engineers recommended. However, the only fair division was on a percentage basis, they held, under which the Saanich district would pay 14.3 per cent., Esquimalt 7.8 per cent., and Victoria 77.9 per cent. Esquimalt considered it should only pay the percentage to Hereward road, but the city engineer pointed out that if Esquimalt had to build a sewer itself the cost would be $125,000.

Winnipeg, Man.—The works and property committee appointed a sub-committee to go fully into the matter of protecting meters against frost and also of lessening the waste of water in city dwellings, and to furnish a report showing how the situation may be remedied.

LIGHT, HEAT AND POWER.

+—**Calgary, Alta.**—The city council has recommended that the contract be given to the SHEET METAL COMPANY for the heating of the new industrial building, should the present city garage be selected as the site by the new industries committee of the council. The tender of the company was submitted for $2,000. Provision was made that in the event of another site being chosen the recommendation could be withdrawn.

+—**Calgary, Alta.**—The contract has been awarded to ROBERT McCULLOUGH at $990 for the installation of the heating plant in the new pumping station at Calgary.

Dundas, Ont.—The town council has empowered the mayor and clerk to sign a contract between the town and Hydro-Electric system for from 275 to 300 street lights of 100 watts each, at $9 each, to be installed in accordance with the specifications presented by the commission to the council.

Edmonton, Alta.—An important motion which was unanimously adopted by the city council, deals with the extension of the city power plant; and it was also recommended that the commissioners begin at once with the work of having plans and specifications made, tenders called, and contracts awarded.

Guelph, Ont.—The Light and Heat Commission has decided to purchase and install in the new gas and electric light building on Huskisson Street a new gas heating outfit. The object is to give a thorough trial to the use of gas for heating, and if found by the commission and citizens to be a feasible thing to use in private homes, services will be installed in city dwellings.

Guelph, Ont.—Tenders will be received up till October 28th, 1913, for the heating and plumbing of the new dining hall and poultry building at the Ontario Agricultural College, Guelph. Plans and specifications may be obtained from H. F. McNaughten, Esq., Secretary, Department of Public Works for Ontario, Toronto, Ont.

Hamilton, Ont.—Engineer Sifton of the Hydro department has asked the city board of control for a further grant of $335,000 with which to complete the installation of the municipal power plant. Since the original estimate has been made upon the plant, many new streets have been opened, requiring more lamps and far greater sub-station equipment. A by-law will be submitted to the ratepayers in January, 1914.

+—**Montreal, Que.**—A contract for a 450 h.p., 250 r.p.m., 550 volt, 25 cycle, slip-ring type induction motor, with short circuiting and brush lifting device, and pedestal bearings, together with a Siemens type liquid starter, has been placed with the SIEMENS COMPANY OF CANADA by the Dome Mines Company, Limited of South Porcupine. The motor is to be used to drive a compressor made by Belliss and Morcom.

Ottawa, Ont.—Tenders will be received up till November 4th, 1913, for the furnishing and installing of the electric wiring systems required in connection with the equipment of the National Transcontinental Railway car shops at Transcona, Man. Plans and specifications may be obtained from P. E. Ryan, Secretary of the Commissioners of the Transcontinental Railway, Ottawa, Ont.

EUGENE F. PHILLIPS Electrical Works, Limited

MONTREAL - = = CANADA

Branches: HALIFAX TORONTO WINNIPEG VANCOUVER

Owen Sound, Ont.—The electric light and power committee of Owen Sound has reached a decision whereby the town will take 1,200 horsepower from the Hydro-Electric Commission, the energy to be generated at the commission's proposed station at Eugenia Falls. The current will be supplied at $29 per horsepower. Plans have been prepared, and all that remains to bind the contract is the formal signature on the part of the town, since the ratepayers passed a by-law to secure the power nearly two years ago.

Saskatoon, Sask.—Supplying power to the industries located at Factoria, and to the government elevator, has been considered by the city council. To the elevator, it granted a two-cent per kilowatt-hour rate, provided the government will make an agreement with the city. The question of constructing a power line to Factoria was left in the hands of the finance committee and the commissioners with power to act.

Welland, Ont.—The Canadian Niagara Power Company is planning to more than double the original generating capacity of their plant. The plant consisted originally of five units of 10,000 horsepower capacity each. Two additional units of 12,500 horsepower each were installed, and three more are to be placed in position within the next three years. Already an order has been placed for unit No. 8, and the steel sections of the machine will arrive next spring. When the work of installing No. 8 is begun, an order will be given for unit No. 9.

Winnipeg, Man.—Tenders will be received up till November 4th, 1913, for the manufacture and delivery at the Power House of Point du Bois, of electrically operated switching gear and accessories. Plans and specifications may be obtained from M. Peterson, Esq., Secretary, Board of Control, Winnipeg, Man.

BRIDGES, ROADS AND PAVEMENTS.

Brandon, Man.—Representatives from the men's associations are to be appointed to the committee which has been formed to wait upon Superintendent McHarg, of the C.P.R. in regard to an overhead bridge or a subway from the south to the north side of the track in the vicinity of the round-house. Little hope is entertained that the company will build either construction, unless it is compelled to do so by the board of railway commissioners, though the committee will make every effort to have the company build a "slope way" from the First Street bridge on the north side in an easterly direction.

Calgary, Alta.—The city commissioners have approved a plan prepared by Parks Superintendent Reader which calls for an extensive system of boulevarding streets, and for which a local improvement by-law for $150,000 will be submitted to ratepayers. Before this is done, however, the list of streets for which boulevarding is proposed, is to be revised.

Edmonton, Alta.—Plans have been made for a subway on Athabasca Avenue at one of the most dangerous C.P.R. crossings in the city. These plans have to be approved in Ottawa, and copies forwarded from the Dominion Government to the C.P.R. headquarters at Montreal.

Fort William, Ont.—To make the approach from the city side to the bascule bridge adequate and suitable, it has been suggested that a spiral loop which would form an approach to the public traffic of the bridge, and which would reach the street level on the river side of Syndicate Avenue where traffic could move in either direction without loss of time, would meet with all demands.

Hull, Que.—A special meeting of the city council was held and a decision was made to accept the temporary loan of $11,000 offered by the Quebec Provincial Government for the construction of the new macadamized road between Hull and Gatineau Point. The construction work is to be commenced at once.

+—Montreal, Que.—The contract has been awarded to JOHN S. METCALF COMPANY, LIMITED, constructing engineers, Montreal and Chicago, by the Canadian Pacific Railway Company, for the construction of the Glen Arch at Westmount, Montreal, Que. to provide for a width of four tracks. The estimated cost was $50,000.

Montreal, Que.—Mr. McLeod, railway engineer of the city, has submitted to the board of control his plan for the reconstruction of the Ontario Street subway. Mr. McLeod proposes to widen the subway on the north side only and in such a way as to make the width between abutments 60 feet instead of 40 as at present; the head room to be 14 feet instead of 12; under which scheme the total cost of the subway would be approximately $117,000, instead of $153,000 as by the C.P.R. plan. The sewers and water mains can remain as at present, the present abutment and retaining walls will remain intact saving expense and no cross street will be affected by the new grade, except the north-east corner of Ontario and Beaufort, where the existing roadway will have to be lowered about 18 inches. Only $8,000 extra land will have to be acquired for the widening of the street to 60 feet. No decision will be reached by the controllers until the matter has been fully discussed with the Canadian Pacific authorities; and if the plan is adopted by them, application will be made immediately to the Board of Railway Commissioners for the authorization to rebuild the subway.

Vancouver, B.C.—The proposed extension of Venables Street to Campbell Avenue met with a heated discussion at the Grandview Ratepayers' Association meeting. Decision in the matter was deferred for two weeks in order to allow Alderman Evans and Alderman McSpadden time for the preparation of more data with regard to their respective plans for a continuous thoroughfare to Grandview from the East End.

Vancouver, B.C.—The Department of Public Works at Ottawa has approved the plans for the proposed North Vancouver subway under the C.P.R. Company's tracks at the foot of Columbia Avenue to the ferry wharf. The work is to be proceeded with at once, the estimated cost being $35,000.

Vancouver, B.C.—The matter meeting with most recent consideration by the civic bridges and railway committee was the question of the viaducts on Hastings, Pender, Harris, and Keefer Streets. Work upon these structures, it is hoped, will be started this year.

Vancouver, B.C.—The city engineer has recommended to the board of works at an estimate of $10,140 the opening of Carnaron Street to a width of 66 feet northward from a point 61.9 feet north of Tenth Avenue to Broadway. Before the city council can act, however, financial arrangements must be assured.

Victoria, B.C.—At the recent meeting of the Inner Harbor Association, a resolution was passed urging that the Point Ellice bridge be opened, and that the city consent to the sale of a span entrance on the east side to the C.N.P. in connection with the project to raise the bridge level and in its place to substitute a draw span to permit of the opening of the Upper Harbor to navigation. As an obstruction to navigation, the Rock Bay bridge was also referred to, and the straightening of the structure so as to connect with Rock Bay Avenue was urged. It was proposed to fill in the two ends and to place in the centre a draw span which would give access to the two mills on the waterfront east of the bridge, and it was decided to ask the Dominion Government to dredge the area inside.

Winnipeg, Man.—When the C.P.R. has completed its work of raising the track levels and of extending the main shed, alterations will be made to the C.P.R. subway on Main Street. Plans have been approved by the city engineer, and have been submitted to the works and property committee. These have been made in accordance with the agreement made between the city and company early in the summer, and have been accepted by the committee.

INDUSTRIAL WORKS.

Chippewa, Ont.—The committee which was delegated to wait upon the Hon. Dr. Reid at Ottawa to urge the location of a lock at Chippewa, and of the peace memorial bridge at Niagara Falls, reported upon their return that the contract for that section of the new Welland Canal which lies between Welland and Port Robinson, would not be let until engineers had made a complete survey and estimate of the cost of the proposition.

Cote St. Paul, Que.—The Montreal Light, Heat and Power Company are calling for tenders for extensions to their gas works.

700 BULLITT BUILDING, PHILADELPHIA, Pa.

Fort William, Ont.—Tenders will be received up till October 24th, 1913, for plumbing in several houses. Plans and specifications may be obtained from M. McCulloch, Manager, City Clerk's Office, Fort William, Ont.

Fort William, Ont.—The city council has appointed a committee to act in conjunction with a board of trade committee to consider the improvement of conditions at the city dock and the subway leading to it under the C.P.R. tracks.

▲—**Halifax, N.S.**—Tenders will be received up till October 25th for the construction of about 6,500 lineal feet of quay wall, foundations for buildings, sewers, dredging, and filling of reclaimed areas. Plans and specifications may be obtained from L. K. Jones, Assistant Deputy Minister and Secretary, Department of Railways and Canals, Ottawa, Ont.

Hamilton, Ont.—The SMART-TURNER MACHINE CO., LIMITED, of Hamilton, is supplying the Otis Fensom Elevator Co., Limited, with one of the Underwriter fire pumps.

+—**Malbaie, Gaspe Co., Que.**—The contract for building the big new Government pier at Malbaie, Gaspe, has been awarded to JOHN BURNS, at a cost of $42,700.

Merlin, Ont.—Tenders will be received up till October 25th for the repair and improvement of Indian Creek Drain in the Township of Raleigh, city of Chatham, and Township of Harwick. Plans and specifications may be obtained from A. E. Robinson, clerk of Raleigh, and Geo. A. McCubbin, C.E. Signed, Jas. Wellwood, Reeve, (Raleigh Tp.), Merlin, Ont.

Montreal, Que.—The SMART-TURNER MACHINE CO., LIMITED, of Hamilton, is supplying the Harbor Commissioners of Montreal with one of their Simplex power pumps.

Ottawa, Ont.—Tenders will be received up till October 31st, 1913, for Nassau Dam, Trent Canal. Plans and specifications may be obtained from L. K. Jones, Esq., Assistant Deputy Minister and Secretary, Department of Railways and Canals, Ottawa, Ont.

Ottawa, Ont.—Tenders will be received up till November 17th, 1913, for the construction of harbor improvements at Port Hope, Ont. Plans and specifications may be obtained from the District Engineer, J. G. Sing, Esq., Confederation Life Building, Toronto. Signed, R. C. Desrochers, Secretary, Department of Public Works, Ottawa, Ont.

Ottawa, Ont.—The damming of Chippewa Creek, so as to connect the city of Niagara Falls with the new Welland Canal, is being urged upon the Department of Railways and Canals. The creek enters the Niagara River within a mile of the city, and from the outlet to the new canal is a distance of about seven miles. A dam would make the creek navigable and would furnish Niagara Falls with water transportation.

Ottawa, Ont.—Tenders will be received up till November 17th, 1913, for the construction of a pile protection work at Rainy River, Thunder Bay and Rainy River District, Ont. Plans and specifications may be obtained from F. G. Harcourt, Esq., District Engineer, Port Arthur, Ont. Signed, R. C. Desrochers, Secretary, Department of Public Works, Ottawa.

Ottawa, Ont.—Tenders will be received up till November 12th for the construction of a wharf at Rocky Point, West River, Queen's County, P.E.I. Plans and specifications may be obtained from W. E. Hyndman, Esq., District Engineer, Charlottetown, P.E.I. Signed, R. C. Desrochers, Secretary, Department of Public Works, Ottawa, Ont.

Port Moody, B.C.—The city engineer's department is conducting surveys in the neighborhood of Noon and Scott Creeks, on the north side of Burrard Inlet, with a view to locating a source of water supply for the city. Already the Coquitlam municipal council has an application on file for rights on Scott Creek, but will be asked to withdraw in favor of Port Moody.

+—**Salmon River, N.B.**—The contract has been awarded the ISLAND DREDGING COMPANY for the construction of a pier at Salmon River, N.B. The contract price was $9,989.

South Vancouver, B.C.—The organization of the North Arm Harbor Commission has been completed, and the task of improving the north arm of the river is being set in operation. The first features of the work to be undertaken will be the dredging and the construction of the jetty, both of which will require expenditures of thousands of dollars. It has been proposed to build an abutment along the north bank of the arm and to fill in behind this with the mud and silt dredged from the bed of the channel.

St. John, N.B.—The city has had forcibly brought to its attention the inadequacy of its wharves through the withdrawal of the mail steamers. The Board of Trade and the civic authorities are already considering plans to increase greatly the city's wharfage facilities. Two wharves are now under construction on the west side of the harbor and the city government will urge that such contracts as are necessary will be awarded to provide for three additional wharves comprising four berths for use during the winter of 1914-15. A suggestion is also being made that the property be secured, and suitable buildings constructed, for passenger traffic.

▲—**Toronto, Ont.**—Tenders will be received up till November 18th, 1913, for the supplying and laying of an 84-inch steel conduit from the Pure Water Reservoir on Toronto Island, to the South Tunnel Shaft. Plans and specifications may be obtained from the Department of Public Works, Room 10, City Hall, Toronto. Signed, H. C. Hocken (Mayor), Chairman, Board of Control

▲—**Toronto, Ont.**—Tenders will be received up till November 18th for sundries, including brass work, iron and lead pipe, iron valve, special castings, etc. Plans and specifications may be obtained from the head office of the Department of Works, City Hall, Toronto. H. C. Hocken (Mayor), Chairman, Board of Control.

Vancouver, B.C.—Tenders will be received up till October 24th, 1913, for the construction of a 260 cubic yard dump scow. Plans and specifications may be obtained from J. L. Nelson, Esq., Superintendent of Dredges, Department of Public Works, Vancouver, B.C.

Vancouver, B.C.—The ratepayers are to be called upon for the approval of a by-law to raise a loan of $40,000 for a new wharf.

Vancouver, B.C.—The contract for the dredging of the inlet off Pier A will soon be awarded by the C.P.R. Company. Extensive improvements are to be made around the pier for the better accommodation of the deep draft transpacific liners.

Vancouver, B.C.—Tenders will be received up till October 24th, 1913, for the supply of iron work for dump scow. Plans and specifications may be obtained from J. L. Nelson, Esq., Superintendent of Dredges, Department of Public Works, Vancouver, B.C.

+—**Vancouver, B.C.**—The contract has been awarded to the B. C. MARINE RAILWAYS, Esquimalt, for the equipment of the Dominion dredge "King Edward" with an oil-burner.

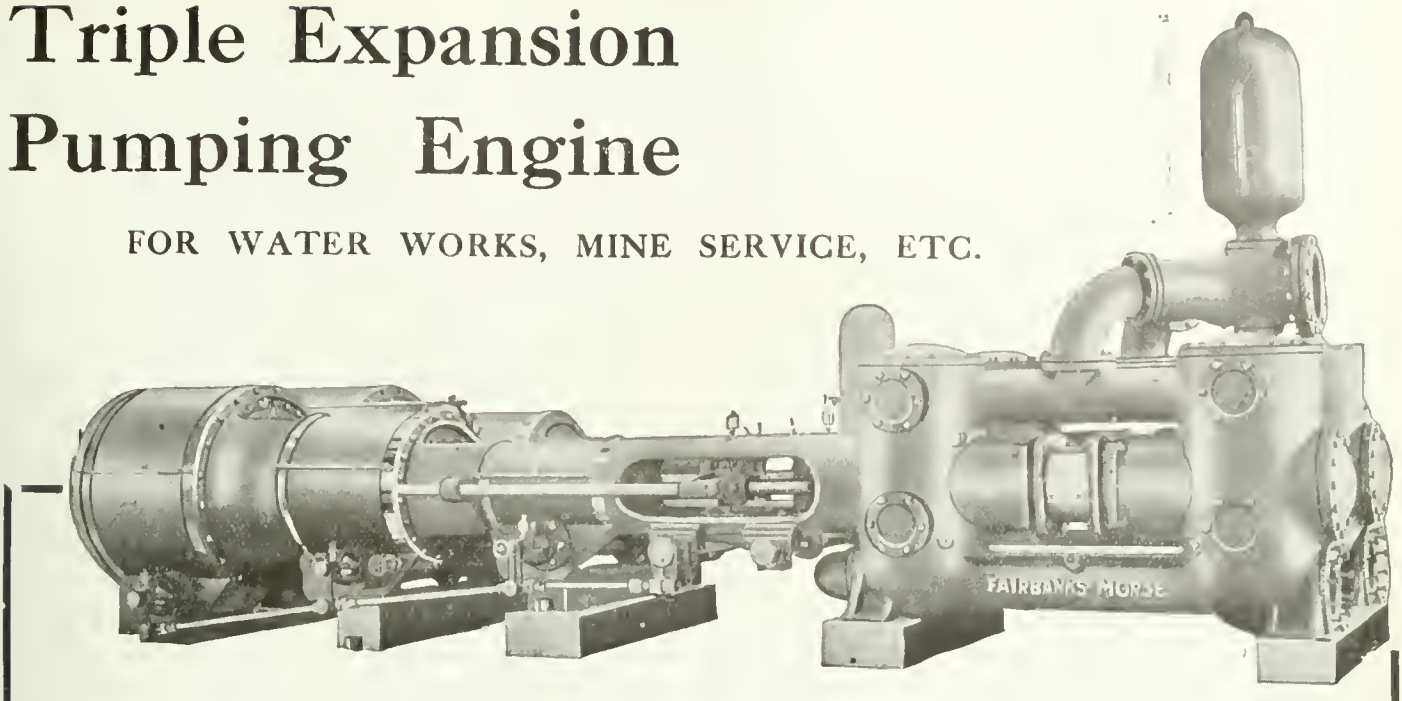
Vancouver, B.C.—The best location and plan for the retaining wall across False Creek, west of Main Street bridge, which is to be built by the Canadian Northern Railway, is being considered by a committee comprised of Mayor Baxter, Ald. Frank E. Woodside, chairman of the bridges and railways committee, Mr. H. H. Stevens, M.P., and members of the harbor commission. The C.N.R. officials are anxious to proceed with the construction as soon as possible.

Victoria, B.C.—The delay in the letting of contracts for the construction of two piers in the vicinity of Ogden's Point, has been explained by a cable from the Hon. R. Rogers. The Minister of Public Works has been recommending piers of stone and cement, instead of piers of crib work with cement covering, as originally planned. The result is that call for tenders for stone and cement piers is expected within a few days.

Winnipeg, Man.—The Harbor Commission have decided upon the construction of a large public dock, 500 feet in length, on the Winnipeg bank of the Red River, between James and Pacific avenues. Plans have been completed at an estimated cost of $35,000, but the construction cannot be begun until a grant is forthcoming from the Dominion Government.

Triple Expansion Pumping Engine

FOR WATER WORKS, MINE SERVICE, ETC.



The Fairbanks-Morse Triple Expansion Duplex Outside Centre Packed Plunger Pumping Engine shown here is very economical in the consumption of steam. The economy of operation makes this Pump preferable to all others in many situations.

The steam end is fitted with semi-rotative valves. The plungers being externally packed are always in sight and any leakage can be at once detected.

All parts are easy of access. The stuffing boxes are large and deep, so that ample allowance of packing may be used.

This type of pump is heavily proportioned throughout in order to meet the demands of heavy service. It is designed to give long and satisfactory service at a minimum cost. It has a 24-inch stroke and a capacity of 2,500,000 gallons per 24 hours.

Departmentalising a Great Business

The marketing of one article is a very simple problem. As the number and variety of the products you sell increase, the complexity of your merchandising problem grows.

Our business has grown in the last dozen years from a comparatively few products into an enormous number of lines. This tremendous growth has necessitated the organizing of our business along departmental lines with able, efficient men at the heads of the various departments.

As organized now we can serve the mechanical field better than any house in Canada. In addition to being manufacturers, we are literally a large "departmental house for machinery and mechanical goods." This bringing together of a vast number of lines and classifying them according to departments is the kind of combination in industry that makes for efficiency, economy and better service.

It is just as great a convenience to Engineers, Contractors and Builders to be able to get their supplies from one House as it is to the general public to shop in a large, modern department store. In dealing with us you can get what you want "under one roof." Write, phone or call.

The Canadian Fairbanks-Morse Co., Limited

TENDERS CALLED FOR

SPECIAL NOTICE TO CONTRACTORS.

RE GREATER WINNIPEG WATER SUPPLY.

(Estimated Cost $13,500,000.)

Notice is hereby given to Contractors that tenders will be invited early in the year 1914 for the construction of works necessary for the delivery of water from Shoal Lake to the Greater Winnipeg Water District. The following is a brief description of the proposed works:—

1. A dyke and channel for the diversion of the Falcon River into Snowshoe Bay.
2. 85 miles concrete aqueduct.
3. 10 miles pipe line (probably 1916 work).
4. 900 lineal feet tunnel under Red River.
5. 85 miles of construction railway.
6. Telephone line.
7. Clearing and ditching.

The fall season of the year affords the best opportunity for inspection of proposed route of the aqueduct, and it is recommended that contractors having a view to tendering on the work should send their inspectors over the line at as early a date as possible.

Particulars as to estimated cost of the work and map of approximate location and profile of aqueduct may be obtained from the undersigned.

M. PETERSON,
Acting Secretary of the
Administration Board,
Greater Winnipeg Water
District.

City Hall,
Winnipeg, Canada,
October 6th, 1913.

Note.—Copy of report of the Consulting Engineers, plan and profile of work and typical details of design may be seen at the office of *The Canadian Engineer*, 62 Church Street, Toronto.

NOTICE TO CONTRACTORS.

Tenders will be received by registered post only, addressed to the Chairman of the Board of Control, City Hall, Toronto, up to noon, on **Tuesday, November 4th, 1913,** for the construction of the following sewers:—

Division No. 2, West Toronto, Contract No. 3.

Outlet from Keele Street and Uttley Park to Quebec and Annette, via Uttley Park, Hillsview Avenue, Medland Crescent, Humberside Avenue and Quebec Avenue.

Envelopes containing tenders must be plainly marked on the outside as to contents.

Specifications may be seen, and forms of tenders obtained at the office of the Commissioner of Works, Toronto.

Tenderers shall submit with their tender, the names of two sureties (approved by the City Treasurer, not members of the City Council, or officers of the Corporation of the City of Toronto) or in lieu of said sureties, the bond of a guarantee company, approved of as aforesaid.

The usual conditions relating to tendering as prescribed by the City By-law must be strictly complied with.

The lowest or any tender not necessarily accepted.

H. C. HOCKEN (Mayor),
Chairman, Board of Control.

Toronto, October 15th, 1913.

Sealed tenders addressed to the undersigned, and endorsed "Tender for Addition and Alteration to Public Building, Lindsay, Ont.," will be received at this office until 4 p.m., on Wednesday, November 5, 1913, for the work mentioned.

Plans, specification and form of contract can be seen and forms of tender obtained at the office of Mr. Thos. Hastings, Clerk of Works, Postal Station F, Yonge Street, Toronto, at the Post Office, Lindsay, Ont., and at this Department.

Persons tendering are notified that tenders will not be considered unless made on the printed forms supplied, and signed with their actual signatures, stating their occupations and places of residence. In the case of firms, the actual signature, the nature of the occupation, and place of residence of each member of the firm must be given.

Each tender must be accompanied by an accepted cheque on a chartered bank, payable to the order of the Honorable the Minister of Public Works, equal to ten per cent. (10 per cent.) of the amount of the tender, which will be forfeited if the person tendering decline to enter into a contract when called upon to do so, or fail to complete the work contracted for. If the tender be not accepted the cheque will be returned.

The Department does not bind itself to accept the lowest or any tender.

By order,

R. C. DESROCHERS,
Secretary.

Department of Public Works,
Ottawa, October 15, 1913.

Newspapers will not be paid for this advertisement if they insert it without authority from the Department.—47381.

Sealed tenders addressed to the undersigned, and endorsed "Tender for Harbor Improvements at Port Hope, Ont.," will be received at this office until 4 p.m., on Monday, November 17, 1913, for the construction of Harbor Improvements at Port Hope, Durham County, Ontario.

Plans, specification and form of contract can be seen and forms of tender obtained at this Department and at the office of J. G. Sing, Esq., District Engineer, Confederation Life Building, Toronto, Ont., and on application to the Postmaster at Port Hope, Ont.

Persons tendering are notified that tenders will not be considered unless made on the printed forms supplied, and signed with their actual signatures, stating their occupations and places of residence. In the case of firms, the actual signature, the nature of the occupation, and place of residence of each member of the firm must be given.

Each tender must be accompanied by an accepted cheque on a chartered bank, payable to the order of the Honorable the Minister of Public Works, equal to ten per cent. (10 per cent.) of the amount of the tender, which will be forfeited if the person tendering decline to enter into a contract when called upon to do so, or fail to complete the work contracted for. If the tender be not accepted the cheque will be returned.

The Department does not bind itself to accept the lowest or any tender.

By order,

R. C. DESROCHERS,
Secretary.

Department of Public Works,
Ottawa, October 16, 1913.

Newspapers will not be paid for this advertisement if they insert it without authority from the Department.—47820.

(For further Tenders see page 88.)

Insuring Pumps

against their destruction by fire requires engineering knowledge that is not needed in insuring dwellings, stores, etc.. We used the word "Pumps" only as an illustration. It requires sound engineering and expert insurance knowledge—combined in the one firm—to secure for any industrial or engineering firm the lowest possible insurance rates. Only a firm like ours—employing a staff of engineers—could appreciate your requirements—not only in fire insurance but also in special forms of insurance.

Structural Details of Hip and Valley Rafters.

By CARLTON THOMAS BISHOP, C.E., Assistant Professor of Civil Engineering, Yale University. Oblong 4to, fully illustrated by general drawings and typical problems, vi+72 pages. Cloth, $1.75 net.

This book has been written to meet the requirements of structural draftsmen when solving problems in hip and valley construction. Complete directions are given for making shop drawings for the steel work of intersecting roofs and similar structures. The notes for the various cases are arranged for convenient reference and are illustrated by general drawings and typical problems.

Graphics and Structural Design.

By H. D. HESS, M.E., Professor of Machine Design, Sibley College, Cornell University. Formerly Designer and Computer for the Mechanical Department of the Pencoyd Iron Works and the American Bridge Company. Member, American Society of Mechanical Engineers. 8vo, viii+426 pages, 429 figures. Cloth, $3.00 net.

To the general designer knowledge of this subject is indispensable while acquaintance with the methods used in determining the stresses in, and the subsequent designing of, structures is of the greatest benefit to others in all designing for strength, whether of machines or structures.

A Treatise on the Design and Construction of Roofs.

By N. CLIFFORD RICKER, B.S., M. Arch., D. Arch., Professor of Architecture, University of Illinois. 8vo, xii+432 pages, 644 figures. Cloth, $5.00 net.

Supplies the data, methods, formulas, and tables required in the design of a roof, arranged in the simplest manner and so as to require the least time and labor in their application.

Applied Methods of Scientific Management.

By FREDERICK A. PARKHURST, M.E., Associate, American Society of Mechanical Engineers. 8vo, xii+325 pages, 48 figures, and 9 plates. Cloth, $2.00 net.

This book will appeal strongly to the manager or superintendent of a plant, as it contains valuable suggestions and outlines the routine which should be assigned to almost every employee.

Elements of Heating and Ventilation.

By ARTHUR M. GREENE, Jr., Professor of Mechanical Engineering, Rensselaer Polytechnic Institute. 8vo, vi+324 pages, 223 figures. Cloth, $2.50 net.

Brings together in logical order and in a small volume the necessary data from which to design the heating and ventilating systems of buildings.

TENDERS CALLED FOR

TENDERS FOR 84-IN. STEEL CONDUIT.

Tenders will be received by registered post only, addressed to the Chairman of the Board of Control, City Hall, Toronto, Canada, up to noon on

Tuesday, November 18th, 1913,

for the supplying and laying of an 84-inch steel conduit from the Pure Water Reservoir on Toronto Island to the South Tunnel Shaft.

Specifications and tender forms may be obtained upon application at the Department of Works, Room 10, City Hall, Toronto.

Envelopes containing tenders must be plainly marked on the outside as to contents. Conditions relating to tendering, as prescribed by city by-law, must be strictly complied with, or the tenders may be declared informal. Tenderers shall submit with their tenders the names of two personal sureties approved by the City Treasurer, or in lieu thereof, the bond of a guarantee company, approved as aforesaid.

The lowest or any tender not necessarily accepted.

H. C. HOCKEN (Mayor),
Chairman, Board of Control.

City Hall, Toronto, October 17, 1913.

TENDERS FOR ANNUAL SUPPLIES.

DEPARTMENT OF WORKS.

TENDERS will be received by registered post only, addressed to the Chairman of the Board of Control, City Hall, Toronto, Canada, up to noon on Tuesday, November 18th, 1913, for: —

BRASS AND BRONZE CASTINGS.
BRASS WORK FOR HOUSE SERVICES.
CAST IRON PIPES.
HYDRANTS.
IRON VALVE AND STOP COCK BOXES.
LEAD PIPE.
SPECIAL CASTINGS.
STOP VALVES.

Specifications and tender form for any of the foregoing may be obtained upon application at the Head Office of the Department of Works, City Hall, Toronto. Envelopes containing tenders must be plainly marked on the outside as to contents. Conditions relating to tendering as prescribed by City By-law, must be strictly complied with, or the tenders may be declared informal. Tenderers shall submit with their tenders the names of two personal sureties, approved by the City Treasurer, or in lieu thereof, the bond of a guarantee company approved as aforesaid.

The lowest or any tender not necessarily accepted.

H. C. HOCKEN (Mayor),
Chairman, Board of Control.

City Hall, Toronto,
October 21st, 1913.

MAIL CONTRACT.

Sealed tenders addressed to the Postmaster-General, will be received at Ottawa until noon on Friday, the 14th November, 1913, for the conveyance of his Majesty's mails, on a proposed contract for four years, six times per week each way, over Mono Road and Rural Mail Route, from the Postmaster-General's pleasure.

Printed notices containing further information as to conditions of proposed contract may be seen and blank forms of tender may be obtained at the Post Office of Mono Road, and at the office of the Post Office Inspector, Toronto.

A. SUTHERLAND,
Post Office Inspector.

Post Office Inspector's Office, Toronto, October 7th, 1913.

52 A.—2,500-26 9-12.

FURTHER EXTENSION OF TIME.

DEPARTMENT OF RAILWAYS AND CANALS, CANADA.

CANADIAN GOVERNMENT RAILWAYS.

Halifax Ocean Terminals Railway, Halifax, N.S.

Sealed tenders addressed to the undersigned and endorsed "Tender for docks, First Unit, Contract No. 3, Halifax Ocean Terminal," will be received at this office until twelve o'clock noon, Saturday, the twenty-fifth day ot October, 1913, for the construction of about 6,500 lineal feet of quay wall, foundations for buildings, sewers, dredging of harbor to a depth of 45 feet at low water, and filling reclaimed areas.

Plans and specifications and form of tender may be seen and full information obtained at the office of the General Manager, Moncton, N.B., at the office of the Chief Engineer of the Department of Railways and Canals, Ottawa, and at the office of the Superintending Engineer, Halifax, N.S.

The right is reserved to reject any or all tenders.

By order, L. K. JONES,
Assistant Deputy-Minister and Secretary,

Department of Railways and Canals,
Ottawa, September 2nd, 1913.

(For further Tenders see page 84.)

CURRENT NEWS.

Ottawa, Ont.—The Minister of the Interior purposes making an investigation into the small water powers in the West, and he has sent out an engineer with this end in view. The development of these powers is to be encouraged, and recently the regulations regarding the leasing of such powers were amended.

Ottawa, Ont.—The drill in Dundonald Park has failed to strike water after reaching a depth of 1,130 feet; but permission has been granted the firm in charge of boring operations to proceed to a depth of 2,000 feet. After this depth has been reached, if the operations are still unsuccessful, further attempts to locate a subterranean stream for well purposes will be abandoned.

PANAMA CANAL EQUIPMENT FOR SALE.—The Isthmian Canal Commission will offer for sale in the near future the equipment used in building the Panama Canal, such as rolling stock, excavating machinery, floating equipment, miscellaneous plants, and miscellaneous equipment, including locomotives, cars, steam shovels, cranes, unloaders, earth spreaders, track shifters, rock drills, well drills, dredges, barges, tugs, launches, pile drivers, concrete handling plants, pumps, rock crushers, etc. Inquiries from users of such equipment are invited for its purchase. Catalogues listing the equipment offered for sale and other information may be obtained upon application to the General Purchasing Officer, Isthmian Canal Commission, Washington, D.C. F. C. Boggs, Major, Corps of Engineers, U.S.A., General Purchasing Officer.

FOR SALE.—One model 41 Marion steam shovel, less than a year old; one Porter locomotive; ten 4-yard Western cars; one 40 H.P. boiler. Please address Box 154, *The Canadian Engineer*, Toronto.

MISCELLANEOUS.

Calgary, Alta.—Great expectations are entertained with regard to the oil fields near Okotoks, Alta. Private messages have been received to the effect that the oil strikes made give promise of very great supply.

Edmonton, Alta.—The city commissioners recommended to the council that an expenditure be authorized for the construction of gates to protect pedestrians and traffic at railway crossings on four of the city's streets. The recommendation was accepted unanimously, and the gates, including proper signs and lights, will be established at the earliest possible date.

+—Fredericton, N.B.—The contract for the new I.C.R. freight sheds in Fredericton has been awarded to MESSRS. McLAGGAN, McBEAN AND BELL of this city. The contract price is said to be between $13,500 and $15,000.

Goderich, Ont.—The American Road Machinery Company proposes to erect very shortly an addition to their factory at Goderich, which will be a building 70 x 100 feet.

+—Montreal, Que.—Wright and Sons, architects of Montreal, have awarded the general contract for the new G. R. Prowse Range Company's building, on University Street, to ROBERT NELVILLE of Montreal. The contract for the steel work has been awarded to the DOMINION BRIDGE COMPANY, and the excavation, concrete and brickwork to A. E. WAND.

▲—Ottawa, Ont.—Tenders will be received up till November 5th, 1913, for addition and alteration to a public building, Kingston, Ont. Plans and specifications may be obtained from R. C. Desrochers, Secretary of Public Works, Ottawa, Ont.

+—Ottawa, Ont.—The Government of Canada has let contracts necessary for the installation of a $90,000 telescope; and this is to be completed in less than two years. Canada will possess then the largest reflecting telescope in the world. WARNE AND SWASEY of Cleveland, will supply the mechanical equipment; and the JOHN A. BRASHEAU COMPANY of Pittsburg, the lenses. These latter will include a 6-foot silvered mirror, which will take almost a year to manufacture. The probable location of the telescope will be at the Dominion Observatory at the Experimental Farm.

Ottawa, Ont.—Application for incorporation has been made to the Secretary of State's Department by the Confederation Contracting Company, Limited. The new firm is to be capitalized at $2,000,000; and it is understood that it will act this winter as sub-contractor on the Welland Canal.

Ottawa, Ont.—The Canadian Government has retained in its service the firm of Vitale and Rothery, forest engineers of New York City, to advise with the Canadian Conservation Commission in planning the survey of the Crown lands in the Province of New Brunswick.

Petitcodiac, N.B.—A movement is on foot for the rebuilding of the burnt district at Petitcodiac with concrete. In consideration of that a delegation has visited Moncton to ascertain the cost of cement blocks and to investigate all necessary matters connected with rebuilding.

Quebec, Que.—The C.P.R. Company has announced its decision to re-erect a large modern passenger station in the city of Quebec. The new structure will be commenced in the spring. A further project is to use the old Champlain Market as a freight station, complementary to the new construction.

Regina, Sask.—Mr. E. A. Brown, Regina, has invented a tube bender for conduit work. This is the third appliance which Mr. Brown has invented for conduit work.

Rideau Junction, Ont.—The construction of the C,N,R, shops at Rideau Junction has commenced, and an endeavour will be made to have them completed by the coming spring. It is expected that these shops will be eventually the largest and most important on the C.N.R. system.

CURRENT NEWS.

Edmonton, Alta.—The special committee appointed by the council to investigate the reduction of power charges, have reported to the council, but have reached as yet no definite conclusions. The committee reports thus:—"Having gone very carefully into the question of the rates at present being charged the street railway department and electric light department, by the power house department, we believe that a better arrangement ought to be entered into with these two departments, and we would recommend that a committee consisting of Messrs. Ormsby, Parsons and Woodroofe be appointed to go into the whole question of rates, and report to the council at its next session."

Hamilton, Ont.—Engineer Geoffrey of the Hydro-Electric Commission has inspected the township for the purpose of furnishing to the commission and to the Reeve of the township an estimate of the cost of lighting this area with hydro light.

Howick, Que.—The village of Howick is spending over $10,000 this year in the construction of macadamized roadways for its central streets, and all the work is to be completed before winter sets in.

Montreal, Que.—A report has been given the city legislation committee by Dr. Louis Laberge, in which he urges that power be secured from the Legislature permitting the city not to take over a new street until sewers, water-pipes, gas-pipes, and wire conduits are underground, and sidewalks and macadam or pavements are laid. This reform, he claims, is greatly in the interests of public health.

PERMANENCE—

an ideal that is now attainable

THE superiority of concrete over all other materials for the building of permanent structures is now generally admitted.

The next step towards ideal construction, is to realize that for satisfactory concrete work, it is necessary to use a cement that is uniformly high-grade

CANADA Portland CEMENT

is the selection of the leading engineers, architects and contractors. Their experience has proved that in this brand they can obtain a certainty of success.

With concrete coming into more and more general use for the construction of buildings, bridges, viaducts and highways, it is vitally important that those in authority on such matters should select the best materials obtainable.

Use the cement that our best architects and engineers have selected for their most important undertakings. Select Canada Cement — it costs no more than any others.

All communications strictly confidential. Address Box 164, *The Canadian Engineer*, Toronto.

CURRENT NEWS.

Ottawa, Ont.—A conference is to be held in Ottawa on October 30th, which will deal with the pollution of navigable waterways and joint action by the Dominion and the provinces with a view to its prevention. Representatives from the Dominion and the provinces are to attend, and the report of the special committee of the House of Commons, which investigated the question during the last session, will be presented.

St. Catharines, Ont.—The second shovel has been put to work near lock twenty-five on the railroad cut of No. 3 section of the Welland Ship Canal. This is but a start on labor that will ultimately employ 50 shovels or more before its completion.

St. Catharines, Ont.—It is stated that the big trunk sewer, which is to supply Vine Street and the intervening territory between that point and Carleton Street, will be completed within a week. Considerable delay has been experienced in the work due to the discovery of quicksand.

Toronto, Ont.—Work has recommenced on the new G.T.R. bridge at Sunnyside. There has been a delay in the supply of steel, but the difficulty seems to have been circumvented and the large steel spans are now in process of erection.

Vancouver, B.C.—The effort made by the city council to secure a Government loan from the province for continuing the construction of the Marine Drive through to Horseshoe Bay has been unsuccessful. The Minister of Public Works has stated that no further Government appropriations can be made this year, and work on the road must be discontinued for the present.

Victoria, B.C.—Delay is being experienced on the Johnson Street bridge, due to questions of location and grade which cannot be settled until Mr. Gamble, Chief Engineer of Railways, returns, and the matter is again taken up with Government officials.

Welland, Ont.—The first dredge has started work on Contract No. 1 of the Welland Ship Canal at Port Weller. The intention of the contractors is to carry on dredging operations night and day, and to use the material dislodged for the construction of a temporary haven for the protection of the company's fleet of scows, tugs and coal barges during the coming winter.

THE FOUNDATION COMPANY, LIMITED

MONTREAL VANCOUVER

MARKET CONDITIONS

Montreal, October 18th, 1913.

Bar Iron and Steel—Trade is reported active. Bar iron, $2.10 per 100 pounds; best refined horseshoe, $2.35; forged iron $2.25; mild steel, $2.20; sleigh shoe steel, $2.20 for 1 x ⅜ base; tire steel, $2.30 for 1 x ⅜ base; toe caulk steel $3; machine steel, iron finish, $2.25.

Cement—Canadian cement is quotable, as follows, in car lots, f.o.b., Montreal:—$1.35 to $1 40 per 350-lb. bbl., in cotton bags, adding 10c. for each bag. Good bags re purchased at 10c. each. Paper bags cost 2½ cents extra, or 10c. per bbl. weight.

Chain—The market is quoted per 100 lbs. as follows:—¼-in., $5.65; 5/16-in. $4.70; ⅜-in., $4.00; 7/16-in., $3.65; ½-in , $3.45; 9/16-in., $3 45; ⅝-in., $3.35; ¾-in., $3.25; ⅞-in., $3.15; 1 in., $3.05.

Explosives and Accessories—Dynamite, 50-lb. cases, 40 per cent. proof, 15c. in single case lots. Montreal; 50 per cent., 16½c., and 60 per cent., 18c. Blasting powder, 25-lb. kegs, A, $1.85, and B, $2.35 per keg. Special quotations on large lots of dynamite and powder. Detonator caps, case lots, containing 5,000, 75c. per 100; double strength, $1, and broken lots higher; electric blasting apparatus:—Batteries, 1 to 10 holes, $13.50; 1 to 10 holes, $20.50; 1 to 50 holes, $41. Wire, leading, 1c. per foot; connecting, 50c. per lb. Fuses, platinum, single strength, per 100 fuses:—4-ft. wires, $3; double strength, $3.50; 6-ft. wires, $3.54, and double, $4.04; 8-ft. wires, $4.08, and double, $4.58; 10-ft. wires, $5, and double, $5.12.

Galvanized Iron—The market is steady. Prices, basis, 28-gauge, are:—Queen's Head, $4.40; Colborne Crown, $4.20; Apollo, 10¾ oz., $4 30. Add 25c. per 100 lbs. to above figures for less than case lots; 26-gauge is 25c. less than 28-gauge, American 28-gauge and English 26 are equivalents, as are American 10¾ oz., and English 28-gauge.

Galvanized Pipe—(See Pipe, Wrought and Galvanized)

Iron.—Following prices are on dock. No. 1 Summerlee, $22.50 per ton; selected Summerlee, $22; soft Summerlee, $21.50 per ton. No. 3 Middlesboro irons are about $19 per ton. Carron iron number for number and grade for grade is quoted about the same price as Summerlee. Canadian iron sells here at about $19.25 to $19.50 per ton, on track.

Lath—See Lumber, etc.

Lumber, etc.—Prices on lumber are for car lots, to contractors, at mill points. Red pine, mill culls out, $20 to $22 per 1,000 feet; white pine, mill culls, $20. Spruce, 1-in. by 4-in. to 6-in., $21; 1 x 7 to 9, $24 per 1,000 ft.; mill culls, $18. Hemlock log run, culls out, $19. Railway Ties, Standard Railway Ties, hemlock or cedar, 50 to 55c. each. Telegraph poles: seven-inch top, cedar poles, 25-ft. poles, $2, each; 30 ft., $3.75; 35-ft., $4.50 each; 40-ft., $6; 45 to 50, 16c. per foot. Laths: Quotations per 1,000 laths, at manufacturers' points. Spruce 4-ft. x 1½ in., mill run, $3 to $3.25; pine, 4-ft. x 1⅜-in., mill run, $3.25 to $3.75. Shingles: Cedar shingles, same conditions as laths, X, $2.10; XX, $2.40; XXX, $2.80.

Pipe—Cast Iron—The market is dull and rather easy:—$34 for 6 and 8-inch pipe and larger; $35 for 40-inch at the foundry. Pipe, specials, $3 per 100 pounds. Gas pipe is quoted at about $1 more than the above.

Pipe—Wrought and Galvanized—Demand is fair and the market steady: —¼-inch $5.50, with 63 per cent. off for black, and 48 per cent. off for galvanized; ⅜-inch, $5.50, with 63 per cent. off for black, and 48 per cent. off for galvanized; ½-inch, $8.50, with 69 per cent off for black, and 59 per cent. off for galvanized. The discount on the following is 72½ per cent. off for black, and 62½ per cent. off for galvanized; ¾-inch, $11.50; 1-inch, $16.50; 1¼-inch, $22.50; 1½-inch, $27. On the following the discount is 72½ per cent. for black and 62½ per cent. for galvanized:—2-inch, $36; 2½-inch, $57.50, and 3-inch $75.50; 72½ per cent. off for black, and 62½ per cent. off for galvanized: 3½-inch $95 4-inch $1.08.

Fuses—Electric Blasting—Double strength, $3.50 per hundred, advance 54c. per hundred for each 2-in. wire additional. Single strength, $3 per hundred, advance 54c. per hundred for each 2-in. wire additional.

Iron Chain—¼-inch, $5.75; 5-16-inch, $5.15; ¾-inch, $4.15; 7-16-inch, $3.95; ½-inch, $3.75; 9-16-inch, $3.70; 5-8-inch, $3.55; ¾-inch, $3.45; ⅞-inch, $3.40; 1-inch, $3.40 per 100 lbs.

Iron Pipe—Quotations are changed as follows:—Black pipe, ¼-inch, $2.04; ⅜-inch, $2.04; ½-inch, $2.72; ¾-inch, $3.16; 1-inch, $4.54; 1¼-inch, $6.19; 1½-inch, $7.43; 2-inch, $9.90; 2½-inch, $15.80; 3-inch, $20.75; 3½-inch, $26.13; 4-inch, $29.70; 5-inch, $40 60; 6-inch, $52.64. Galvanized Pipe, ¼-inch, $2.86; ⅜-inch, $2.86; ½-inch, $3.57; ¾-inch, $4.31; 1-inch, $6.19; 1¼-inch, $8.44; 1½-inch, $10.13; 2-inch, $13.50; 2½-inch, $21.56; 3-inch, $28.31.

Lead—Firmer, $5.25 to $5.50.

Pig Iron—We quote Clarence at $24 for No. 3; Cleveland, $24; Summerlee, $27; Hamilton quotes $22; Midland, No. 1, $22; No. 2, $21.50. There is considerable enquiry for 1912.

Pitch and Tar—Pitch, unchanged at 75c. per 100 lbs. Coal tar, $3.75 per barrel.

Roofing Slate—Most of the slate used in Canada comes from Pennsylvania or Maine, the Canadian supply being slender and mostly from the Rockland quarries of the Eastern Townships, in Quebec. There is a great variety of sizes and qualities, so that it is difficult to indicate prices. But Jackson Bangor, 10 x 16 may be quoted at $6.75 per square of 100 square feet f.o.b. cars, Toronto; seconds, 50c. less. Mottled, $8; green $8, with a prospect of advance. Dealers are fairly busy.

Sand—Sharp, for cement or brick work, $1.15 per net yard f.o.b., cars, Toronto siding.

Sewer Pipe—

	4-in.	6-in.	9-in.	12-in.	24-in.
Straight pipe; per foot	$0 25	$0.40	$0.65	$1.00	$ 3.25
Single junction, 1 or 2 ft. long	1.00	1.60	2.60	4.00	13.00
Double junctions	1.25	2.00	3.25	5.00	16.25
Increasers and reducers	....	1.60	2.60	4.00	13.00
P. & H. H. traps	2.00	3.20	6.50	15.00	....
Bends	0.75	1.20	1.95	3.00	9.75

Above is the October list as changed. The retail price is less 65 per cent. off these figures on all sizes 9 inches and under, or less 60 per cent. off these figures on anything over 9 inches. For car-loads a greater discount.

Steel Beams and Channels—Active—We quote:—$2.65 to $3 cut to length per 100 lbs., according to size and quantity; angles, 1½ by 3-16 and larger, $2.50 to $2.75; tees, $2 75 to $3 per 100 lbs. Extra for smaller sizes of angles and tees.

Sheet Copper—22c. per lb.

Sheet Steel—American Bessemer, 10-gauge, $2.75; 12-gauge, $2.80; 14-gauge, $2.50; 17, 18, and 20-gauge, $2.75; 22 and 24-gauge, $2.80; 26-gauge, $2.85; 28-gauge, $3. A very active movement is reported at unchanged prices.

Sheets, Galvanized—Apollo Brand—Sheets, 6 or 8 feet long, 30 or 36 inches wide; 10-gauge, $3; 12-14-gauge, $3; 16, 18, 20, $3.30; 22-24, $3,40; 26, $3.50; 28, $3.90; 29, $4.10; 10¾, $4.10 per 100 lbs. Fleur de Lis—28-gauge, $4.25; 26, $4.05 per 100 lbs. Active and firm at these prices.

Tin—The combination seems to hold, and the price, 45 to 50c., lower.

Tool Steel—Jowett's special pink label, 10½c. Cammel-Laird, 16c " H.R.D." high speed tool steel, 65c.

Tank Plates—3-16 inch, $2.40 per 100 lbs.

Zinc—Spelter—Good demand, and the feeling strong. Light stock; excellent demand. We quote very firm at $6 to $6.50 per cwt.

Toronto, October 22nd, 1913.

The following are the wholesale prices for Toronto, where not otherwise explained, although for broken quantities higher prices are quoted:

Axes.—Standard makes, double bitted, $6 to $10; single bitted, per dozen, $7.50 to $9.

Bar Iron—$2.25 base, per 100 lbs., from stock to wholesale dealer. In enormous demand.

Bar Mild Steel—Per 100 lbs., $2.25. Sleigh shoe and other take same relative advance.

Boiler Plates—½-inch and heavier, $2.20. Boiler heads 25c. per 100 pounds advance on plate. Tank plate, 3-16-inch, $2.40 per 100 pounds.

Boiler Tubes—Orders continue active. Lap-welded, steel, 1¼-inch, 10c. 1½-inch, 9c. per 10-ft.; 2-inch, $8.50 to $9; 2¼-inch, $10; 2½-inch, $10.50; 3-inch, $12.10; 3½-inch, $15; 4-inch, $19.

Bricks—In active movement. The price is $11.50 for grey stock, $12 for red stock. Don Valley pressed brick are in request. No. 1 dry pressed and buff bricks are worth $18 delivered and $17 at works per 1,000. Port Credit Brick Company's prices are as follows, f.o.b., Port Credit: Wire cut bricks, $10 per M.; pressed bricks, $14 to $15 per M., three grades.

Broken Stone—Lime stone, good hard, for roadways or concrete, f.o.b., quarries 70 to 75c per ton of 2,000 lbs., either 1-inch, 10c., 2-inch or larger, price all the same. Rubble stone, 55c. per ton, Schaw station, and a good deal moving. Broken granite is selling at $3 per ton for good Oshawa, or Quebec Province. At Washago, $2.50 per ton for small, and $1.15 for large, freight to Toronto 60 cents.

Cement—Demand very brisk, and prices maintained. In large quantities the price is $1.50, sacks, 40c. extra; car lots $1.55, sacks extra; city dealers ask $1.85, sacks extra. Prices remain firm.

Copper Ingot—The market is lower at 15½ to 16c., sheet copper case (16 oz. soft), 22½c. to 24½c. per lb.

Detonator Caps—75c. and $1 per 100; case lots, 5,000, 20 per cent. off.

Dynamite—The prices for this explosive vary according to the percentage of nitro-glycerine compounded in the mixture and are as follows, f.o.b., Toronto:—40 per cent., 16¼ cents per pound, 1 to 9-case lots, 50 lbs. to case. For each additional 10 per cent. nitro-glycerine add 1½c. per hundred. For 10-case lots and over deduct ½ cent. For 20-case lots and over deduct 1 cent. For 40-case lots and over deduct 1½ cents.

Winnipeg, October 21st, 1913.

Anvils—Per pound, 11½ to 12½c.; Buckworth anvils, 80 lbs. and up, 10¼ to 10¾c., anvil and vise combined, each $5.50.

Bar Iron—$2.50 base.

Bars—Crow, $4.50 per 100 pounds.

Beams and Channels—$3 to $3.10 per 100 up to 15-inch, 4, 30, 41, 50, 118, 119, 172, 132, 145, 176.

Brick—Kiln run per M, $13; sewer pipe per M, $14; chimney per M, $14; veneer per M, $15; pressed per M, $25 to $50; enameled per M, $100; sand lime per M, $13.

Cement, Portland—$2.40 to 2.50 per barrel.

Chain—Coil, 3-16-in., $10; ¼, $7.25; 5-16, $5.85; ⅜, $5; 7-16, $4.75; ½, $4.50; 9-16, $4.50; ⅝, $4.40; ¾, $4.25. Logging, 5-16, 6½c.; ⅜, 5¾c. Tie out, 70 and 10 per cent.

Copper—Tinned, boiler, 26½c., planished, 29½c.; boiler and T. K. pits, plain, tinned, 45 per cent. discount.

Dynamite—$11 to per case.

Galvanized Iron—Apollo, 10¾, $4.80; 28, $4.60; 26, $4.20; 22, $4.10; 24, $4.10; 20 $4; 18 $3.95; 16, $3.90. Queen's Head, 28, $4.90; 26, $4.70; 24, $4.30; 22, $4.30; 20, $4.10 per cw

Iron—Swedish iron, 100 lbs., $4.75 base; sheet, black, 14 to 22 gauge, $3.75; 24-gauge, $3.90; 26-gauge, $4; 28-gauge, $4.10. Galvanized—American, 18 to 20-gauge, $4.40; 22 to 24-gauge, $4.65; 26 gauge, $4.65; 28-gauge, $4.90; 30-gauge, $5.15 per 100 lbs. Queen's Head, 22 to 24-gauge, $4.65; 26-gauge English, or 30-gauge American, $4.90; 30-gauge American $5.15; Fleur de Lis, 22 to 24-gauge, $4.50; 28-gauge American, $4.75; 30-gauge American, $5; bar, $2.50 base.

Pipe—Iron, black, per 100 feet, ¼-inch, $2.40; ⅜-inch, $2.55; ½-inch, $3-35; ¾-inch, $4; 1-inch, $5.75; 1¼-inch, $7 80; 1½-inch, $9.35, 2-inch, $12.50; galvanized—½-inch $4.35; ¾-inch, $5.20; 1-inch, $7.55; 1¼-inch, $10.25; 1½-inch, $12.25; 2-inch, $16.40. Lead, 7.60 per cent., full coil.

Pitch—Pine, $6.50 per barrel, in less than barrel lots, 4c. per lb.; roofing pitch, $1 per cwt.

Steel Plates, Rolled—3-16-in., $3.35 base; machinery, $3 base; share, $4.50 base; share crucible, $5.50; cast share steel, $7.50; toe caulk, $4.50 base tire steel, $3 base; cast tool steel, lb., 9 to 12½c.

Tool Steel—8½ to 15c. per pound.

The Canadian Engineer

A weekly paper for engineers and engineering-contractors

PRESENT METHODS OF TESTING MATERIALS

WITH SPECIAL REFERENCE TO THE WORK OF THE INTERNATIONAL TESTING ASSOCIATION—A PAPER READ BEFORE THE IRON AND STEEL INSTITUTE, BRUSSELS

By Professor H. HUBERT,

Department of Engineering, Liége University.

THE increasing importance of the use of metals in every description of construction, both of the stationary type, such as bridges and roofs, and of mobile type, such as the parts of machinery; the ever-increasing intensity of the stresses they are expected to withstand and of the energy they are required to transmit, have during recent years necessitated a more and more intimate knowledge of the properties of the materials employed and of the laws which determine the distribution of the stresses in the elements of the structure themselves.

Before dealing with the actual subject it might, perhaps, be advisable to make the following generalization: The most conclusive test, from the point of view of the strength of a structure, is obviously that which consists in subjecting the structure to the maximum it is required to undergo, or even to still greater stresses, so as to ensure complete security against all possible accidents. That is what is done, for example, in the case of ropes, in bridges, in boilers, and in pipes. Such tests are obviously of extreme interest from the point of view of the confirmation of the accuracy of the formulas employed in the calculations of dimensions, and of the hypotheses that it is often necessary to introduce into these calculations. They may also often be made to yield valuable data for the building of similar structures. An attempt has been made to introduce such tests into current practice. In this connection reference should be made to the methods and apparatus of Mr. Rabut, which have been applied to begin with in France, and to those of Mr. James Howard, which have been adopted by the Bureau of Standards in Washington, and were made the subject of a memoir presented to the Congress of the International Testing Association in New York in September, last year.

The first-named allows of the determination, with very close approximation to the truth, of the deformation l which a given length of piece L, forming part of a structure, undergoes, and of the stress being deducted from the formula $t = E \frac{l}{L}$, t being in this instance the tensile stress; or of plotting a diagram having as abscissæ the time, and as ordinates the deflections a metallic bridge undergoes under the influence of moving loads; or, finally, of measuring the angular deviation required in investigating the separate influences of overload and of wind pressure.

Howard's apparatus consists of telescopic callipers, furnished with points bevelled to an angle of 55 deg., which can fit into cavities tapering at an angle of 65 deg. in the pieces undergoing test. Mr. Howard has used this apparatus to investigate the deformation and stresses in the elements of bridges, flood-gates, "sky-scrapers," steam boilers, etc.

In the same connection may be mentioned the tests which have to be applied to the plates intended for the armouring of warships, or for the outsides of gun turrets in forts. These plates have to resist the violent impacts of projectiles. This property is one which can only be made manifest by tests carried out on plates placed in conditions identical with those they have to undergo in practice. In a paper, likewise presented to the New York Congress, Mr. Leonardo Fea shows, from numerous experiments carried out on chromium-nickel and on chromium-nickel-vanadium plates, that none of the tests to which metals are ordinarily submitted, such as tensile tests, compression tests, hardness tests, or fatigue tests, can afford an adequate conception of their behavior under fire. Fortunately such considerations do not obtain in every case, and it often happens that the determination of one or more of the elastic properties of a substance affords an engineer sufficient insight into its behavior in some other respect. For instance, tensile tests are carried out on cement intended for masonry buildings, where it will have to undergo compressive stresses. Experiment, as a matter of fact, has established a certain relationship between the two modes of resistance in cement, provided that the tests are carried out under special conditions, that is to say, on test-pieces always prepared in the same way and always stressed in the same manner. It is in this way, likewise, that a tendency has arisen to substitute hardness tests for tensile tests in iron and steel.

Great modern industries no longer confine themselves to the supply of their own national markets. The works of all civilized countries compete amongst themselves for the markets of the whole world. It has therefore become necessary that the conditions specified as to materials and the estimates of the cost of construction should be, as far as possible, uniform, and that indeed a single nomenclature should be everywhere adopted with the object of controlling the manufacture, of facilitating industrial relations, and of avoiding useless and often ruinous disputes. This standardization has been one of the leading objects which the founders of the International Association have had in view.

Before dwelling in greater detail on the work of the Association, it is necessary to enumerate the different kinds of test to which metals, and in particular iron and steel, are subjected, or to which it has been proposed to subject them. We can adopt the plan of the French Committee on methods of testing, and divide them into three groups:—

(1) *Chemical Tests.*—These are more especially carried out during the progress of manufacture, in order to ascertain the composition and degree of purity of the products. They are, however, also carried out by the purchaser as a check on the specifications controlling the sale.

(2) *Physical Tests.*—These consist of the examination of the exterior of the products and noting their fracture. The superficial examination may yield, to an expert, a general idea. The examination of the fracture, however, particularly when the surface can be projected, under strong illumination, on a screen and suitably enlarged, can yield more definite indications as to the qualities of steel and of cast iron, and as to the defects they may possess. Of late this method has been improved by polishing the surface of fractures and etching it with a dilute solution of acid, or of iodine, potassium iodide, alcoholic solution of hydrochloric acid, chloride of iron solution, or, finally and preferably, with a 10 per cent. ammoniacal copper solution which allows of a micrographic examination being made forthwith.

(3) *Mechanical Tests*, which were for long the only ones to which recourse was to be had in studying metals, still remain some of the most important and practical of tests. The rules or recommendations published by the International Association classify these tests, so far as metals are concerned, into resistance tests on subjection to various forms of stress (tensile, compressive, shearing, bending, and torsional) either applied gradually or suddenly, and workshop tests (bending double, bending single, hammering down, up-setting, punching, and drift tests). They differentiate besides the tests undertaken with a definite object in the case of (1) rolled and forged iron and steel rails, axles, tires, bridge sections, boiler material, shipbuilding material, wire, and wire ropes; (2) for cast iron; (3) for copper; and (4) for other metals and alloys.

The necessity of using, for tests of this nature, accurate and very costly machines, of taking rather large test-pieces from the materials to be tested, of subjecting these test-pieces to most careful and therefore somewhat expensive preliminary treatment, and of entrusting the tests themselves to an expert staff, renders the expense and the time required for such tests relatively large. Many inventors have sought to supersede them by more rapid and cheaper methods, even at the expense of sacrificing some degree of accuracy. Amongst such methods may be instanced the Frémont punch test, with automatic recorder, and the hardness test. The latter in particular has been for many years the object of numerous researches, and has given rise to lively discussions in the technical papers at Congresses of the International Association and at meetings of the National Testing Associations.

As Professor Martens points out in his important work on the testing of materials, "hardness" has been made the subject of many definitions amongst which it is not easy to make a satisfactory selection, and which have led to a number of methods for measuring it. He classifies these methods into two groups:—

(1) In the first group the hardness is ascertained by the penetration of a given body by another at a fixed point, the penetration being effected either by pressure or by impact.

(2) In the second group the penetrating body makes space for itself at the surface of the other body, which it scratches.

When penetration is effected by pressure, penetrants of various shapes are employed. In 1900 Brinell suggested the employment of a very hard spherical steel ball applied by the instrumentality of a hydraulic press, or by a weight, to the surface of the metal to be tested. It produces a depression of semi-spherical shape. If S be the area of this depression in square millimetres and P the pressure in kilogrammes applied to the ball, the ratio $\frac{P}{S}$, called the coefficient or hardness number, may be taken as a measure of the resistance of the metal to the ball, as it increases in proportion as the metal is harder. The ratio $\frac{P}{S}$ increases in any given metal when S is increased, or when the diameter of the ball is diminished. It also depends, within certain limits, on the time taken in making the test. To obtain comparable results it is necessary, therefore, to employ a ball of constant diameter, generally 10 millimetres, and a constant pressure, generally, in the case of iron and steel, 3,000 kilogrammes. On the other hand, from experiments made by Captain Grard, of Paris, it would appear that five minutes is sufficient for S to attain its maximum.

By carrying out numerous tensile tests on steel and comparing the results with those of the ball test, Brinell believed himself able to show that a definite relation exists between the breaking strain and the hardness number. If this be so, the ball hardness test would furnish an easy, rapid and cheap means of ascertaining the strength of a steel. It would also have the advantage of being capable of being applied to finished parts without injuring them, or to ascertaining the homogeneity of metal by making depressions at various situations. It would also furnish the manufacturer or user with an easy means of controlling the influences of thermal or of mechanical treatment, such, for example, as hardening or planishing. The interest which this process aroused may therefore be readily understood. Numerous investigators have sought to verify the relationship. In some instances it may be made to yield results very closely approximating to the truth by adopting the process of multiplying the hardness number by various coefficients in the case of hard or mild steels, and according as the impression is made in the direction of rolling or across the grain. Other observers, such as Mr. Breuil, have found that this method may result in very erroneous results, and the Brussels Congress would not consent to the substitution of the ball hardness test for the tensile test in specifications. The Congress, nevertheless, recognized the value of the process by recommending the determination of the hardness number in testing supplies. Since that time numerous other researches have been made and have given rise to another process of ascertaining the hardness by a method suggested by Martens and Heyn, which consists of taking the depth of the depression as indication of the hardness instead of its diameter.

At the Copenhagen Congress Mr. Ludwik, of Vienna, who had been deputed to report on hardness tests, con-

cluded, on the evidence of all the previously published data, that no simple relation existed between the elastic limit, the breaking strain, and the hardness, but that this did not exclude the possibility of deducing the elastic limit and the breaking strain from hardness tests by means of certain empirical coefficients. By determining the coefficient for each group of sufficiently similar materials, a fairly satisfactory approximation can be arrived at. Mr. Ludwik further notes that for metals that display contraction, the breaking strain does not yield an exact idea of the specific strength. The Copenhagen Congress came to no decision as to ball or cone hardness tests.

The last Congress, at New York, again had occasion to examine the question of hardness from the point of view of resistance to wear. From an important memoir by Mr. Saniter it appears that the relation between these two qualities is too uncertain for either to be deduced from the other. Nevertheless, Mr. Hibbard found that, of two steels of equal hardness, the one with the highest tensile strength had a higher resistance to wear, and that of two steels of equal tensile strength the hardest displayed the greater resistance to wear.

Side by side with ball and cone tests are other methods less frequently employed, but by no means devoid of interest. We may specially refer to the scleroscope method, described by Shore and Breuil, which consists in measuring the height to which a steel ball falling, through a given distance, on to the surface of the metal under test, rebounds, and Colonel Martel's method, which consists in measuring the volume of the impression produced by a pyramidal point falling from a certain height, and, finally, the sclerometers, which measure the depth of scratch produced by a steel point loaded with a predetermined weight.

Up to a certain point some degree of reliance may also be had on the method of photographing the sparks produced by steel when acted on by an emery wheel. Bermann, of Budapest, proposed at the New York Congress that this test should be adopted in the programme of the Association, pointing out that the results obtained show that the percentages of carbon silicon, and manganese in alloy steels can be accurately ascertained by comparing the sparks they produce with those produced by steels of normal composition.

Amongst circumstances exercising considerable influence on the strength of materials there is one which has been the object of numerous researches, and which has forced itself in the most urgent manner on the attention of designers ever since the speed of machines has risen considerably; it is the alteration and rapid succession of stresses which induces what is at present known as "fatigue" in metals. The earliest investigations of this subject were those of Wöhler (1857-1870). Later Spangenberg and Bauschinger (1870) devoted themselves to the question. Some earlier experiments are, however, attributed to Fairbairn.

Without recapitulating here the laws enunciated by Bauschinger, it may be said that both fatigue and hardness tests have as their object the ascertainment of the resistance of metals during use, that is to say, the stresses they can withstand indefinitely without breaking, applied in various ways and undergoing rapid variations and, in particular, changes in direction. Many methods have been thought out for applying such stresses by tension, by bending in one or more planes, and by reiterated shocks. The Brussels Congress did not deal with the matter. The Copenhagen Congress received a communication from Mr. Howard on tests carried out on two kinds of steel containing respectively 0.55 and 0.82 per cent. of carbon, and one by Messrs. Schule and Brunner on the endurance of copper wire under repeated tensile and bending tests. The subject was treated more fully at the New York Congress, where it gave rise to six important papers. That by Mr. Roos, of Stockholm, may be specially mentioned. He carried out experiments by subjecting test-pieces to static stress, by rotary coiling, and by repeated shocks of definite amount. He found that the limit of endurance increases in the same ratio as the limit of proportionality, of which it is on an average 0.65. Mr. Roos believed it possible to conclude from his own personal experience that 80 per cent. of the fractures in pieces that he had examined were due to fatigue and that much importance is to be attached to hardness tests. This conclusion was also arrived at in another paper contributed by Mr. Kommers on tests carried out on the Landgraf Turner machine. He attempted to deduce therefrom a "factor of quality" that might serve for commercial use. It may also be pointed out that the National Arms factory of Herstal, near Liége, which is one of the most important producers of automobiles, motor bicycles, and bicycles, tests the metals it employs by means of a machine which produces shocks of low intensity, rapidly repeated, on test-pieces of a given size.

This leads us, by a natural transition, to deal with a question which has been most strongly ventilated during the last few years, but upon which no agreement has as yet been reached. I refer to the determination of the resistance of metals to shocks of given intensity by means of a determination of their resilience.

The regulations published by the International Association as a result of the Brussels Congress contain a chapter relative to impact tests but dealing exclusively with tests made with a heavy weight (500 to 1,000 kilogrammes falling vertically), and the question of tests made on notched bars is not discussed. The Budapest Congress of 1901 had, however, already recommended this form of test. At the Brussels Congress Mr. Sauvage presented a detailed report on this subject, on behalf of the sub-committee of which he was a member. He gives a history of the publications relative to this type of test, and describes the different apparatus that had been suggested for carrying them out, particularly the Barba and Leblant spring tup, Frémont's spring pressure tup, the pendulum weight employed by Messrs. Bent, Russel, Charpy, and Unwin, and Guillery's rotating weight.

This test is made on a rectangular-sectioned test-piece notched on one side and resting on two supports. It is struck in the middle opposite to the notched side, so that fracture takes place with one blow. The work in kilogrammetres expended in delivering the shock divided by the cross section in square centimetres of the metal left at the bottom of the notch gives the resilience of the metal. The object is to reveal the brittleness of the metal. These tests are easily made, require but small test-pieces, and are inexpensive. Those who have investigated them claim in their favor that they are practical tests, as the parts of a structure during use often display reductions in section, and that they serve to bring out differences in metals that no other type of test reveals. It has, nevertheless, to be admitted that the results of these tests vary with the shape and dimensions of the test-pieces and of the notches, and it has not been proved that the brittleness such tests reveal is of the same nature as that which

operates during the actual use of such pieces. This was shown by Mr. Le Chatelier at the Budapest Congress of 1901. Mr. Sauvage's conclusion was likewise that they had failed to establish their claims. At the Brussels Congress Mr. Ast sought to establish a relation between impact tests on notched bars and tensile and bending tests. Comparison does not establish this relation. On the other hand, numerous facts observed by two officers of the Dutch artillery similarly led to a negative conclusion. The Brussels Congress also negatived the suggestion of inserting notched bar tests in specifications, while at the same time recognizing that the method was capable of yielding highly interesting results.

In a lengthy and important memoir which Mr. Breuil published in the "Revue de Mécanique" (1908-1909) he criticizes the different methods of testing notched bars and investigates the influence of different factors on the results, a subject he had previously dealt with in 1904 in his Carnegie Scholarship report to the Iron and Steel Institute. He concludes that this class of test exaggerates the differences between metals, without, however, conforming to any fixed law, and that it is better to make tensile tests on thin bars to ascertain brittleness. The notched bar test should only be employed to reveal the homogeneity of the metal.

The general meeting of the German Association on Methods of testing, however, held in Berlin on April 5, 1907, in adopting the conclusions of a report by a committee under the chairmanship of Mr. Martens, recommended impact tests on notched bars and recorded a preference for the Charpy swing weight. The delegates defended this resolution at the Copenhagen Congress in 1909, at which Mr. Charpy presented, on his own account, an important memoir on bending tests on notched bars. His conclusions were to the effect that these tests served to bring out the differences which failed to reveal themselves in tensile tests, and that it was not wise, therefore, to ignore them, although it was advisable to adopt a standard method in order to render comparable the results obtained by different investigators. The Congress discussed the question—which was, indeed, the subject of eight memoirs—at length, and adopted the following resolutions:—

The test bars should measure 30 x 30 x 160 millimetres, and should be notched to a depth of 15 millimetres. The bottom of the notch should have a curvature to a radius of 2 millimetres.

In the case of plates the bars may have the thickness of the plate itself and a width of 30 millimetres. The notch should be perpendicular to the rolled surfaces and have a depth of 15 millimetres, and a curvature at the bottom of 2 millimetres radius.

For pieces not admitting of the employment of bars of 30 x 30 millimetres, the bars should be 10 x 10 millimetres, and be notched to 5 millimetres with a curvature at the bottom of the notch to a radius of ⅔ millimetre.

The bars subjected to a bending test by receiving in the middle, and on the surface opposite to the notch, the impact of a falling weight rounded off to a radius of 2 millimetres. The bars rest on knife-edges 120 millimetres apart in the case of large test-pieces and 60 millimetres apart in the case of small test-pieces. As far as possible the temperature during testing should be between 15 degs. to 25 degs. C.

The bars should be fractured by a single blow by means of an apparatus which allows of the energy absorbed in breaking the bars being ascertained.

Finally, the Congress authorized a committee, under the chairmanship of Mr. Charpy, to study the relation existing on the one hand between the results given by notch bars tested under different conditions, and on the other, between the results of tests and the behavior displayed by metals under service conditions. The question was bound, therefore, to come up again at the New York Congress. It gave rise to nine memoirs. Mr. Charpy presented the report of the special committee, from which the following chief findings may be extracted:—

(1) The tests carried out by Messrs. Bartel, Ehrensberger, and Charpy appear to have proved that the resilience shown by small test-pieces is always lower than that shown by large test-pieces geometrically similar. The difference is greater in proportion as the resilience is greater.

(2) Tests by Messrs. Mercier and Mimey have proved that energy required to deform to a similar degree two similar test-pieces of similar metal is proportional to their volumes, and that if the height of fall, the masses of the falling weights, and the distances between supports satisfy the following ratios:—

$$\frac{\sqrt{H_1}}{\sqrt{H_2}} = \frac{M_1}{M_2} = \frac{D_1}{D_2}$$

the energy expended in producing deformation is proportional to the cube of their dimensions and not to the square.

Mr. Charpy recognizes that the employment of two types of test-pieces has not yielded the anticipated results, and that it would be advisable to increase the diameter of the notch in the case of the smaller test-pieces. It does not as yet appear possible to definitely impose any special type of testing appliance, but it is necessary to call attention to the importance of reducing losses of energy due to friction and vibration, and to the necessity of introducing a method of calibrating the apparatus.

The attention of the members of the Congress was pointedly directed to the declaration of Mr. Derihon, whose die-stamping works at Ans, near Liége, produce a large amount of automobile parts, exported to almost all parts of the world. Mr. Derihon used the Frémont weight and test-pieces, measuring 10 x 8 x 60 millimetres, with a notch of 1 millimetre in depth. From 80 to 100 tons of steel are used in his works, and 10,000 to 12,000 impact tests made per month. From 18 to 30 kilogrammetres of resilience is required according to the properties of the steels. To begin with, the specimens rejected amounted to 40 per cent. This result led to improvements in the method of treatment, until at the present time the number of failures has fallen to 3 per 1,000. On the conclusion of the discussion the special committee proposed to ratify the decisions of the Copenhagen Congress, and to collect together for the next Congress descriptions of the machines employed and of numerous comparative tests. The Congress confirmed this decision, and commissioned the committee to present at the next Congress definite suggestions as to the height of fall, the weight of the tup, the process of calibration, the form to be given to the supports of the test-piece, and a definition of the notch for small test-pieces.

According to Capt. Bernier, the Canadian Arctic explorer, who returned on Sept. 25th from Baffin's Land, there is no gold in that region, and previous statements attributed to him that gold had been discovered are pronounced incorrect.

THE BRITISH COLUMBIA ENGINEER.

ON October 13th, the Vancouver Branch of the Canadian Society of Civil Engineers held its first meeting for the winter session. It was largely attended, and was quite representative of both the Vancouver and Victoria Branches, as a large delegation from the latter was present to hear the address of Mr. G. R. G. Conway. Mr. Conway, who is Chief Engineer of the British Columbia Electric Railway Company, is Chairman of the Branch, and is an enthusiastic advocate for a more thorough organization of the engineering profession in Western Canada, and particularly in British Columbia.

In his address, the speaker referred to the benefits accruing to the Branch from its association with the Chamber of Mines, thus affording permanent headquarters, and the prediction was set forth of an Engineering Societies' building before a great lapse of time, this building to be the permanent home for the professional organizations of the province.

Reference was made to the many great and serious problems confronting the British Columbia engineer during recent years, occasioned by the enormous development of the national resources of the province, the building of railroads, the utilization of water powers, the construction of irrigation works, and the advancement of manufacturing industries, and a tribute was paid to the manner in which this engineering work was being directed and carried out. The Canadian Society of Civil Engineers came in for no small measure of credit, as, with few exceptions, the men who are responsible for these great engineering works, as well as their indispensable and important associates, are members of the Society.

Speaking of the members of the Society resident in British Columbia, Mr. Conway makes the following remarks:

"It is because of our real as well as our numerical strength, that the British Columbia members feel that a closer union between themselves is vital and necessary. It is true that we have important branches in Vancouver and Victoria, but we feel that our parent Society with its headquarters at Montreal is somewhat out of touch, both geographically and in spirit, with our Western ambitions. The local branch in Vancouver has been in existence now for about four years—but that is a long time as we measure our growth here. The Victoria Branch is even more youthful. We feel that we must rouse ourselves into vigorous activity so that our honored and venerable Parent will appreciate that her lusty western branches have arrived at years of discretion and are able to judge what is good for their own progress, and how that progress can assist the national Society. In anything we suggest, we wish to be quite emphatic that nothing shall be done that will divorce us from, or alienate the sympathies of, the parent Society; but that the wish of all of us is to broaden and increase the influence of the Canadian Society of Civil Engineers so as to make it a truly representative national Society, weilding a more powerful and beneficient influence over the whole Dominion than it does at present. We do not want it to become—as Western members are sometimes inclined to think it may—a purely local Society for members in the neighborhood of Montreal and Ottawa, living under the influence and fostering care of McGill University, but rather a Society that shall adequately represent the engineering activities in all the great provinces.

"At the present time we have about 240 members in British Columbia, who gain practically nothing from the parent Society, and who feel that any benefit that comes to them from membership is entirely dependent upon local efforts. We have been discussing for some time past, the formation of a British Columbia section of the members, so that our influence in the province will be more fully recognized, and to obtain for ourselves a greater share in the government of the Society so far as our Provincial interests are affected, than is possible under present conditions. We have taken these matters up with the Council of the Society, and are now proposing to forward for consideration at the Annual Meeting in January, at Montreal, a definite proposal which I hope will be cordially endorsed by all the members in British Columbia. Briefly, the proposal is that we shall form a Provincial Division of the Society and still retain the local branches, who will co-operate in all matters that are vitally important to the members in British Columbia. This co-operation, we believe, is of great importance when approaching the Provincial Government on public matters, so that in any petitions it will be felt that we are a united body of trained specialists, who in an advisory capacity might be of great assistance to the Government in the many problems that arise where engineering counsel is necessary. Furthermore, we wish it to be recognized that in the ranks of the Canadian Society of Civil Engineers the best engineering talent in the Dominion of Canada can be found. It is our ambition to place the Canadian Society upon the same influential plane as that occupied by the Institution of Civil Engineers of Great Britain and the American Society of Civil Engineers, whose recommendations to their Governments are not only welcomed but eagerly sought."

Another matter upon which Mr. Conway dwelt to some extent, emphasizing the interest it held for members of the engineering profession in British Columbia, was the provincial university, and its proposed facilities for the training of men in the engineering. He urged the establishment, in addition to the essential departments of civil, electrical, mechanical and mining engineering, of course in economic geology and mineralogy, and a department for the special study of irrigation and the conservation of water, stating the future of the central portion of British Columbia was dependent upon a scientific understanding of the proper storage and proper disposal of water for irrigation. Courses in forestry and in naval architecture were also urged.

In speaking of the engineering works of the province reference was made to the many problems involved in the construction at the present time of 3,000 miles of railway at the cost of $175,000,000; of the magnitude of municipal work; of the development of the vast water power resources, which are conservatively placed at 3,000,000 h.p., and of the difficulties to be surmounted in mining engineering and the lumbering industry. Considering what remains to be accomplished, and considering also the field for harbor engineering, there are unlimited opportunities for the engineer on the Pacific Coast.

Industries are being crippled by lack of proper dock accommodations in Vancouver, and it is difficult to predict how prepared Vancouver will be in 1915 when

the Panama Canal begins to make its influence felt. It was emphasized that more attention should be directed to accommodation for water traffic.

"In Burrard Inlet we have, with the exception of San Francisco, the finest harbor on the Pacific Coast, one that needs no great expenditure to protect it from storms, as many famous harbors have done, but one where the requirements are chiefly wharves and docks that will be absolutely necessary, if we are to maintain a great trade with Europe and with the awakening Orient. The engineer can transform Burrard Inlet into one of the finest harbors in the world, and although some activity has already been shown by our parliamentary representatives in rousing interest in these enterprises, we are delaying too long in starting the project."

Following a discussion of the status and needs of the engineer in British Columbia and of the part which the Vancouver Branch of the Canadian Society of Civil Engineers, was destined to play a resolution was put, and unanimously adopted, to submit to the parent Society in Montreal, the following proposal.

Proposed Change in the By-Laws of the Canadian Society of Civil Engineers.

A new By-law to be numbered 56, and to read as follows:—

A Provincial Division of the Society may be established under the authority of the Council at the request of the majority of the corporate members residing in the Province.

All members residing within such Province shall be members of the Provincial Division so formed.

The officers of a Provincial Division shall be a Chairman, a Secretary-Treasurer, or a Secretary and a Treasurer, and a Committee of four or more members. The Committee shall be elected by a letter ballot of the corporate members residing in the Province. The Chairman and the Secretary-Treasurer, or the Secretary and the Treasurer, shall be elected by the Committee.

The Constitution and By-laws of all Provincial Divisions shall be subject to the approval of the Council of the Society. The Secretary of the Provincial Division shall transmit to the Council, copies of all minutes of meetings, and reports of all proceedings of the Division. The Secretary and the Treasurer shall present a yearly report to the Annual Meeting of the Society.

The Parent Society shall, in addition to the rebate to the branches, grant a further rebate to the Provincial Division of One ($1.00) Dollar per head for every corporate member in the Province, other than those connected with the local branches.

The proposal was forwarded to the Secretary of the Society, formally signed by the most prominent and representative engineers in the West, some of whom are among the oldest members of the Society. The names of those signing were: H. J. Cambie, Thos. H. Tracey, T. H. White, A. E. Hill, F. L. Fellowes, F. C. Gamble, G. R. G. Conway, J. H. Kennedy, R. F. Leslie, G. H. Webster, H. M. Burwell, J. F. Garden, H. B. Smith, H. Carry, and J. R. Grant.

Great interest has been taken in the proposal of the British Columbia members, their object being to strengthen the hands of the Provincial members, and in so doing it is their belief that the parent Society's influence will be strengthened.

INDUSTRIAL DEVELOPMENT IN FORT WILLIAM.

The tremendous growth of Fort William's transhipping trade within the past few years has given great impetus to the development of the city, but Fort William was not contented to remain merely a transhipping point, her citizens realizing the importance of what nature had already done for the city in the way of harbor facilities, etc., and, seeing that the geographical situation destined the city for a strategical manufacturing point of importance, they have through various channels aided and encouraged manufacturing industries to establish at the head of the lakes, and as a result Fort William is to-day rated as one of the important manufacturing centres of the Dominion.

During 1912 Fort William secured some ten manufacturing industries which are erecting plants valued at nearly $4,000,000 and giving employment to close on to 3,000 men.

Among the leading manufacturing industries of the city it is important to note the following:—

The Canadian Car and Foundry Company, Limited, whose plant is now under construction and will cost in the neighborhood of $2,000,000 and give employment to 1,600 men.

The Canada Iron Corporation, Limited, with a million-dollar plant employing nearly 500 men.

The Canadian Steel Foundries plant, to be erected within the next twelve months at a cost of $250,000 and to employ 250 men.

The National Tube Company, Limited, with a plant and equipment valued at $400,000 and practically now ready to begin operations with a staff of 150 employees.

One of nature's valuable gifts to Fort William is the water power available. Within a radius of 50 miles of the city there is water power to the extent of probably 1,000,000 horsepower available. Some 35,000 horsepower has been developed at Kakabeka Falls, on the Kaministiquia River, 17 miles above Fort William. This power has been developed by the Kaministiquia Power Company.

Fort William's harbor and rail facilities are well known. In connection with western Canada's grain crop, it is of some interest to note that Fort William has 23 elevators, with a combined capacity of close on to 30,000,000 bushels. The largest elevator at present in Fort William is the Grand Trunk Pacific, which has a capacity of some 6,500,000 bushels. Additional annexes are being added from year to year that will ultimately bring the total capacity of this elevator to 40,000,000 bushels. This city has been chosen as home of the board of grain commissioners and is to be the headquarters of the grain sample markets.

Iron and other mineral deposits exist in the immediate vicinity. Quite recently considerable development work has been undertaken and samples of iron ore, assaying from 43 to 65 per cent., have been procured.

Lumbering forms a very important industry at and near Fort William and gives steady employment to a great many men and within a fifty mile radius of the city is much arable land.

ELECTRIFICATION OF THE LÖTSCHBERG RAILWAY.

The recent opening of the Lötschberg Railway affords a rapid connection between Italy and the western countries of Europe. The enterprise included a tunnel nine and one-fourth miles in length through the Alps. Reference was made to the construction of this tunnel, which is the third longest on the continent, in July 24th issue of *The Canadian Engineer*, where it was also stated that electric traction would be used.

The locomotives which have been put into service upon this line are claimed to be not only the largest locomotives so far constructed, but, generally speaking, the most powerful locomotives in the world. They are described in detail in a recent issue of *The Electrical Review*, (Eng.,) from which the accompanying illustrations and much of the data are reproduced. Experimental operation on the Spiez-Frutigen section showed the suitability of the single-phase system for the operation of trunk railways, and electrical operation was definitely introduced in 1910 on this portion of the Lötschberg Railway, the trolley line pressure being 15,000 volts, and the periodicity, 15 cycles. The Oerlikon Company supplied the first locomotive with an output of 2,000 h.p. during an hour's working at a speed 42 km, (20.1 mi.) per hour, and this was equipped with two motors each of 1,000 h.p. The satisfactory results obtained with this locomotive during the last two years induced the railway company to entrust the same company with the design of 13 locomotives equipped with motors of even greater power, for the through service on the Thun-Spiez-Brigue Line.

These new locomotives, are designed to develop 2,500 h.p. during 1½ hours' uninterrupted service, at a speed of 50 km. (31.07 mi.) per hour, and have five coupled axles and two free axles. The pull on the drawbar at normal speed is 10,000 kg. (11.02 tons), which suffices for hauling a train of 310 tons over a gradient of 27 per cent., or a train of 530 tons over a gradient of 17 per cent., at a speed of 50 km. (31.07 mi.) per hour, the pull at the wheel circumference being 13,500 kg. (14.88 tons). The maximum speed has been fixed at 75 km. (40.6 mi.) per hour. The locomotives are able in starting to develop a pull 30 per cent. above the normal figure, that is, of about 18,000 kg. (19.82 tons).

As regards the mechanical part, the longitudinal frame carries the body of the locomotive, which comprises three compartments, viz., the engine room and the drivers' cabins, which are separated from the former by partition walls and doors. In order to ensure the greatest possible freedom on curves, the central (driving) axle has been given a side-play of 25 mm. (0.984 in.), the two inner coupled axles are located rigidly in the frame, and each of the two outer ones, having a side-play of 40 mm. (1.5748 in.) is connected with the corresponding fee axle, thus forming what is called a Krauss-Winterthur bogie. In the case of the free axle an even greater side-play has been provided, thus allowing curves of only 120 m. (393.7 ft.) radius to be negotiated in spite of the considerable length of the locomotive. The central axle has spiral springs and the coupled and free axles plate springs.

The hand brake in each driver's cab acts on the free and coupled axles situated near by and on a brake block on the driving axle. In view of the considerable gradients on the line, the locomotives have been equipped with the Westinghouse automatic brake and a regulating brake. From the driver's platform are also controlled the whistle and sanding device which, like the collector bow, and part of the safety devices, door-locks and ladders are operated by compressed air.

All the electrical equipment has been duplicated, thus allowing the locomotive to be operated with half of its equipment, that is, with one transformer and one motor and accessories. Provision has also been made for the two halves of the equipment to work either in series or in parallel, the two motors being fed from either transformer, so that the locomotive will, for instance, develop its full tractive effort with a single transformer and controller, and both motors arranged in series, and be able permanently to keep up its full speed with one motor.

The current goes from the 15,000-volt line through the two bow collectors over two choking coils, to the two halves of the electrical equipment, viz., through two high-tension oil switches to the two transformers and two earthing slip-rings fixed on the rigid axles, to the rails.

The high-tension oil switches allow the whole of the machinery to be switched off. For the sake of safety there have been fitted on both sides of the oil switches, earthing switches which are closed while the doors of the high-tension compartments are kept open.

Fig. 1.—Locomotive and Train, Lotschberg Railway.

The transformers are air-cooled, the low-tension coils having 12 tappings for controlling the speed. A special fan fitted to each transformer ensures thorough cooling.

In operating the controller, perfectly smooth starting with a practically constant pull is obtained, on account of the low pressure difference (45 volts) between the various steps, the power factor being about .95 with all loads at normal speed. These favorable starting conditions are, or course, of the utmost importance to the power station supplying the line, especially during the simultaneous starting and shunting of several trains.

Fitted on the transformer, and combined with it, is the controller, the contacts of which are connected directly with the low-tension windings of the transformer. All parts of the switch subject to wear are readily exchangeable. Current interruption proper takes place on a secondary drum with magnetic spark damping, whereas any alterations in the connections of the main-switch drum occur under no-voltage conditions. The switching is effected mechanically by a small auxiliary motor fed with direct current, which, through the

intermediary of a wormgear, actuates a pawl mechanism. The pawls are controlled by electro-magnets energized from the driver's platforms. According as one or other of the pawls is actuated, the switch drum will rotate in either direction, thus making or undoing the connection.

These controller switches, as well as the low-tension oil switches, are designed for a maximum current of 3,600 amperes.

The two motors, each designed to give 1,250 h.p. on the rails during 1½ hours' uninterrupted operation, are of the Oerlikon compensated series type, rigidly fitted into resilient frames. They drive through tooth-wheeled gearing with a ratio of 1:2:23, fitted into the motor housing, on to the motor shaft, which is a loose axle connected by the driving gear to the coupled driving axle. The cranks of the two main shafts of the motors are connected by a triangular rigging to the cranks of the driving axles. This arrangement avoids practically any non-resilient part, the spring action in the triangular rigging with the central driving axle being accommodated by a vertical rubbing plate.

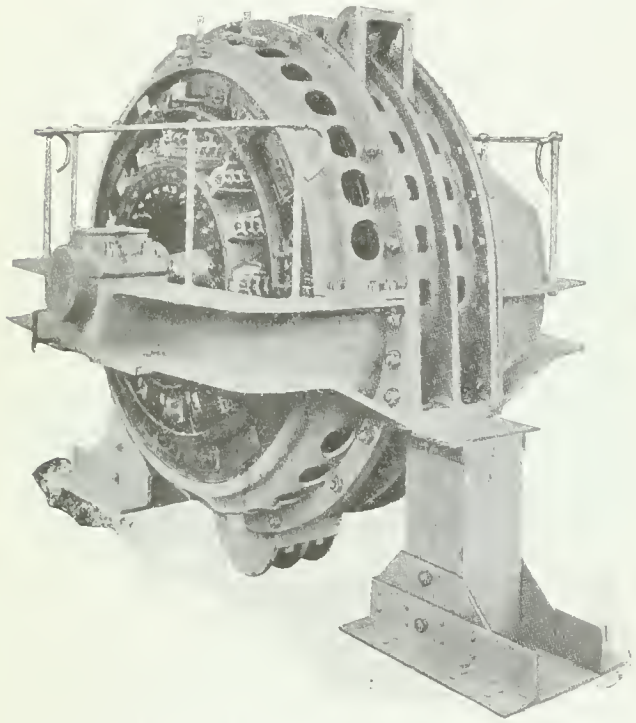

Fig. 2.—Oerlikon Motor for 2,500-H.P. Lotschberg Locomotive.

The motors are of the 16-pole open type, the air being allowed free access everywhere. They are fed at a maximum pressure of about 430 volts, and are designed to absorb about 3,000 amperes, at their maximum output. A ceiling fan fitted above the motors ventilates the whole of the motor compartment. This motor system which has also been used in connection with the 2,000 h.p. experimental locomotives previously referred to, shows most favorable starting conditions, thus greatly facilitating the shunting of the locomotives. In starting at full power, the locomotive only requires about a third of the normal overhead line current. Another advantage of this system is its practical independence of the number of cycles and of any speed limitation by synchronous number of turns. The normal speed of the locomotive is reached with four times the synchronous number of turns of the motors. The power and speed of the motor are also independent within wide limits of the overhead line voltage, any considerable drop in the line voltage being compensated by suitable transformer winding, while the motor with only one-third of its normal voltage, is able permanently to develop its full power. This provides for great overload capacity of the motors at normal pressure.

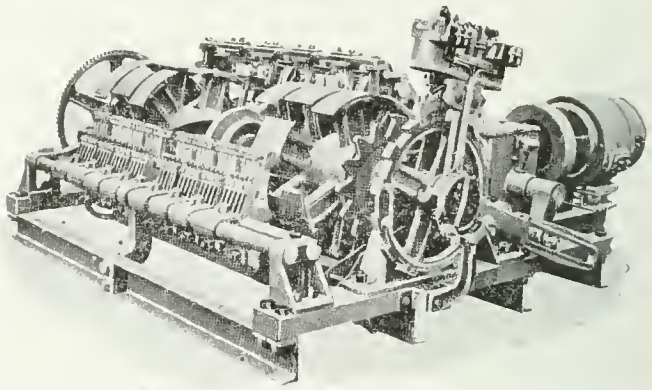

Fig. 4.—Motor-Operated Controller, 2,500 H.P., Lötschberg Locomotive.

Fitted direct on to each motor and electrically connected with it, is the controller for reversing the direction of travelling. This alters the current direction in the exciter coil, and is controlled through electro-magnets from the driver's cabin. In case of emergency these controllers, as well as the remaining apparatus, can be operated by hand.

Current for the auxiliary motors and for heating, can be derived from either transformer by means of switch fuses, the heating current being switched in from the drivers' platforms.

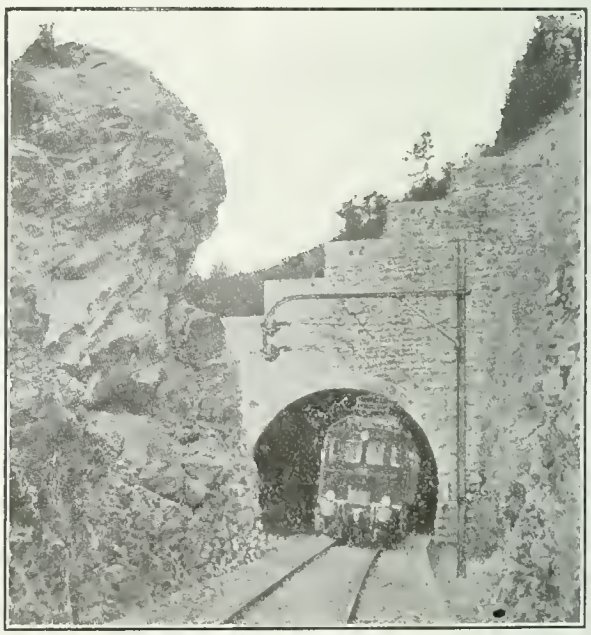

Fig. 3.—Entrance to the Lotschberg Tunnel.

A converter set supplies continuous current to the remote control and the lighting, in parallel with four ordinary train lighting batteries, and is also controlled from the driver's cabin. All the requisite switches and instruments are installed in the drivers' cabins.

The two high-tension compartments in the motor room of the locomotive are closed by lattice-work doors, which are so locked that the high-tension circuit in front of and behind the high-tension oil switch has to be earthed before opening them. The key used in undoing this lock is arranged on a tap connected to the bow air conduit and cannot be removed unless the tap is opened, thus causing any air in the bow conduit to be discharged. This key cannot be withdrawn from the lock before closing all the doors, thus preventing the high-tension compartment from being opened while "alive." Means have also been provided for the oil switches to be operated by hand only while under no-voltage. In order to keep the operator informed of the actual position of the apparatus in the case of hand operation, signal lamps have been provided for the controller and direction of travelling. The folding ladders for climbing to the roof are mechanically connected with alarm whistles, which are actuated in the event of there being any compressed air left in the bow air conduit on lowering a ladder.

The following is a summary of the principal data:—

General data: Single-phase alternating current system, 15,000 volts and 15 cycles per second.

Gauge, 48 ft. 8 in.; maximum gradient, 27 per mile.

The principal data of the locomotives themselves are as follows: Maximum length between buffers, 52.5 feet; total wheelbase, 36.86 feet; rigid wheelbase, 14.76 feet; diameter of driving wheels, 4.43 feet; diameter of free wheels, 2.79 feet; maximum axle weight, 16.6 tons; friction weight, 78.2 tons; total weight, 104 tons; output during 1.5 hours, 2,500 h.p.; pull on wheel during 1.5 hours, 1,488 tons; speed for 1.5 hours, 31.07 miles per hour.

COPPER-ZINC ALLOYS.

Considerable discussion has taken place lately regarding the several advantages for engineering work of the copper-tin alloys, or true bronzes, and the copper-zinc alloys, which are usually generically termed brasses. It will be remembered that quite recently a firm of continental engineers introduced a new alloy of the latter type, which is expected to prove of special value. It would not appear possible yet to give any details as to the behaviour and durability of this alloy in actual service, owing to the fact that it has only recently been obtainable. An interesting paper was recently read by Dr. C. H. Desch and Mr. S. Whyte, both of Glasgow University, on the "Corrosion of Copper-Zinc Alloys," from which much valuable information can be obtained, and which throws considerable light on the subject. It appears that the results of certain tests carried out emphasized the importance of distinguishing between material which was actually dissolved and that which merely lay in strata in the mass. It was found that the effect of quenching from above, the transformation temperature increased the tendency to corrode. It was demonstrated that there was no evidence that the alloy containing tin had any less tendency initially to corrode than any of the high-grade brasses. It was proved, however, that the presence of iron, as had long been suspected to be the case, did increase the tendency of the alloy to corrode.

MICA DEPOSITS IN CANADA.

Concerning the importance of Canada as a mica-producing country, very interesting information is given in a report issued by the Department of Mines in a pamphlet by Mr. J. McLeish, called *Economic Minerals and Mining Industries*. The following paragraphs have been taken from the same:—

"With the exception, perhaps, of Ceylon, Canada is the only country, as far as is yet known, in which the variety phlogopite—or 'amber mica,' as it is termed in the trade—is known to occur in economic quantities. The mica of commerce is of two kinds—muscovite, or 'white mica,' and phlogopite, or 'amber mica.' The former is obtained from both India and the United States, while the latter is secured almost wholly from Canada. Of the two varieties, phlogopite commands rather the higher price, being softer and more flexible and altogether more suitable for use as an insulator—this being the principal use to which mica is put at the present day.

"The amber mica deposits of Canada are comprised within an area of approximately 1,200 square miles in the province of Quebec, and 900 square miles in the province of Ontario. The two districts are separated geographically by the Ottawa River, and geologically by a belt of sedimentary rocks about 40 miles wide. The city of Ottawa lies between the two productive areas and is the seat of the mica industry—all the important works engaged in trimming and in otherwise preparing the mineral for the markets being located in that place.

"Deposits of white mica, also, occur in Canada, and occurrences of this variety (some few of which have been worked at various times), are known from Labrador in the east to the Rocky Mountains in the west, while several Arctic expeditions have returned with good specimens from the far north.

"Though the average dimensions of mica sheets do not much exceed 3 x 5 inches, plates of enormous size are sometimes obtained. Crystals have been found which measured over 4 feet across and weighed nearly two tons.

"About 300 mines have been worked for mica at various times in Canada, but at the present day no more than 25 are in active operation. Among the large operators may be named:—The General Electric Company of Schenectady, N.Y.; Webster and Company, Ottawa; Blackburn Brothers, Ottawa; Wallingford and Company, Ottawa; O'Brien and Fowler, Ottawa; Kent Brothers, Kingston."

NATIONAL MUNICIPAL LEAGUE.

The National Municipal League convenes in Toronto on November 12th, 13th, 14th and 15th.

USES OF COAL TAR.

Tar, a bye-product from the coking of coal, is used largely for two purposes, namely, distillation for production of creosote and light oils and pitch, and for use in road-making, giving a smooth and dustless surface to macadamized pavement. Both of these uses of tar have increased very greatly in the last few years, and the tendency for still further increase indicates a very large proportion of the future production will be similarly used. Tar is further being used successfully in open-hearth furnaces, replacing producer gas; also in heavy oil engines, providing it does not contain too much free carbon.

SANITARY SURVEY OF RIVERS.

By R. O. Wynne-Roberts,
Consulting Engineer, Regina.

(Continued from last week's issue.)

THE authors then state that in Sept., 1911, the Des Plaines at Lockport was much more offensive than the canal, its organic contents being evidently in far more advanced stage of decomposition. Stones and pebbles were completely covered over with septic growth of sphœrotilus and algæ, mainly blue-green species. The water had a grayish look and a filthy smell, evidently much too foul for even the most indifferent species of fish. The content of dissolved oxygen was, however, higher in the Des Plaines than in the canal, being 44 per cent. of saturation.

At Dresden Heights, the dissolved oxygen content averaged 13.1 per cent. at 68 deg. Fahr., but in the Kankakee River, close by, it averaged 126.8 per cent. at a temperature of 71.6 deg. Fahr. In other words, the Kankakee River water was supersaturated with oxygen. Kankakee River water held in solution 2.1 parts per million of carbon dioxide as compared with 12.8 parts in the Des Plaines.

Slime worms (*Tuberficidæ*) were rare in the soft, black sludge in the Des Plaines.

Decomposition of its sewage material had not reached its climax, which came at Morris and Marseilles, at low water in the hottest weather.

"Conditions in the Kankakee at its mouth are particularly interesting and important, since they give us a close approximation to those of the natural water of the Illinois River, derived, as they are, from a territory similar in character to the valley of the Illinois below, and contaminated but slightly, if at all at this place, by way of contributions from comparatively small towns at some distance above."

The average of nine determinations of oxygen in this river was 103.8 per cent. of saturation. In the forenoon it averaged 101.7 per cent. and in the afternoon 121.2 per cent. The afternoon increase was doubtless due to the liberation of oxygen by submerged plants under the influence of sunlight. This phenomena is corroborated by Messrs. Clark and Adams, who found green growths (Chlorophyll) to give off free oxygen when growing in light, and that water containing chlorophyll-bearing organisms take a greater part in overcoming sewage pollution in surface waters than is at present generally realized.

Messrs. Forbes and Richardson found no blue-green algæ, no fixed form of protozoa, no oligochæte worms, no sewage fungus in the Kankakee River water.

At Morris, the Des Plaines River water flowed more or less along the north bank and the Kankakee River water along the south, and it was plain by the dissolved oxygen tests that the waters had not mixed.

An extensive deposit of sludge, 5 to 6 feet deep in places, was formed at the lower end on an island. Some gases from this sludge were collected and analyzed, with the following results: Carbon dioxide, 18.96 per cent.; oxygen, 0.03 per cent.; carbon monoxide, 0.56 per cent.; methane, 79.25 per cent.; nitrogen, 1.19 per cent. The abundance of carbon dioxide and the almost complete absence of oxygen are, of course, to be understood as due to organic decomposition in the presence of oxygen, and the methane is evidence of the continuance of the decomposition after the available oxygen was exhausted.

"**Sludge Worms.**—It is clear that neither plants nor animals requiring oxygen could live in these sediments at the bottom of the stream. The abundance of Tuberficidæ imbedded in this is explained by the extraordinary respiratory capacity of these worms, and by the fact that their respiratory structures are situated at the anal end of the body, which projects above the bottom and is kept continually waving back and forth. Their circulatory system likewise specially adapts them to live in water with a minimum of oxygen, the blood containing sufficient hemoglobin in solution to give it a red color, and being kept in active circulation through a closed system of blood-vessels."

"**Marseilles Dam.**—The situation of quarter of a mile above the dam may best be described by a comparison with that at Morris, these points being but seventeen miles apart, with no important tributary of the river or other modifying factor coming in to interfere with the spontaneous development of conditions within the stream itself. Another important and interesting comparison is that of chemical and biological data from above and below this dam, since this comparison will show us what and how great are the effects of the fall upon the polluted water."

"The analyses for August, 1911, show oxygen ratios of 20.4 per cent. at Morris on the 11th, and 11 per cent. at Marseilles on the 12th, 16.35 per cent. at Morris on 22nd and 23rd, and 7.4 per cent. at Marseilles on 24th and 25th. The carbon dioxide ratios, on the other hand, were much larger at Marseilles than at Morris on these dates. Active decomposition of organic matter was thus clearly evident in this midsummer weather, at low stage of water then prevailing. With higher water and cooler weather the difference between Morris and Marseilles were greatly diminished, the percentage of saturation, February 16th to 20th, standing at 48.76 for Morris and at 43.70 for Marseilles. In the fall of the following year these ratios were, in fact, reversed, the Marseilles determinations being 5 per cent. higher than at Morris, Sept. 27th and 9 per cent. higher, Nov. 14th."

"**Below the Dam.**—Turning now to the situation below the dam at Marseilles, in July and August, 1911, the ratios of dissolved oxygen three-fourths of a mile below were more than three times as great as those above; that under winter conditions in February and March they were 13 and 14 per cent. greater; and that in August and September, 1912, with cooler weather and higher water levels than in the previous year, they varied from one and a half to two times as great. The necessity of taking samples for analysis at some distance below the dam was shown by the fact that the oxygen content of the water, September, 1911, an eighth of a mile below was more than ten times that above—a discrepancy to be accounted for only on the supposition that the air mechanically caught in the water at the fall had not yet had time to escape."

At Starved Rock, which is 95 miles from the mouth of Chicago River, the odor of the water in August, 1911, was still disagreeable, and sewage fungus still found floating in the current.

At Chillicothe, 145 miles down stream, in July and August, 1911, the water had a distinct greenish cast, without odor and mud taken from the bottom had a good, fresh smell. In March, 1913, however, the sludge from a deposit 2 feet deep had a distinct sewage odor. The cooler temperature of the water—41 deg. Fahr.—delayed decomposition. The river was, however, still far below a normal unpolluted stream in oxygen ratios, and contained much more carbon dioxide. The average of dis-

solved oxygen tests in August, 1911, gave 3.70 parts per million, but in Nov., 1911, it was 10.15 parts per million, equal to 84 per cent. of saturation.

"**Summary by Stations.**—The Sanitary Canal at Lockport.—Although the water of the canal at Lockport was comparatively clear, with an inoffensive odor, even in August and September, 1911, it was not only heavily loaded with putrescible materials from the Chicago sewage, mainly as yet undecomposed, but it was lower in oxygen content at most times than the river water either of the Des Plaines or the Illinois at any point where our tests and collections were made. In the winter, however, the amount of oxygen in solution approximated the ratios of an unpolluted stream, being actually higher in February, 1912, than at any point between Lockport and Peoria. This is to be understood, of course, as due to the gradual start and slow decomposition of the self-purification process in cold weather."

"**The Des Plaines River at Dresden Heights.**—The Des Plaines at its mouth was heavily loaded with putrescible sewage materials so far advanced in decomposition that oxygen ratios were always very low. They differed, however, according to seasons, in comparison with those of the next lower stations, being higher than these in the hottest weather and lower at lower temperatures. In July, 1911, for example, when the water of the Des Plaines contained 1.21 parts per million, that of the Illinois stood at 1.07 at Morris, and at 0.83 above the Marseilles dam. In November, 1912, on the other hand, the corresponding figures were 4.90 for the Des Plaines, 6.80 for the Illinois at Morris, and 7.90 at the Marseilles dam. This seasonal difference is again to be accounted for by the different effect of low and high temperatures upon the beginning and rapidity of decomposition process in a polluted stream."

"**Morris to Marseilles.**—In the seventeen-mile section of the Illinois from Morris to the upper dam the river reaches its lowest point of pollutional distress, becoming, when very hot weather coincides with a low stage of water, a thoroughly sick stream. Its oxygen is nearly gone; its carbon dioxide rises to the maximum; its sediments become substantially like the sludge of a septic tank; its surface bubbles with the gases of decomposition escaping from sludge banks on its bottom; its odor is offensive; and its color is gray with suspended specks and larger clusters of sewage organisms carried down from the stony floor of the polluted Des Plaines, or swept from their attachments along the banks of the Illinois. On its surface are also floating masses of decaying debris borne up by the gases developing within them, and covered and fringed with the sewage fungus (*Spheorotilus natans*) and the bell animalcule (*Carchesium lachmanni*), usually associated in these waters. The vegetation and drift at the edge of the stream are also everywhere slimy with these foul-water plants and minute filth-loving animals."

The authors, in bringing their report to a close, express a few results of their investigations, and the following extracts are, perhaps, sufficient to indicate what they are:—

General Summary of Chemical Features.—"The lowest ratios of dissolved oxygen in the upper Illinois were found in July and August, 1911. When determinations at the mouth of the Kankakee varied but little from 10 parts per million, those from the mid-stream at Morris, nine miles below, ranged from 0.24 to 1.78; at Marseilles, above the dam, 2.18; and at Starved Rock, 3.18. At Chillicothe the ratios varied on different days from 2.10 to 4.21 parts per million, with an average of 3.47. Single determinations at the lowest of our river stations yielded as little as 19.5 per cent. of saturation, and the average of all our midsummer determinations here for 1911 was but 40.8. As the Kankakee River average at this time was 112.2, it appears that during the upper ninety-three miles of its course the Illinois did not regain much more than a third of the oxygen lost to the Chicago sewage."

"A trip was made for chemical determinations, February 1st to 8th, 1912, from Lockport to Chillicothe, and another, March 18th to 28th, from Lockport to the mouth of the Illinois at Grafton. The water temperatures averaged 34 deg. Fahr. on the first trip and 35 deg. Fahr. on the second trip, the upper river being quite frozen over much of the time.

"The oxygen determinations of these trips differ widely from those of the preceding midsummer in the much higher ratios found in the winter, and in the fact that the lowest point for oxygen was very much farther down the stream. In all our midsummer trips this lowest point was reached at the Marseilles dam, but in February there was less oxygen at Chillicothe than at Marseilles, and in March, when the whole of the river was traversed, the oxygen ratios declined down stream from Marseilles to Havana, rising then gradually to the mouth of the Illinois. At Morris the ratio of oxygen was more than six times as great in February as in midsummer; above the dam at Marseilles it was more than eight times as great; below the dam more than three times; and at Chillicothe it was 30 per cent. greater. The March ratios from Morris down were much higher still, reaching a maximum of 10 parts per million below the Marseilles dam, falling thence rapidly to Peoria (0.8), dropping a trifle only at Peoria below the outlets of the sewer system (6.5), declining slightly to Havana (0.2), and rising steadily to the mouth of the Illinois (9.4), the water of the Mississippi standing at the same time at 10.5. In the entire distance from Lockport to Grafton the percentage of oxygen saturation on this March trip did not fall below 44 (Peru), nor rise above 75 (south shore, Morris)."

The Effect of a Dam on Dissolved Gases.—"The fall over the Marseilles dam in the hot weather and low water period of July and August, 1911, had the effect to increase the dissolved oxygen more than 4½ times, raising it from an average of 0.64 parts per million to 2.94 parts. On the other hand, with the cold weather, high oxygen ratios, and higher water levels of February and March, 1912, and the consequent reduced fall of a large volume of water at Marseilles, the oxygen increase was only 18 per cent.—from 7.35 parts per million above the dam to 8.65 parts below; and in August and September, 1912, the weather being still cooler, and the water lower than in the midsummer of the previous year, the increase was only 77 per cent.—from 2.05 parts per million above the dam to 3.62 parts below. It should be noted, however, that this beneficial effect is greatest when it is most needed—when the pollution is most concentrated and decomposition processes are most active. In the absence of a dam at this point the recovery of oxygen used up in decomposition would be greatly retarded in midsummer, and heavily polluted water would be carried much farther down the stream."

Seasonal Phases of Chemical Condition.—"The midsummer and the winter phases represent, of course, the extremes between which the fall and spring conditions come as intermediate or transition stages. The midsummer phase, with its high temperatures and low stage of water, is characterized by a concentrated pollution and an early and rapid decomposition and deoxygenating

process, with lowest oxygen readings at Morris and above the dam at Marseilles, followed by a sudden increase of oxygen below the dam and a gradual rise in ratios thence down the stream to its mouth. The winter phase contrasts with this by a delay of decomposition such that the oxygen ratio is highest at Marseilles, declines slowly to the middle of the river's course (about Havana), and then rises gradually to its mouth. In the autumnal transition phase the oxygen ratio is at its lowest point in the Dresden Heights-Marseilles section, although much higher there than in midsummer, rises thence slowly to Peoria, and continues on an approximately level line to the mouth of the Illinois. In the spring phase a transition in the opposite direction probably gives somewhat similar results, modified, however, by the spring floods, which are usually much larger than those resulting from the fall rains, and by differences in the antecedent seasonal conditions from which this spring transition makes its start."

"These periodical changes in the distribution of oxygen and carbon dioxide within the stream are, of course, consequent upon seasonal differences in temperature and stage of water, influenced considerably by the upper dam, at Marseilles, and the above descriptions may perhaps need modification to make them applicable to notably unusual years."

The writer has endeavored to give the essential features of this valuable report, but there are other interesting points dealt with which cannot be referred to in the space of a review such as this. The comprehensive character of the investigations made under a variety of conditions and over lengthy periods and on the same river, afford a useful index into what may be expected in Canadian rivers, where dilution is contended to sufficiently purify large volumes of sewage. It would seem from Messrs. Forbes and Richardson's report that in the case of Chicago sewage dilution is either insufficient or it is not effective enough. Without the necessary data it is, of course, not possible to express opinions on this score. Hoping the foregoing will be of some service to your readers, who, if they require further information, should obtain a copy of the bulletin in question, by writing to the Director of the State Laboratory, Urbana, Illinois.

ITALY'S WATER POWER DEVELOPMENT.

The *Scientific American* gives an interesting account of the enormous power plants planned, involving irrigation works, for Southern Italy. It is expected that water storage reservoirs sufficient to produce 50,000 horsepower, can be laid out in the Calabria region; while, in the Sila mountain country, where there is an abundant rainfall, though irregular, throughout the year, four great reservoirs will be used, the largest to contain 5,000 million cubic feet of water. It is planned to erect at the outset a 50,000 horsepower turbine electric plant, from which part of the current generated will be utilized by the nitrate of calcium fertilizer works, and the remainder will be transmitted over long power lines throughout Calabria and surrounding regions. Additional profit is to be gained for agriculture by this new enterprise; for the regular water supply will provide a very satisfactory irrigation system. For the island of Sardinia a somewhat similar scheme is contemplated; and for the Cagliari plain the water of the River Tirso, which is to supply a reservoir of 10,000 million cubic feet for use with a 15,000 horsepower hydraulic plant, will provide irrigation, as well as power in the place of coal for the use of the numerous mines of the country.

THE REJECTED McGREGOR LAKE SCHEME FOR OTTAWA WATER SUPPLY.

As announced on page 78 of last week's issue, the city of Ottawa has decided to adopt the scheme advanced by Sir Alex. Binnie, for the supply of water from Thirty-One Mile and Pemichangaw Lakes. *The Canadian Engineer*, in its October 16th issue, outlined the water situation in Ottawa and published the important features of the report upon the recommendation of which the City Council decided, on October 17th, to act.

This report also included the results of an investigation of the McGregor Lake series as a source of supply. By the term "McGregor Lakes" are known a large number of lakes which are situated at distances varying from about 15 to 30 miles to the north of Ottawa and lying about mid-way between the Gatineau and the Lievre Rivers. They are small when compared with Thirty-One Mile Lake, the largest being McGregor, which has an area of 2.13 square miles, or about one-ninth of the area of Thirty-One Mile Lake. Mr. Hazen in his report, dated the 10th of May, 1910, gave a table setting out the various lakes, 37 in number, and their areas, which either discharge into the Blanche River by way of McGregor, or the waters of which can easily be diverted into that lake:

McGregor, with an area of 2.13 square miles,
Wakefield, with an area of 1.47 square miles,
Grand, with an area of 1.37 square miles, and
St. Germains, with an area of 1.12 square miles, are the only lakes of any size; the others enumerated varying from about a square mile to a few acres in extent. The drainage area which contributes, or which can economically be made to contribute, to the water flowing from McGregor Lake into the Blanche River amounts to about 94 square miles. Taking the same figure for average rainfall, as in the previously described Pemichangaw Lake scheme, viz., 37 inches, and assuming the same figure for evaporation from which the figure of 13.6 inches is arrived at as representing the run-off during the three driest consecutive years as being applicable to both Thirty-One Mile and McGregor areas, the report estimates, a figure of 51,000,000 gallons per diem as the yield of the drainage area.

As in the previous case, the ground surrounding the lakes is for the most part rocky and covered with trees, but the hills surrounding Thirty-One Mile Lake rise to greater altitude, and far more clearing has been done around McGregor Lake and Wakefield Lake, the resident population being given as between 7 and 8 persons per square mile. The effective storage in improving the purity of the surface water and in bleaching and removing the color is now very generally recognized, and it is important in this respect to bear in mind that whereas the total water area of Thirty-One Mile and Pemichangaw Lakes amounts to 24 square miles, the total area of the four principal McGregor Lakes amounts to only 6 square miles. Thirty-One Mile and Pemichangaw are also lakes of great depth, whereas there is a considerable area of comparatively shallow water in the McGregor and Wakefield lakes. Taking these circumstances into consideration, the report suggests that the water stored in Thirty-One Mile and Pemichangaw Lakes would be superior in quality to the McGregor Lake water, and such is unquestionably the case.

Whereas, the water of the former lake was bright and clear in the early part of September, the water of McGregor contained a considerable amount of amorphous matter in suspension. The McGregor Lake water

is, of course, very much superior to the Ottawa River water, but in order to render it as bright and clear at all times of the year as the Thirty-One Mile Lake water filtration would be necessary. If the McGregor Lakes are adopted as a source of supply, that the farms and residence surrounding the lakes should be purchased, as there are far too many possibilities of infection of the water taking place. In fact, the population in the drainage area is considerably higher than that of the basin of the Ottawa River.

Filtration.—The best way of treating the McGregor Lake water would be by means of mechanical filters. The cost of such filters works out at about $20,000 per million gallons treated per diem, when the filter house and various pipe work is included. It is very difficult to say what amount of coagulant would be required, but a very small quantity would be sufficient, seeing the character of the water, and it has been assumed that one half grain of sulphate of alumina per gallon would be sufficient as a yearly average. The working expenses of the filtration plant would exceed $19,000 per annum for an output of 25,000,000 gallons per diem. The loss of head through such filters is considerable; twenty feet was allowed in the estimate for that purpose. This had an important bearing on the lay-out of the scheme.

Method of Collecting and Storing the Water.—As in the previous case, a service reservoir was included in the scheme, and the most suitable site for the service reservoir for the McGregor Lakes scheme would be the same as for the Thirty-One Mile Lake scheme, as there is no other area of ground at a suitable elevation near the city. The present water level of McGregor Lake is about 466 feet above datum, and if the water were filtered 20 feet would be lost, which would reduce the pressure to 446 feet above datum, or to about the same level as the top water level of the service reservoir, namely, 445 feet above datum. It was, therefore, proposed to construct a dam at the outlet of McGregor Lake, where an excellent site exists, so as to raise the water in that lake to give the necessary head. The distance between McGregor Lake and the service reservoir is 78,500 feet, and if the same hydraulic gradient is taken as for the Thirty-One Mile Lake project (1 in 1960), a pipe 54 inches in diameter would be sufficient, the loss of head in the pipe when discharging 25,000,000 gallons a day amounting to about 40 feet. Adding to this the loss of head in the filters, namely, 20 feet, the total loss between the storage and the service reservoirs would amount to 60 feet, and the minimum draw-off level at McGregor Lake would be 445 + 60 = 505 feet, which would mean raising the level of the present lake 39 feet. Assuming McGregor Lake can be raised 50 feet, the top 11 feet could be used for storage.

Here, however, arose a difficulty. At some future date it would be necessary to increase the supply, and this storage would no longer be sufficient. Another excellent site for a dam exists at the outlet of Double Dam Lake, which would store water in Grand Lake. This site would be under water if McGregor Lake was raised 50 feet, and, therefore, it would be necessary to construct, at all events, that portion of the dam which is below water as part of the first instalment. It would, however, be necessary to complete the dam right away for several reasons:—

1. So as to avoid the possible chance of pollution of the water supply of the city by the large body of workmen who would have to be employed in its contruction.

2. It would assist in the storing of flood water, which would otherwise have to run to waste, and would delay bringing the scheme into operation.

3. The water which now flows from Grand Lake into McGregor by way of Double Dam Lake is utilized to develop electric energy to work the air-compressing plant for the Blackburn Mines.

It would either be necessary to compensate the owners for depriving them of this power or to provide an alternative. By constructing the dam this power could readily be given by means of the water held up at the higher level in Grand Lake discharging into McGregor. For these reasons the estimate provided for the supply of 25,000,000 gallons per diem, a second dam at the outlet of Grand Lake which will raise the water in that lake to 550 feet above datum, and would flood back into Wakefield Lake, raising the level of this lake 11 feet. The effect of the works outlined above would be to flood a very large area of land now under cultivation. In making comparison with the Thirty-One Mile Lake project it must be borne in mind that storage is there provided for the full yield of the drainage area for 81,000,000 gallons a day.

Pipe Line.—After leaving the McGregor Lake the pipe line would follow the same route as that proposed by Mr. Hazen for about 5 miles; it would then turn to the west, crossing the Gatineau River about a mile north of Wright's Bridge, and would then proceed in a south-westerly direction to the service reservoir, the total length of the pipe line being 78,500 feet. The estimate assumed that the Gatineau would be crossed by means of suspension bridges having a total length of about 1,000 feet divided up into three spans, the pipes being protected from frost as already described. The first four or five miles would involve a good deal of rock-cutting but the effect of raising the level of the outlet gives an easier route just after leaving the lake, and enables pipes to be carried the whole way up to the dam. The remainder of the route is through fairly easy country as far as the service reservoir. This reservoir and the pipe line forward to the city would be the same as for the Thirty-One Mile Lake project, and, therefore, calls for no further description.

Provided the work were put in hand at once it might have been possible to bring in the water from this source by about the year 1917. The sites for the proposed dams to impound the water of this watershed were not so favorable as that of Mitchel's Dam, where the waters of Thirty-One Mile Lake would be impounded. For this reason they would take longer to construct, although the pipe line itself would be shorter.

Annual Working Expenses.—The working expenses of this scheme would be higher than for the Thirty-One Mile Lake scheme on account of the filtration expenses, which are given as being $19,000 per annum. The aqueduct being shorter would mean a saving of about $5,000, and the total working expenses would amount to approximately $29,000.

The following estimate was based upon the proposals as above:—

Head Works.

Dam to raise McGregor Lake to 515 ft. level with valve tower, etc.....	$ 327,500
Dam to raise Grand Lake to 550 ft. level with outlet works	260,000
Clearing and burning area to be submerged	38,400
Road diversions, with bridges and culverts	80,000
Diversion of water from St. Germain, Battle and Rheaume Lakes	25,000
Plant for Blackburn Mine	25,000

Aqueduct.

54-in. steel main 7-16-in. thick, from McGregor to service reservoir—78,500 lin. ft.	1,448,325
Small stream crossings	9,500
Bridge on Gatineau River	130,000

Service Reservoir and Mains.

Service reservoir (as in Thirty-One Mile Lake scheme)	260,210
51-in. steel mains to city (as in Thirty-One Lake scheme)	1,101,120
Small stream crossings (as in Thirty-One Mile Lake scheme)	20,000
Bridge on Ottawa River (as in Thirty-One Mile Lake scheme)	180,000

Filters.

Filtering plant	500,000
Total for works	$4,395,055
Add 15 per cent. for engineering and contingencies	659,258
	$5,054,313
Land and lakes, compensation, etc.	2,000,000
Total estimate	$7,054,313

The entire report concluded with a comparison of the two schemes, as to their relative merits, as follows:—

	Thirty-one Mile Lake and Pemichangaw Lake	McGregor Lakes
(1.) Total quantity of water available.	81 millions gallons per diem.	51 million gallons per diem
(2) Quality of the water.	Bright and clear.	Somewhat turbid contains amorphous matter in suspension
(3.) Filtration.	Not required.	Required.
(4.) Aqueduct	235,000 ft. 54" pipe; 64,000 ft. 51" pipe;	78,500 ft. 54" pipe; 64,000 ft. 51" pipe.
(5.) Service reservoir.	To hold 295 million gallons.	To hold 295 million gallons.
(6.) Pressure (static)	118 lbs. at Pumping station.	118 lbs. at Pumping station.
(7) Estimated cost.	$7,985,200.	$7,054,313.
(8) Working expenses.	$15,000 per annum.	$29,000 per annum.

Referring again to the intention of the city to go ahead with the former scheme, which has been approved by the Dominion Government and by the Ontario Board of Health, preliminary arrangements for the early commencement of work are being made.

ALASKA RAILWAY DEVELOPMENT.

The British, Canadian, and United States Governments are considering a proposal, it is stated, to construct a railroad through Canadian territory to join Alaska to the United States. The proposed railway would be of obvious commercial value. Sir Richard McBride strongly favors the scheme, and is shortly to visit Washington to discuss the question with the Administration. It is proposed that branch lines should be built to connect the main line with the harbors of Alaska. It is believed also that the projected line will stimulate railway building throughout Alaska, which is required to connect Cordovia and Seward, the two leading ports of Southern Alaska, with the interior and with the Dawson line.

BUSINESS METHODS IN CONSTRUCTION WORK.*

By James L. Stuart,
Constructing Engineer, Pittsburgh, Pa.

PERHAPS there is no business which responds more quickly to what is termed "modern methods" than does the average piece of construction work. Certainly, there is no business with more diversified interests and trades connected with it than the modern structure, be it railroad terminal, factory, office building, hospital or hotel.

It has not been more than twenty years, at most, since the construction of buildings was left entirely to practical men who had themselves worked up from positions as artisans or laborers to positions of leadership in constructional lines. Some of these leaders in the past were most talented and even brilliant, but they did not bring with them into the business, excepting in rare instances, the methods of the trained engineer or the progressive business man, their principal assets being nervous force, executive ability and practical knowledge of the building trades. However, as building construction became more complex and of greater magnitude, the necessity of trained men who understood the engineering problems and who appreciated the application of business methods necessary to bring "order out of chaos" became more apparent, and now both engineering knowledge and modern business methods are most necessary to get proper results as to economy and quality in all of the larger undertakings.

In order to successfully construct a building, it is necessary that one should anticipate each step in the progress of its developments and outline a complete system for its erection, including the various steps from the time the drawings are received from the engineer or architect until the building is turned over completed to its owner. The first step in such a process is to make a complete estimate of the cost of the structure from the drawings and specifications, including every item mentioned in the specifications or shown on the drawings. In addition to this there are other small items which are not mentioned in the specifications, but which are necessarily a part of the cost of the building and should be included as such. Under the latter are such items as the cost of administration, liability insurance, temporary buildings, expediting, tools and machinery and numerous smaller items. These estimates of cost were originally made up by the contractors themselves and were but approximations as compared with the present method of compiling them. In the later method every advantage is taken of the prevailing market prices when the estimate is made, of the conditions of the labor market, the physical condition under which the work is to be done, and the season of the year. In a properly prepared estimate the unit prices should vary on each individual piece of work, whether figured at the same time or not.

After the estimate has been made of the total cost of the building—and I think an estimate should be made of every building whether the work is to be let on a lump sum contract, cost plus a fixed sum, or on a time and material basis—the next step is to make up a time schedule allowing fixed periods of time for the completion

*From a paper presented Jan. 14th, 1913, to the Cleveland Engineering Society.

of each part of the building. This must be done most carefully, as on this schedule is based the dates of completion of the different contracts for material and the contracts with sub-contractors for furnishing such portions of the work as are not to be executed by the general contractor's force in the field. This time schedule is made after a thorough study of the drawings, the site of the new project and a familiarity with the estimate which, as I have said before, gives the quantities of the different kinds of material and assists in estimating the length of time required to complete the various stages of the work.

After the estimate and the time schedule are completed and the contracts for material and labor have been entered into, the real work begins.

A dozen or more sets of drawings are procured from the architect or engineer, a copy of same placed on file in the main office of the builder, one copy sent to the job office and the others distributed among various sub-contractors who have to make up their shop drawings and prepare certain materials to be later installed in the building. A careful record must be kept of these drawings and to whom they are addressed and the date on which they are sent. While the various departments of the main office keep thoroughly in touch with the work in the field and the material in preparation, at this point, if the work is of sufficient magnitude, it is turned over to one particular member of the contractor's force, preferably a trained engineer, whose duty it is to keep in thorough and constant touch with all the drawings and all of the correspondence. He also has access to the files of the sub-contractors, contracts, contracts for materials, the original estimate and all other information pertaining to that particular piece of work. It is then his duty to follow up the sub-contractors in the preparation of their shop drawings, the submitting of same to the architect for approval, the ordering of materials by the sub-contractors, and the progress being made through the fabricating shops and mills. This following-up process is part of his daily routine and from time to time reports are made to the superintendent in charge of the actual field work to enable him to know when the material is going to be received, when the sub-contractors will have their men and material on the job, all of which enables him to shape up the field work so that certain portions of the building will be ready for certain sub-contractors at a fixed time. It is also his duty to keep track of the change orders and the changes made in the construction of the building, whether it be addition or subtraction. You can readily understand how necessary it is that all sub-contractors should be advised of changes, for often when they are conceived in the mind of the owner, their interference will be more far-reaching than he or anybody else anticipated.

A proper executive organization to do the field work is most important. It is far better to have too much assistance in the field than too little. First, there must be a superintendent who possesses rare abilities as an executive, who understands drawings and specifications thoroughly, who has had wide experience in building work and who has a knowledge of the different trades so as to be able to anticipate far in advance of his requirements. Above all, he should be able to create in those working under him, including the workmen employed by his department, and foremen and workmen of the different sub-contractors, an enthusiasm in their work, a desire to see it grow steadily, and to do it in the most substantial manner possible. If the work is of sufficient magnitude he should have an assistant superintendent, or possibly two or three of them, a large enough clerical force to do the timekeeping, and to keep an accurate cost record, and he should segregate the cost of the additional work which was not originally provided for. All of this work, if permitted to lag for even a day, becomes most complicated, and if not accurate, its value is entirely destroyed. In addition to this it is the duty of one of the clerks to send to the main office each day an accurate and concise report of what has been done during the day, the state of the weather, temperature, etc. As the building nears completion, work in the main office lessens and it is usually an excellent idea to have the man in charge of the particular job in the main office to get in actual touch with the building and assist the superintendent in picking up the loose ends and getting each trade completed as rapidly as the progress at the building will permit. This man (from the main office) is thoroughly familiar with each trade, knows just what changes have been made in the work, has a splendid knowledge as to how long it will take each trade to complete its work, knows the difficulties under which each has been laboring and can finish his "following-up process" from the field more intelligently than if he were to remain at the main office.

The cost of a piece of work is always of interest. The estimating department has access to the daily and weekly cost reports which are compiled in the accounting department, and from these they can compare and report to the proper person whether or not the work is being done each day or each week within the amount allowed for same in the original estimate. If the work is not being done within this cost and if the unit prices vary considerably from day to day investigation is at once made at the building to ascertain the reason for such fluctuations, to advise the superintendent of the discrepancy and to see if ways and means cannot be found to bring the cost within its proper allowance—the estimate having been based on the cost of similar work under the same conditions, the proper average should not vary greatly from the amount allowed in the estimate.

Some time during the latter part of May, 1910, a large manufacturing plant in Pittsburgh, covering approximately fifteen acres, was almost totally destroyed by fire. All of the buildings were brick, some with wood trusses and slate roofs, but the greater number were constructed with steel frames and cement tile roofs. The fire in and around these steel structures was so intense, however, that most of them collapsed of their own weight and were but a mass of twisted steel, broken cement tile, brick and mortar, all of which it became necessary to remove in order to reconstruct the plant. We first received orders to clear the site and subsequently were instructed to proceed with the reconstruction of the buildings. Fortunately, the power plant had not been greatly damaged and, as a large portion of the plant had been driven electrically, we were able to get sufficient current of high voltage to use in cutting up, or burning apart, the collapsed steel frames, all of which was so badly damaged that it was loaded on cars and sold as junk.

After the site was cleared we began excavating for the new foundations, starting on the buildings that would be required first and those in which the greatest amount of machinery was to be installed. This scheme was followed so as to enable the entire plant to be completed at about the same time. It was the desire of the manufacturing company to commence manufacturing about the

first of October, or earlier if possible. The key to this particular situation was to get the steel, of which there was about 4,800 tons. After consultation with the operating and executive departments of the manufacturing company, the order in which the different buildings were to be completed was decided on and the dates were fixed for the delivery of the steel for each building and were included in the schedule for the completed buildings. The structures were quite simple, similar to most of the modern factory buildings, but in order to live up to our schedule we knew we must keep continually in touch with the Bridge Company and see that nothing was permitted to lag or be left undone in order to make the deliveries as they promised. Our expediter was put in charge of the job at once and during the first month spent most of his time between the order department of the Bridge Company and the steel mills at which the plain material was being rolled. After the last of the orders for the plain material had been sent to the rolling mills he devoted his time more particularly to the drawing room of the Bridge Company and reported daily just what progress was being made in designing, detailing and checking, the number of draftsmen employed and the progress made on each building. At times it was found that the checking department was overbalanced by the detailing department and that the designing department was not turning out sufficient work to keep the draftsmen doing the detailing and the checkers busy. This was adjusted by numerous meetings between the Bridge Company, the executive department, the manufacturing company and ourselves. It might be said here, that the principal requisites of an expediter are, a thorough knowledge of the work to be performed, a pleasant personality and the ability to interest the people who are actually doing the work—in this case, the men who made out the mill orders, the draftsmen, different foremen in charge of the rolling mill and the foremen in the fabricating shop. All should be made to feel that their interests are parallel and that what is good for one is good for all. As soon as the drawings for one of the buildings were completed, we saw that this work was put in the shop at once where someone had already seen that the plain material was delivered, and that no time was lost in fabricating and shipping same.

At times during the preparation of the drawings it was found necessary to urge the Bridge Company to employ additional men in all departments. This required considerable tact and force as, naturally, the heads of the different departments do not care to have their routine changed or, as they express it, "meddled with." This phase of the difficulty can be overcome only when it is possible to get sufficient interest aroused in that particular piece of work. When the work was started our expediter received from the rolling mills from which he knew the steel was to be furnished, a list of their daily rollings and we saw to it that certain materials were gotten in on the dates at which the first rolling of that particular material was made. This saved not a little time and we were able to get all of the plain material delivered before the shop drawings were entirely completed on the first building. The meetings between the heads of our department and the heads of the Bridge Company were most useful. Our expediter was usually on hand and we were able to discuss the progress made since the last meeting, the condition of the work in the drafting room and shop, and to devise ways and means for overcoming any obstacles that had arisen either due to lack of men or want of materials.

The steel was erected as fast as the work was gotten out of the mill, fabricated and delivered. We insisted on its being fabricated in sequence so that any materials delivered at the building could be immediately put in place. It had been previously decided at which end of the building the work would commence and our superintendent in the field was advised of this fact and was also kept in thorough touch with the progress of the different stages of the steel. As the cars of steel were loaded and shipped out, they were put in the hands of the tracing department of the manufacturing company and our own tracing department as well, and shipments were followed up until they were finally landed at the site. Our tracing department had, prior to this time, made the acquaintance of the different employees of the railroad through whom the records of the movement of the cars was to pass, as well as those who had direct charge at the transfer points. After the steel had been delivered the rest of the work was a mere question of brick, mortar, sand, gravel, cement, window frames, sash, roofing material and sufficient workmen. Of course, there were large quantities of all these materials required and in order not to delay the work it was imperative that certain amounts of same be delivered and put in place prior to the delivery of the steel.

This same method was applied to the construction of the Statler Hotel, Cleveland, except that the work was much more complicated and required many more details. There were approximately ninety sub-contractors and material men in and around the building from almost the day it was started until its completion, and it required a great deal of patience, perseverence and hard work to get the different trades to dovetail into each other throughout so that those who did the preparatory work would be completed and away in time to permit the finished material to be erected in a proper and substantial manner. On the Statler Hotel we found it necessary from about the first of June until a few days before the building was turned over to Mr. Statler, to insist on daily meetings of all of the sub-contractors on the work, together with the architect's representative and others interested in the building. At these daily meetings each trade was taken up separately with the principal representative of that particular trade and the representatives of all the other trades present. He was asked regarding the progress of his work and was told to state whether or not he was being retarded by any of the other trades. If it was found that he was being hampered he was made to state explicitly and in detail to what extent and how.

The advantage of having all of the sub-contractors together at one time can readily be seen, as it eliminated innumerable quarrels between the foremen of the different trades and many misunderstandings which invariably arise due to the fact that the workmen and foremen are not always capable of expressing their troubles in an intelligent manner and, when they are busy, many times do not take the trouble to express themselves at all. It was rather hard to get them to continually attend these daily meetings, as they were held in the evening after they were supposed to be through with their work. We always tried to make the meetings as pleasant and as short as possible and never permitted ill-feeling to exist between the several trades arising from the discussions at the meetings. A typewritten report of each meeting was posted up on the general bulletin board so that each of the sub-contractors would have access to same during the following day.

The Canadian Engineer

ESTABLISHED 1893.

ISSUED WEEKLY in the interests of CIVIL, MECHANICAL, STRUCTURAL, ELECTRICAL, RAILROAD, MINING, MUNICIPAL, HYDRAULIC, HIGHWAY AND CONSULTING ENGINEERS, SURVEYORS, WATERWORKS SUPERINTENDENTS AND ENGINEERING-CONTRACTORS.

Present Terms of Subscription, payable in advance.

Postpaid to any address in the Postal Union:

AGITATION FOR PROVINCIAL DIVISIONS OF THE CANADIAN SOCIETY.

British Columbia members of the Canadian Society of Civil Engineers are strongly advocating a change in the by-laws of the Society to enable them to establish a provincial division, whose jurisdiction shall extend over the entire province, its membership comprising all members, whether connected with existing branches of the Society or not. The movement has become prominent during the past year, and a strong effort will be made at the annual meeting of the Society in January to present convincing arguments for its adoption. On page 639 of this issue appears an account of a joint meeting recently held by the Vancouver and Victoria branches. A full discussion of the question was indulged in and a resolution adopted, which has been included in the article. Briefly, the necessity for such an organization was emphatically urged, and it is understood that other branches of the Society concur pretty generally with the contention prevailing on the Pacific Coast.

This expression of a keen desire for more activity and influence on the part of the Canadian Society of Civil Engineers, coming as it does from within, is one that should be supported, as upon it hinges several vital factors. One, for example, is the necessity for the establishment of a better relation between the Society, as a representative body, and the grounds for, and extent of, the responsibilities of the engineering profession in its position in the van of the forces that are furthering the development of the country. The engineer has been rightly termed the advance agent of civilization, and with his work is associated a vast personal responsibility which, in case of failure, is all his own—wherein exists a noticeable difference between professions. If his work is a success, the engineer may receive a little credit; if it is not, he is held accountable. Disparagement is inevitable, praise is probable.

Be that as it may, the profession is being moulded by the Society and, with the illimitable outlook for engineering activity in Canada, it is timely that measures should be advanced to substantiate the grounds for the responsibility which falls to the Canadian Society of Civil Engineers in the country's development. An unsuccessful piece of engineering construction stands in the eye of the public a glaring monument to incompetency. Nor can it be denied that the profession falls for a goodly share of derision as well as the unfortunate individual. There is work for the Society in the prevention of incompetency in engineering. The formation of provincial divisions, with a grant of sufficient leeway to foster the interests of engineering in their own provinces, is a plan worthy of consideration.

THE PAVING "DETERMINATOR."

Webster defines the word "determinator" as one who fixes, settles or decides. In that sense the word certainly cannot be properly applied to the machine that was labeled "Paving Determinator" at the recent American Road Congress. Two large, heavy wheels were driven around a two-foot circular path, constructed for three-quarters of the way of concrete, the remaining quarter of the circle being of vitrified brick. The machine was driven at high speed night and day for a week.

Both materials stood the "test" remarkably well. Like all abrasion tests, however, it differed so much from practical, working conditions that little importance can be attached to the results. It is doubtful whether any entirely successful abrasion test has ever been made with any material. They have been frequently tried by the large laboratories such as Capt. Hunt's and others, but have always been disappointing. Chilled cast iron vs. forged steel, enamelled tile vs. other floorings, brick vs. concrete—in all of these tests conditions have been created by the test itself that are not met with in actual practice. Heat is created and a grinding action induced instead of a rubbing action; or a kneading effect is produced that in practice is eliminated by frequent scrubbings and cleanings; or the expansion and contraction, due to gradual differences in temperature throughout the seasons, cannot be similated: or any one of a dozen of other discrepancies between the test conditions and actual working conditions make the test of little value. Moreover, no two brick roads are the same, nor are any two concrete roads. It would, therefore, be the sheerest folly to condemn either brick or concrete as the result of an abrasion test on a few feet of each pavement. Local conditions, prevailing prices and some explicit suitability to the particular work in hand, will govern the choice of the engineer far more than the results of the "paving determinator."

EDITORIAL COMMENT.

The proposal of the Hydro-Electric Power Commission to furnish electrical power to Owen Sound from Eugenia Falls, was accepted by the town council on Monday last. The commission's investigation into the stream flow has been of a convincing nature as far as supply is concerned, which point has been a bone of contention for two years. As stated in these columns early in September, the commission found 1,400 h.p. available at little cost, or with the use of a storage basin 4,000 h.p. Thus assured, Owen Sound has expressed its willingness, and the work of power development will proceed. Construction will commence at Eugenia Falls early in the spring, and power will likely be turned on before 1915.

* * * *

The Ontario Highway Commission has arranged a series of meetings throughout older Ontario at which representatives from surrounding municipalities will gather, voice their needs, and acquire from the Commissioners a clear understanding of the good roads movement. The sessions are educational in motive and are to be strongly commended. No doubt the Commission will be the recipient of many potent and valuable suggestions, as the individaul demands of the different localities accumulate. Likewise the representatives will receive an insight into the magnitude of the undertaking and the advisability of bringing strong argument before the Legislature next spring for the furtherance of the needful improvement. Meetings are scheduled for: Ottawa, Oct. 28th; Belleville, Nov. 4th; Hamilton, Nov. 11th; London, Dec. 16th; Toronto, Jan. 13th, 1914, and Guelph, Jan. 20th, 1914. The older part of the province has been divided into sections with these cities as centres, and all counties are to be represented.

THE EFFECT UPON DESIGN IN REINFORCED CONCRETE OF ALTERATIONS IN THE MODULAR RATIO.

THE London (Eng.) City Council has recently drawn up a revised code of regulations for reinforced concrete buildings, supplanting those which were adopted in 1911, and which were subjected to much criticism from structural men, the chief claim being that of inadequate and incorrect assumptions in the matter of designs. The subject has received wide attention during the past season, largely owing to the belief that the new regulations, as were then in the stages of preparation, were again being based upon wrong assumptions, viz., that the concrete takes no tensile stress, and that the stress-strains line of concrete and steel, acting in conjunction, is straight. The subject received a thorough treatment by Mr. Percy J. Waldram, F.S.I., M.C.I., in *Engineering*, (issues of June 13, 20, and 27), to which the reader may very profitably refer. The articles discuss the previous regulations, point by point, and show the value of drawing up regulations that will assist in, rather than retard, the application of sound engineering principles by providing for periodical revisions or for the alternative use of future modifications of a theory which may at present be used largely, but tentatively.

The same writer again takes up the subject in *Engineering*, for September 26th (since the revised code was drawn up), and calls attention to the lack of elasticity in the obligatory use of the purely theoretical formulæ specified in the new regulations, many of which are well known to be based upon inadequate data and upon hypotheses which are patently incorrect, even though the errors may be negligible.

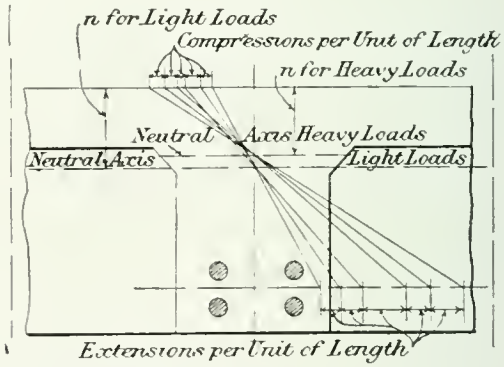

Fig. 1.—Determination of Position of Neutral Axis by Extensometer Measurements.

There are many phases of the discussion that will be found to apply with almost equal force to regulations in America respecting reinforced concrete construction, and the following extracts from Mr. Waldram's paper should prove of value.

It is unfortunate that no machinery is provided (in these new regulations of the London City Council) for the automatic revision of the code at stated periods, in order that advantage may be taken of our rapidly increasing knowledge of a new and intricate subject. These matters will doubtless be fully considered by the institutions to whom is entrusted the statutory duty of criticizing the code. With regard, however, to the extensive alterations which are made in the permissible stresses and the modular ratio, there is no small danger

of full consideration being hampered by lack of data upon which calculations showing their effect can be worked out readily.

In the following article an attempt is therefore made to supply such necessary machinery without in any way attempting to anticipate any conclusions which the institutions may arrive at with regard to the desirability or otherwise of the alterations of stresses and modular ratios now suggested by the Council. These alterations appear at first sight to be merely prudent, even if somewhat excessive, concessions to a not unnatural distrust of a method of construction based upon intricate theory and comparatively new to many designers. But when carefully examined it will be found that their cumulative effect upon the design of actual

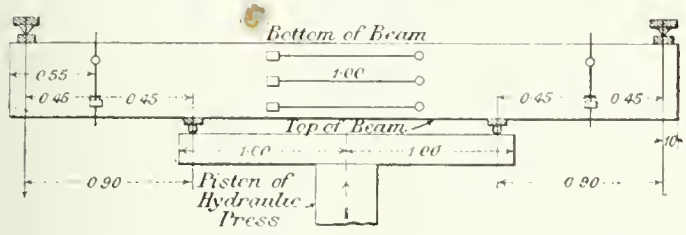

Fig. 2.—Typical Arrangements for Test of Beams, Adopted by French Government Commission, 1900 to 1906.

members would be very severe, and, in fact, almost revolutionary. The new material would by them almost certainly be barred physically by excessive weight, as well as economically by excessive cost, from undertaking many tasks which are well within its ordinary field of employment; and it would appear to be no exaggeration to say that very few of the large buildings now being erected or completed for Government or public authorities would come even within a reasonable distance of complying with the proposed code.

It will be found that mixtures richer than the stereotyped 1:2:4 are so severely discredited that in all work carried out under the code they will of necessity be penalized out of existence. The risk of making concretes too rich in cement would scarcely explain such drastic treatment, and one can only conclude that the Council feared the contingency of district surveyors being imposed upon by approving calculations for rich, strong concretes in situations where ordinary 1:2:4: mixtures would subsequently be substituted in the district surveyor's enforced absence. There may be more cogent objections to stronger mixtures; but considering the great economies in weight and cost which can often be effected by their use, and the importance of eliminating unnecessary dead weight, it is at least open to question whether they should be prohibited for no better reason than that district surveyors have not been given adequate discretion to insist upon the necessary supervision of mixing.

Not only are the permissible stresses on rich concretes severely cut down, but the modular ratio is also lowered in respect of them; the net result being, as will be seen later, a virtual permissible stress actually lower than that of the poorer 1:2:4 mixture, thus preventing a designer even from calculating for 1:2:4 concrete, and subsequently carrying out the work in a stronger and more expensive material. The tasks which are imposed upon the concrete of a reinforced member, in addition to that of resisting the bending moments, are so numerous, so complex, and so important, that many prudent designers might still desire to enrich their mixtures, in spite of the increase of dead weight and cost which would be incurred by doing so under the proposed code. Any such desire to strengthen a constituent whose relative weakness is universally admitted would in the vast majority of cases be promptly checked by the stipulation that new values of the fundamental modular ratios must be used whenever rich concretes are employed. To comply with this regulation the user of rich concretes must either calculate at interminable length, or else recompile, at least twice, the whole of the tables, data, or diagrams which he ordinarily uses; and the district surveyor who checks his calculations must do the same. No one who has attempted, even in part, the enormous labor involved by such a task would care to undertake it unless he were assured that something like reasonable finality had been reached with regard to the values specified. But we have no means of knowing whether these are based upon reliable data, compiled by scientists of standing, upon observations of the behavior of actual beams under load, or are merely deduced from the results obtained by subjecting plain specimens of rich concretes to evenly-distributed compression. Such specimens would certainly act quite differently under flexural stress in a beam, and probably still more so if the beam were reinforced.

Members under Flexural Stress.—In any member of reinforced concrete the proportion of the total work done which is borne by the concrete and by the steel reinforcement respectively is determined not by the relative ultimate strength, but by the relative stiffness of the two materials. In other words, it is governed by the ratio existing between the modulus of elasticity of the steel E_s, and that of the concrete E_c, and known as the modular ratio $\frac{E_s}{E_c}$, or m.

The calculations of the designer in reinforced concrete depend absolutely upon the accuracy of his forecast of the relative stiffness of his materials at working loads. Such a forecast can only be obtained by noting the behavior of his materials when in double harness in a beam. The observer must be prepared to find that it will vary at different stresses, and that direct compression and tension tests on different specimens are no criterion of what will happen when the materials are subjected to the varying intensity of stress which is imposed upon the fibres of a beam section under flexure.

The modular ratio at different stresses can be obtained by measuring the relative extension and compression of the concrete fibres and the steel, and thus locating the neutral axis, as in Fig. 1. Then for any given position of the neutral axis in any beam of given proportions there must be one modular ratio consistent with that position, and also with the formulæ used. Thus in a rectangular section reinforced with a proportion r of tensile rods, if the distance n of the neutral axis from the top of the beam were determined by the ordinary formula in which $n_1 = \frac{n}{d}$

$$n_1 = \sqrt{m^2 r^2 + 2\,m\,r} - m\,r$$

then the value of m would be

$$m = \frac{n_1^2}{2\,r\,(1 - n_1)}.$$

If the beam experimented upon were a T-section of which the proportion of depth of slab to depth of beam were s_1, then the value of m, which would have to be inserted in the ordinary formula

$$n_1 = \frac{s_1^2 + 2\,m\,r}{2\,(s_1 + m\,r)}$$

would be

$$m = \frac{s_1\,(2\,n_1 - s_1)}{2\,r\,(1 - n_1)}.$$

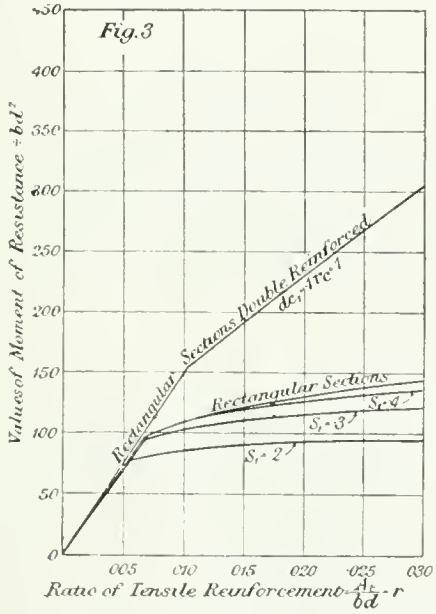
If the section were rectangular and reinforced in tension and compression, the ratio of compression to tensile reinforcement $\frac{A_c}{A_t}$ being r_c, and the depth of the former below the top of the beam were d_o / d, or d_{o_1}, then the value of m would be

$$m = \frac{n_1^2}{2\,r\,(1 - n_1) - 2\,r\,r_c\,(n_1 - d\,c_1)}$$

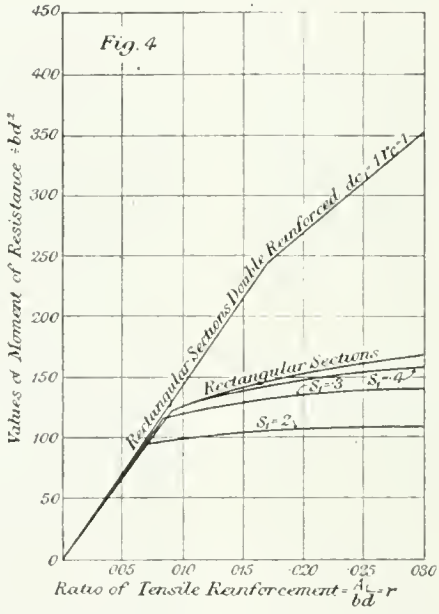
In view of the importance of fixing a correct modular ratio for different classes of concrete, and of the fact that expenditure upon experimental research was specifically authorized under the London County Council General Powers Act of 1909, it is certainly a matter for regret that the Council have not taken advantage of the facilities which thus lay ready to their hand, before attempting to fix new modular ratios in their proposed code of 1913. The ratios specified (11 for 1 :1½ :3 and 8 for 1 :1 :2 concrete) may prove eventually to be correct at working stresses, but engineers will need to be authoritatively assured of this before undertaking the huge task of recompiling their data to agree with them. In fact, to permanently fix them by any means other than carefully digested research ought to be out of the question.

The value attributed to m enters into every one of the calculations required for reinforced concrete. So numerous and intricate are these that practical designers are forced to condense the essential factors into tables and diagrams, the compilation of which represents thousands of tedious calculations. The slightest alteration in the value of m renders the whole of that

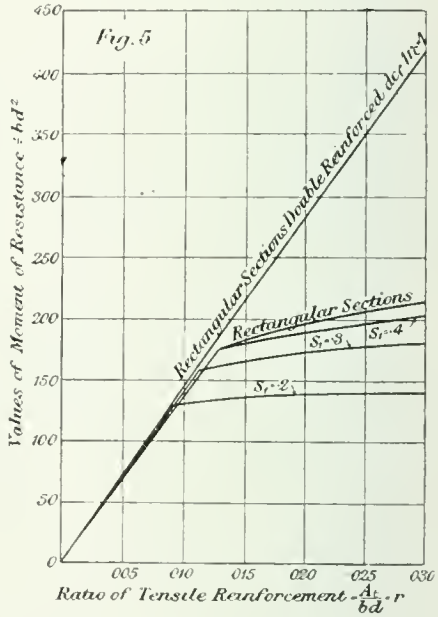
1 :2 :4 Concrete, $c = 600$, $m = 15$



1 :1½ :3 Concrete, $c = 700$, $m = 15$



1 :1 :2 Concrete, $c = 900$, $m = 15$.



The modular ratio for different classes of concrete can therefore be determined without much difficulty by testing a number of beams under different loads and noting the position of the neutral axis shown by extensometer readings of the extended and compressed fibres.

The French Government Commission, which sat from 1900 to 1906, tested a large number of beams and recorded the extensometer readings. Fig. 2 reproduced from M. Nivet's *Cacul de Beton Armé*, show the arrangements adopted for a typical beam. The details of these tests are available, but, unfortunately, they did not include beams of richer concretes.

Until sufficient exact data have been collated of extensometer tests upon beams of rich concretes, T-sections, and of sections reinforced in compression, any value attributed to m for such sections must be at least only conjectural.

labor useless for any purpose for which the altered value of m is to be used. Such alterations can materially affect the calculated strength of beam sections, as is shown by comparing Figs. 3 to 9, in which are plotted the moments of resistance of some typical single reinforced rectangular and T-beams, and of rectangular sections reinforced both in compression and tension.

No examples of double-reinforced T-sections are included, on the ground that under the heavy stresses which demand double reinforcement, it is unwise to consider the material of a relatively thin slab to be a fully efficient working partner in the compression flange; and only such part of it should be taken into account as is consistent with the assumption of a vertically rectangular section. The value of d_o, or depth of centre of compressive reinforcement from top of beam

selected, is $\frac{d}{10}$. Other values could, of course, be added, but allowing for ½ in. of cover in slabs and 1 in. in beams, this value will be found to be a fair average for double reinforced sections. All the types shown are calculated for a permissible tensile stress of 16,000 lb. per sq. in. on the steel, and for a compressive stress of m times the stress on the concrete immediately surrounding the steel.

Figs. 3, 4, and 5 show the unit safe working moment of resistance of beam-sections, calculated with a modular ratio of 15 at the concrete stresses recommended in the Reports of the Joint Committee on Reinforced Concrete of the Royal Institute of British Architects, which stresses are also one-fourth of the ultimate test loads at 90 days, stipulated in the new London County Council code for concretes of the proportions stated.

Figs. 6 and 7 show the same sections calculated with modular ratios reduced to 11 and 8 respectively for the richer mixtures. It will be seen that the effect is a reduction in the theoretical strength, which is more severe on beams with double reinforcement than on those reinforced in tension only. The reason of this is that any reduction of the modular ratio postulates that the stiffness of concrete more nearly approaches that of steel. It, therefore, picks up more readily that proportion of the load which taxes its strength to the full permissible limit, and the capacity of the combination is thus more quickly reached; in double reinforced beams the same excessive zeal of the concrete to overwork itself not only causes it to reach more rapidly the limit of its strength, and calls for more assistance from the compressive reinforcement which is harnessed tandem with it, but also reduces the efficiency of that compressive reinforcement by causing it to work in conformity with a more easily exhausted partner.

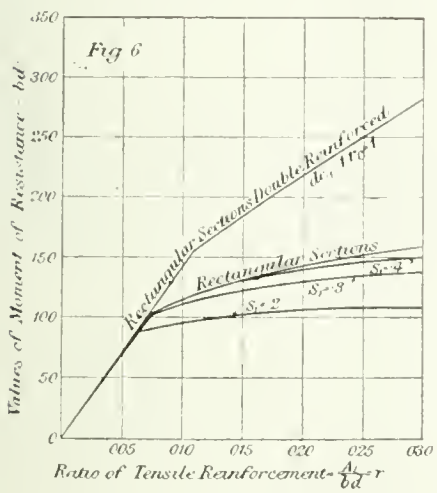
Figs. 8 and 9 show the joint effect of applying to the same sections the reduced modular ratios and also the reduced concrete stresses stipulated in the proposed London County Council code.

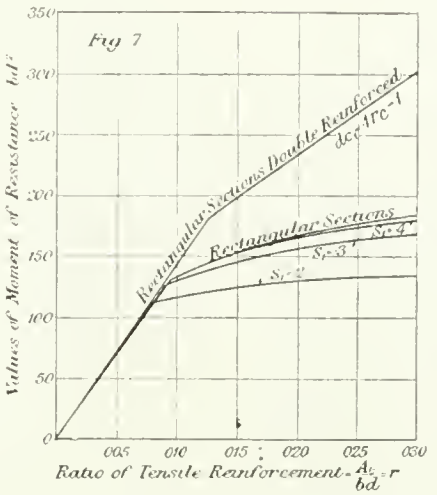
It will be seen from these figures that, in order to comply with the code, the designer must consider his beams to be much weaker if he uses rich concretes than if he uses poorer mixtures. This result is so extraordinary that it would appear to be doubtful whether the compilers of the code really intended to bring it about. The high shearing stresses still permitted by the code make any unnecessary dead-weight more than usually undesirable; and unless very excellent reasons can be shown for the extremely low stresses, and, therefore, very bulky sections involved, it would appear to be reasonable to consider a revision of the present proposals so as to conform with the results shown in Figs. 6 and 7, giving designers the option of either working to reduced modular ratios, or of suitably reducing their working stresses to give the same result.

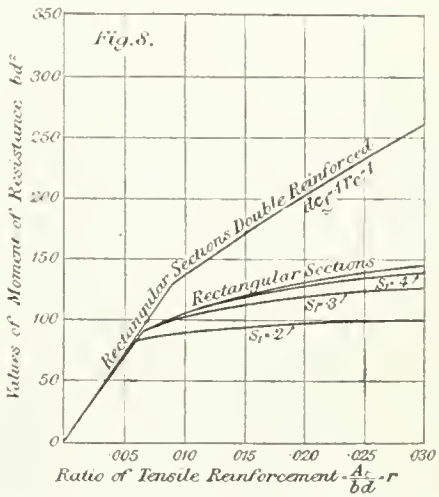
The effect of altering the modular ratio only, leaving the Royal Institute of British Architects' stresses unchanged, is shown in Figs. 10 and 11 in the shape of a percentage reduction in the strength as calculated by the Royal Institute of British Architects' rules, upon which the tables and diagrams generally found in text-books and drawing-offices are based.

At proportions of reinforcement below the economic ratio the stress on the concrete becomes of no importance, and the effect of any alteration of the modular ratio is practically negligible, the slight reduction of tensile stress (or the corresponding increase of nominal tensile strength) obtained by it being too small to take into account. It is necessary, however, to carefully note that the reduction in compressive strength commences at the economic ratio fixed by the lower modular value, and not that fixed by the higher value. The former is indicated by the point on the base line of the diagram from which each graph starts, and the latter by the point at which the graph abruptly changes direction. Fortunately it is possible to fix with but little labor the economic ratios of any class of beam section for any given values attributed to t, c, and m. If, therefore, Figs. 10 and 11 could be expressed in tabular form, the labor involved by altering m could be very sensibly reduced for the great majority of cases arising in actual design. The object of the designer is, or should be, to select the section which will do the work required of it without unnecessary cost in reinforcement. If one type—say, a T-beam in which $s_1 = 0.3$—would require a proportion of reinforcement greater than the economic ratio, then it is cheaper to make the rib wider until it will contain the full triangular area forming the virtual compression

1 :1 ½ :3 Concrete, $c=700$, $m=11$. 1 :1 :2 Concrete, $c=900$, $m=8$. 1 :1 ½ :3 Concrete, $c=650$, $m=11$.







flange of a rectangular section. If this is still insufficient, the designer can most economically increase the deficient compressive strength by going to a still more efficient class, and selecting some suitable double reinforced section. It pays better to use the section properly adapted to any task rather than to over-reinforce an unsuitable one; and the most important result of reducing the modular ratio is therefore the effect which it has upon the position of the economic ratio, which, as the limit of the economical capacity of any type of section is also the practical limit of its employment.

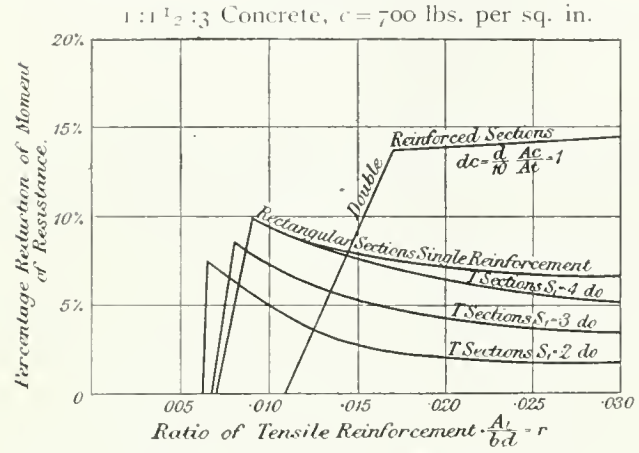


Fig. 10.—Effect of Reducing the Modular Ratio from $m = 15$ to $m = 11$.

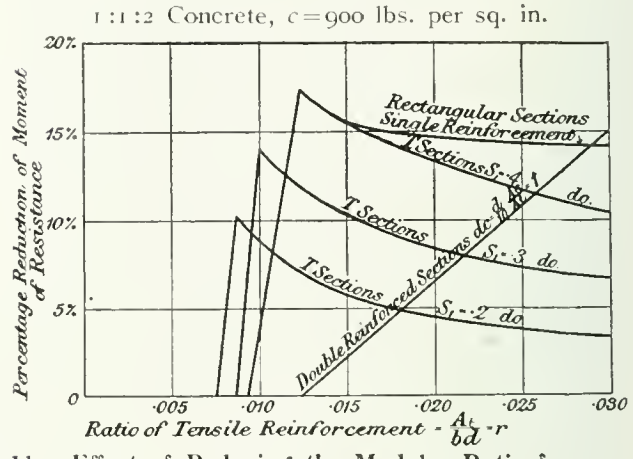

Fig. 11.—Effect of Reducing the Modular Ratio from $m = 15$ to $m = 8$.

Reinforced Concrete Beam Sections.

Strictly speaking, any formula or tabular statement purporting to express Figs. 10 and 11 should allow for the fact that the reduction of the permissible strength necessitated by reducing the modular ratio grows less severe on sections reinforced in tension above the economic ratio, as shown by the dipping curves. But when it is considered how seldom this obtains in good design, probably no great injustice would be done by stipulating, at least as an alternative method of calculation, that the effect of the reduced modular ratios upon the Royal Institute of British Architects' permissible stresses on beams may be taken by calculating as for $m = 15$ and deducting the percentages shown in Table I. The somewhat rare cases of beams reinforced considerably beyond the economic ratio can be calculated specially. The economic ratio could be easily defined as that proportion of tensile reinforcement at which $R_c = R_t$.

The table, like the diagrams, is intended to be illustrative only. Additional percentages would be required for intermediate values of s, in single reinforced T-beams, and, in double reinforced rectangular sections, for values of $\frac{A_c}{A_t}$ greater or less than 1, and possibly for values of d_c greater or less than $\frac{d}{10}$.

Table I.—Showing the reduction, caused by reducing modular ratio below $m = 15$, of permissible moment of resistance of beam sections calculated at the Royal Institute of British Architects' stresses.

Type of Section.	1 : 1½ : 3 Concrete $c = 700$, $t = 16\,000$. $m = 11$.	1 : 1 : 2 Concrete. $c = 900$. $t = 16{,}000$. $m = 8$.
Sections with Tensile Reinforcements Only.		0

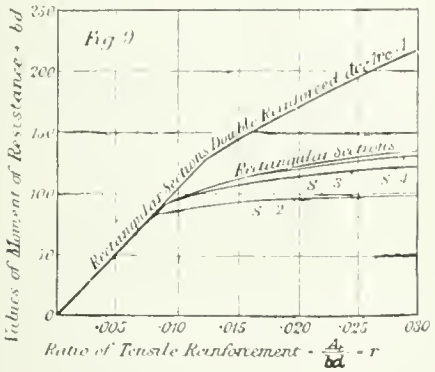
At or above E.R. when $m = 8$	—	23 per cent.

Proportionate reductions to be made at ratios of tensile reinforcements between the economic ratios stated.

Columns Under Axial Load.—The methods of calculating columns under axial loads lend themselves very readily to standardization in straight-line graphs easily calculated and easily drawn for any given modular ratio and stresses. An alternative method of calculation, whereby a percentage reduction may be made from the Royal Institute of British Architects' diagrams, is therefore not so much needed as is the case with sections designed to meet flexural stresses under bending moments. It is, however, very important to note that the effect upon column stresses of reducing the modular ratios does not necessarily tend towards increased safety. In a section subjected to bending moment, the limiting stress on the concrete is almost invariably the vital criterion. In columns, however, it is much more frequently the stress on the steel. The large extent to which the use in columns of hard, stiff steels with high yield-points is advocated serves to show how frequently the designer finds that a given column can only be adequately reinforced by steel which is harder or more willing than the British standard mild structural steel. The effect of reducing the modular ratio is in effect to assume that the

concrete will take a greater proportion of the joint load, so that the steel must necessarily take a smaller share. For any given loading, less stress will be debited to the steel than would be the case if the concrete were credited with a relatively lesser degree of eagerness to pick up work. If the modular ratio be fixed without due care, or upon considerations which do not apply to the actual behavior of fibres under joint stress, there is obvious danger of giving it too low a value. Whether such unduly low value would be liable to overtax the steel depends upon the limiting stress on the concrete. In the proposed London County Council regulations this is reduced so drastically that even if a modular ratio of 15 actually obtained in place of 11 or 8, as stipulated, the permissible stress on the steel would still be greater than m times the greatest permissible stress on the concrete. But the London County Council concrete stresses on columns are only one-half to one-third of those recommended in the Royal Institute of British Architects' report, which was drawn up by well-known men selected to represent great institutions. As the Committee's report attached to the London County Council's code carefully throws upon the Local Government Board the responsibility of these reductions, it is scarcely probable that in any case outside the small legal scope of the new code engineers and designers will discard the considered recommendations of the Royal Institute of British Architects' Committee until they know how the new stresses were arrived at. The suggestion that the modular ratio should be reduced for richer, stronger concretes is not a new one and will probably find many adherents. But if this be done, it must be recollected that it is equivalent to relieving the steel of part of its responsibility. For instance, if a prudent designer, using the Royal Institute of British Architects' stresses on 1:1½:3 concrete for a

1:1:2 Concrete, $c = 650$, $m = 8$.



column 100 sq. in. area, with 3 per cent. of vertical reinforcement, adopted a ratio of 11 instead of 15, he could load his concrete up to 1,456 lb. per sq. in. (or 0.52 U) under which conditions his speed would be stressed to $m\ c$, or 16,016 lb., if $m = 11$. The equivalent section would be $100 + \{3 \times (m - 1)\} = 130$ sq. in., and the permissible load would be $130 \times 1{,}456 = 189{,}280$ lb., or, say, 84 tons. But if at working stresses the proper value of m were really 15, then the equivalent area would be $100 + \{3 \times (m - 1)\} = 142$ sq. in., and the stress on the steel would be $\frac{189{,}280}{142} \times 15$, or 20,000 lb. per sq. in., instead of 16,000.

The correct practical value to be attributed to the modular ratio is therefore at least worthy of exact and authoritative determination, not only in justice to the capabilities of the material, but also on the score of safety.

PROPOSED CANADIAN INSTITUTION OF MUNICIPAL ENGINEERS.

The following gentlemen have consented to act on the provisional committee appointed to draft out the constitution and arrange the preliminaries of the proposed Canadian Institution of Municipal Engineers: Mr. J. Antonisen, street railway superintendent, Brandon, Man.; Mr. M. H. Baker, city engineer, Prince Albert; Mr. Willis Chipman, consulting engineer, Toronto; Mr. G. T. Clark, city engineer, Saskatoon; Mr. G. W. Craig, city engineer, Calgary; Mr. Arch. Currie, city engineer, Ottawa; Mr. F. L. Fellowes, supervising city engineer, Vancouver; Mr. G. D. Mackie, town engineer, Swift Current; Mr. T. Aird Murray, consulting engineer, Toronto; Mr. F. McArthur, city engineer, Regina; Mr. H. H. Phillips, city hall, Toronto; Mr. R. Potter, town engineer, Battleford; Mr. J. B. Sterling, city engineer, North Battleford; Mr. L. A. Thornton, city works commissioner, Regina; Mr. R. O. Wynne-Roberts (convenor), consulting engineer, Regina.

A NEW RAILWAY DITCHING MACHINE.

An excavating machine adapted to railway ditching has been patented by Naylor Johnson, Montreal. The machine consists of a framework mounted on skids, having at one end a mast and at the other end a steam winch. The excavator is arranged to draw itself and a train of flat cars.

The point of greatest interest is the arrangement of the single hoisting rope which is rove through blocks on the boom and buckets bail to make a tackle, and then passes over the mast to the winch. When the rope is wound up, the bucket is first drawn up to the boom, and the boom and bucket are then drawn up together to dumping position. In order to return the bucket to cutting position before the boom drops, a check rope is provided for the boom passing over a brake-controlled drum. By tightening the brake as the hoisting rope is slackened off, the check rope holds the elevator boom while the bucket drops to cutting position. The brake is then released to let the check rope slacken with the hoisting rope, so that the boom lowers the bucket into the cut. The boom is arranged to swing through a considerable angle to the line of excavation, and the swing of the bucket is radially adjustable with respect to the boom, so that it will always swing parallel with the car carrying the machine. An adjustable, inclined rail controls the lateral movement of the boom.

There is also an independent boom with a plough attached to it. The plough is arranged to give batter to the ground outside the ditch, this batter being formed to the angle of forty-five degrees. The plough is provided with a rooter point and is also intended for use in levelling rough ground before ditching. The bucket can be detached in a few minutes by withdrawing one pin and cotter. There are many other uses to which it can be put when not in use as a ditcher. Mr. Johnson claims for this machine great simplicity and large capacity combined with great ease and flexibility of operation.

BOOK REVIEWS.

Steam Power Plant Engineering.—By G. F. Gebhardt, Professor of Mechanical Engineering, Armour Institute of Technology, Chicago. Published by John Wiley & Sons, New York. Agents for Canada, Renouf Publishing Company, Montreal. 990 pages; 606 illustrations, besides charts and tables; cloth; 6 x 9 inches. Price, $4.00.

Reviewed by George Service, Wh.Sc.

In his preface to the fourth edition Mr. Gebhardt says: "Although primarily intended as a text-book for engineering students, it is hoped that the new edition will be of interest to practising engineers," and a study of the book convinces one that both the claim made, and the hope expressed, are justifiable.

The author has gathered together from many sources, and arranged in logical order, a large amount of up-to-date practice and discussion covering the subject, and, while the text is sufficiently full for ordinary purposes, the value of the book, especially to practising engineers, is greatly augmented by the extensive bibliography incorporated with the text, forming a splendid reference index for anyone wishing to make independent investigations. The book is remarkably free from "faddishness," such as some novel (and unusual) system of notation, or of nomenclature; and, indeed, the author has taken special pains, by the use of italics, to bring the generally accepted terms to the notice of the student.

In addition to dealing very fully with successful practice, attention is called to various parts of the subject, which, so far, have not been developed to be commercially successful, probably with the object of stimulating investigation along these lines; as, for example, the use of powdered coal. The advantages of such material are very clearly stated, as well as the practical difficulties which have been met with in the attempts to use it.

It has obviously been the intention of the author to deal chiefly with the various details constituting a steam power plant, and very little space has been devoted to the discussion of complete plants, only two central station plants, and one isolated power plant, in Chicago, being described. But one cannot help feeling that the volume would have been more complete had it included, even if only in table form, particulars of a number of typical power stations, which data would probably show that certain fixed proportions existed between the various departments of the plant, and would be of use for practising engineers in making preliminary lay-outs, as well as for advanced students.

The chapter on fuels and combustion contains data drawn largely from United States Government reports, and, unfortunately no reference is made to Canadian coals. The desirability of classifying coals according to the carbon-hydrogen ratio, as adopted by the United States Geological Survey, is pointed out, as it appears to apply satisfactorily to all grades of coal. The subject of combustion in general is treated fully and well, and considerable attention is paid to the use of oil fuel, a number of tests of an oil-burning boiler showing an efficiency of 75.8 per cent. to 83.3 per cent. being given.

Subject matter on the Reciprocating Steam Engine covers over 80 pages, dealing with theory, description of types, and the latest performances obtained, the lowest steam consumption recorded to date being given as 6.95 pounds per indicated horse-power hour. The author points out the advisability of giving the performance in heat units instead of pounds of steam, now that superheated steam is being used.

Steam turbines have become important competitors of the reciprocating engine, and are given very full treatment, taking up about 80 pages. The principal types are illustrated, and the mathematical theory worked out. The advantages of a steam turbine plant are stated thus: "(1) Simplicity; (2) Economy of space and foundation; (3) Absence of oil in condensed steam; (4) Freedom from vibration; (5) Uniform angular velocity; and (6) High efficiencies for large variations in load;" and may be taken as an example of the clear and concise style the author uses throughout the whole book. Each item is afterwards discussed at considerable length. A number of recent performances are given, the B.T.U. per electrical horse-power being as low as 204 for a 2,000 K.W. machine. Comparative costs of the installation and operation of steam turbine and engine plants are given, the balance being in favor of the steam turbine plants.

The high vacuum necessary for recent turbine practice has necessitated considerable modification in the design of the condensing plant, and this part of the subject is treated very fully in the excellent chapters on Condensers and Cooling Towers, and Pumps; and in line with the plan adopted throughout the book, recent data as to the power required, and costs, are given.

One of the most interesting chapters, and one not usually inserted in a technical work of this kind, deals with finance and economics, and the cost of power. At the outset the author points out the necessity for a clear understanding of such much-used (often loosely) terms as "load factor," "curve load factor," "rated capacity," and so on; and gives

definitions of their generally accepted meanings. The cost of each section of the plant is taken up in detail, and a large amount of data given from actual practice, which should be of use to the practising engineer in particular.

All the other chapters, including a very good one on Superheated Steam and Superheaters, are well written and illustrated, but do not call for any special remarks.

In printing the tables an occasional decimal point has been misplaced, and in one place the author states that turbine plants of over 60,000 K.W. capacity can be installed for $65.00 per K.W., while in another he gives the cost as $75.00. Occasionally he touches on debatable ground, as, for instance, when discussing the use of kerosene in boilers he says: "Kerosene oil and other refined petroleum oils are sometimes used with good effect in boilers to prevent scale from adhering;" while later on he adds: "Evidently oil does not have the same effect or give the desired result in all cases." But as a rule his conclusions are extremely definite.

Throughout the book are many diagrams plotted from actual results, which are useful in themselves, and also as illustrating the graphical method of making records and compiling data. The author recommends the use of the "Mollier Total Heat Entropy Diagram" in place of the usual steam tables, and a copy of this diagram is given in the appendix.

Although the volume consists of nearly 1,000 pages, it is extremely concise in its treatment throughout, excessive elaboration being entirely absent; and after a careful study one is satisfied that it is well worthy of a place in any technical library, be it that of a student or practising engineer.

Hydraulic Turbines, with a Chapter on Centrifugal Pumps. —By R. L. Daugherty, Assistant Professor in Sibley College, Cornell University. Published by McGraw-Hill Book Company, New York. Cloth; 6 x 9¼ inches; 156 pages; 96 illustrations. Price, $2.00.

Reviewed by T. H. Hogg,
Assistant Hydraulic Engineer, Hydro-Electric Power Commission of Ontario.

This little volume is a most timely addition to the literature on hydraulic turbines. While a number of treatises have appeared at different times dealing with the design of turbines, these have dealt with the subject in such a manner that they have been of little use to the busy engineer who desires to make a proper choice of wheel under given conditions. Comparatively few men are interested in the design of hydraulic turbines, for a relatively small number are called upon to design machines. The design of water turbines is a highly specialized industry, requiring considerable empirical knowledge, which can be learned only through experience. On the other hand, with the great increase in the number of power developments, a vastly increasing number of engineers are finding it necessary to familiarize themselves with the construction of turbines and to understand their characteristics, in order that they may be able to make an intelligent selection of a type and size of machine for any given set of conditions. This book will appeal to this latter class, for it presents in short, concise form the conditions that bear on the choice of turbines. The general question of the development of water-power is dealt with only in so far as it bears on the choice of turbines.

The author states that his purpose in proposing the text was to give a general idea of water-power development and conditions affecting the turbine operation, a knowledge of the principal features of construction of modern turbines, an outline of the theory and the characteristics of the principal types, commercial constants, means of selection of type and size of turbine, cost of turbines and water-power, and comparison with cost of steam power. A chapter is also included on centrifugal pumps, covering the essential points an engineer desires to know to aid him in the selection of a proper type of pump.

The book should appeal to all engineers interested in the subject of hydraulic turbine selection.

Toothed Gearing.—By Geo. T. White, B.Sc. (London). Published by Scott, Greenwood & Son. 210 pages; 4½ x 7 inches; 136 illustrations and diagrams, also tables. Price, $1.00 net.

Reviewed by Chester B. Hamilton, Jun., B.A.Sc.,
Manager, Hamilton Gear and Machine Company, Toronto.

This is a treatise on Toothed Gearing, as distinguished from Gear Cutting, or practical applications of gears. These latter subjects are excluded and reserved for separate treatment. In this there is no doubt that the author is wise, as the subject in hand is amply large for the size of the book.

The work is modern, being dated July, 1912. Some of the data is new, having been previously published only in the Proceedings of technical societies. Most of the material is old and standard, but is compiled and presented in an effective and clean-cut manner.

The work leans toward the theoretical, rather than the practical, but this cannot be avoided. It is a suitable presentment of the theory for the use of the practical gear-man, as well as for one interested in the theory for itself. That is far more than can be said of most books handling such subjects.

Below is the list of chapter headings: I.—Kinematics. II.—The Spur Wheel, Cycloidal Teeth. III.—Annular Wheels, Cycloidal Teeth. IV.—The Spur Wheel, Involute Teeth. V.—Obliquity of Action. VI.—Pin Gearing. VII.—Non-Circular Wheels. VIII.—Lobed Wheels. IX.—Helical Wheels. X.—Bevel Wheels. XI.—Skew Bevel Wheels. XII.—Worm Bearing. XIII.—Oblique Worm and Wheel. XIV.—Screw Wheels or Spiral Wheels. XV.—Strength of Teeth. XVI.—Durability. XVII.—Trains of Wheels. XVIII.—The Odontograph.

The whole field is quite well covered, and, taken all around, it is a book to be recommended for anyone having a serious interest in gears.

Diagrams for the Solution of the Kutter and Bazin Formulæ. —Prepared by Karl R. Kennison, M. Me. Soc. C.E., Providence, R.I. Published by the author. Two diagrams and explanatory notes. 4 pages; size, 9 x 11 inches. Price, $1.00, postpaid.

Reviewed by J. J. Traill, B.A.Sc.,
Lecturer in Hydraulics, University of Toronto.

These diagrams are so arranged that when any three of the four variables, Slope, Hydraulic Radius, Roughness Factor, and Velocity, are known, the fourth may be scaled. There are two very decided advantages over most graphical representations of the Kutter and Bazin Formulæ, namely, the facts that the desired quantity may be scaled without a straightedge, and that the fourth variable plotted is the velocity and not the Chezy Coefficient. The author makes the claim that the results obtained are as accurate as the uncertainties in the application of the formulæ warrant. A careful examination indicates that this is true for the great majority of cases, the exceptions being for materials so uniform in surface that the value of the roughness factor is well fixed. A weak point in the diagram of Kutter's Formula is the omission of a number of the lines of roughness that might readily have been plotted, and, if inserted, would add greatly to the ease with which the diagram could be used. The diagrams are, however, extremely simple to use, both on account of convenient size and good arrangement.

Laboratory Manual of Testing Materials.—By William Kendrick, Hatt, C.E., Ph.D., Professor of Civil Engineering, Purdue University; and H. H. Scofield, M.E., Assistant Professor in Laboratory for Testing Materials, Purdue University. Published by McGraw-Hill Book Company, Inc., 239 West 39th Street, New York. Cloth; 5 x 7½ inches; 125 pages. Price, $1.25 net.

Reviewed by Robert J. Marshall, B.A.Sc.,
Department of Applied Mechanics, University of Toronto

In the mass of engineering literature published on all sorts of technical subjects, this book by Professors Hatt and Scofield is the first work of its kind which has come to my notice on this particular subject. There is a real field for a student's text in Testing Materials, and this book is the first of its kind which deals in detail with experiments and methods of performing the tests, and seems to fulfil the above need.

The book, which is of convenient size, is well edited and nicely bound. It is divided into two sections. The first forty pages contain: a chapter on general instructions to the student, such as the necessary precautions for successful experimenting; a chapter of definitions which serves to refresh the instruction of the earlier years and a chapter descriptive of the ordinary machines and instruments used in an average experimental laboratory. Chapters VI. and VII., which comprise the second section, outline the experiments and give detail methods of performiug each experiment. The instruction is precise and to the point. The references are well chosen, and in all the book appears to be the result of long experience in this kind of work.

Reinforced Concrete Construction.—By M. T. Cantell, Head of the Technical Department of the Kelvin Technical High School, Winnipeg, Man. Published by E. F. & N. Spon, London, Eng., and Spon & Chamberlain, 123 Liberty Street, New York. 240 pages; 250 illustrations; 7 plates; 7 x 10 inches. Price, $5.00 net.

Reviewed by Prof. P. Gillespie
Department of Applied Mechanics, University of Toronto.

This well-printed volume, comprising some 240 pages, is the second and more advanced of two works by Mr. Cantell on reinforced concrete design. A knowledge of the elements of design in this material is really necessary to an understanding of the text, and it is assumed by the author that the reader possesses such a knowledge. The book favors the British in its notation, in its illustrative typical designs, and in the authorities which it follows. This is apparent, for example, in those somewhat arbitrary rules of design which all regulations contain, and which are necessary in cases where theoretical treatment is impossible or unduly involved. Such matters as the limiting ratio of width of slab to thickness of web in tee-beams, and the minimum spacing of rings in columns reinforced by hoops are decided according to R.I.B.A. practice rather than American. This circumstance, however, should not spoil the text for American readers nor deprive them of its benefits. Indeed, it is the reviewer's opinion that had American practice been leavened somewhat more by British caution and thoroughness during the past decade, fewer fatal failures of reinforced concrete structures on this continent would have occurred.

An excellent feature of the work is the large number of actual problems which have been worked out in detail by the author. These comprise a great many types of construction in reinforced concrete, and are admirably adapted to the needs of the inexperienced designer. Graphical and analytical methods are employed, and the problems present great diversity.

The chapters on Retaining Walls, Water Tanks and Towers, Bunkers, and Arches and Bridges are among the most interesting in the book, and, as the reader will observe, investigate fields among the latest of those invaded by this material, whose applications in building construction are daily increasing in number. The volume is a marked improvement over the ill-digested amateurish stuff that, during recent years, has appeared on this side of the water, and could very properly find a place in the library of both young and old students of the subject.

Locomotive Boiler Construction.—By Frank B. Kleinhan, with additions by George L. Fowler, M.E. Published by Norman W. Henley Publishing Company, 132 Nassau Street, New York. 478 pages; 5 folding plates; 40 tables; 350 illustrations; cloth; 5½ x 8 inches. Price, $3.00 net.

Reviewed by R. W. Angus,
Professor of Mechanical Engineering, University of Toronto.

This is a practical treatise for the use of boiler-makers, boiler-users and inspectors; and, since it is designed for the practical man, there is none of the so-called theory, to speak of, in its subject matter.

The chapter on the types of boilers is very short, and is purely introductory, no illustrations being inserted. The laying out of the various sheets of a boiler, which is next dealt with, is a quite complicated and difficult matter, requiring much skill for exactness. The author has omitted the elaborate methods, substituting for them approximations which are probably accurate enough. Explanations as to why things are done are usually not given, and for this reason the reader might have trouble applying any of the methods to slightly different designs.

Considerable space has also been devoted to flanging, which has been treated entirely in a descriptive way, and illustrated quite fully. This is followed by chapters on punching, shearing, plate-planing, etc., the effort being to follow the various parts through the shop in order in which the work would be done. Riveting and staying receive some fair share of attention, and such matters as the mountings and general assembling are dealt with.

The concluding 120 pages contain tables of various sorts, many of which would be helpful, while the back of the book contains five folding plates.

To the builder or mechanic wanting general ideas on working out the details of a locomotive boiler the book would be of some interest, but as it deals only with the locomotive boiler it can scarcely be said to be of general interest. The problems connected with the building of the locomotive boiler are, however, similar to those with other types.

PUBLICATIONS RECEIVED.

Office and Field.—Seventh annual convention number of the L.U.A.C., Ottawa, 1913. 372 pages, 6½ x 10 inches. Published by W. B. Campbell.

Carbon Circuit Breakers.—Circular No. 1205, of the Canadian Westinghouse Company, Limited, Hamilton, Ont., is descriptive of a half-dozen types, and their auxiliary mechanisms.

Handbook of British Columbia.—Bulletin No. 23 (seventh edition) of the Bureau of Provincial Information, descriptive of British Columbia, as to its position, resources, climate, industries, etc.

The Resources of Tennessee.—This is a magazine published quarterly by the State Geological Survey, and devoted to the description, conservation, and development of the resources of Tennessee.

The Inflammability of Coal Dust.—Bulletin 50, of the United States Bureau of Mines, comprises the results of laboratory experiments by Messrs. J. C. W. Frazer, E. J. Hoffman, and L. A. Scholl, Jr.

Report of Nelson P. Lewis, Chief Engineer of the Board of Estimates and Apportionment of the City of New York for the year 1912. It is a volume of 300 pages, including 37 tables, together with various maps, etc.

Hamilton.—A 340-page book, published by Herbert Lister, Hamilton, Ont., descriptive of the city, its history, commerce, industries, and resources, and published in connection with the Centennial Industrial Exhibition held recently.

The Geology of the Cowganda Mining Division.—Memoir No. 33 of the Geologic Survey Branch, Department of Mines, Ottawa. It is a 120-page book, supplemented with maps and photographs covering the general and economic geology of the district.

Society of Railway Club Secretaries.—A 24-page booklet, indexing the papers and subjects discussed by railway clubs during the year ending May 31st, 1913. The secretary of the Society is Harry D. Vought, New York and Central Railway Club, New York City.

The Theory of Loads on Pipes in Ditches, and Tests of Cement and Clay-Drained Tile and Sewer Pipe.—Bulletin No. 31, Engineering Experiment Station, Iowa State College of Agriculture and Mechanic Arts. The authors are A. Marston and A. O. Anderson.

Mineral Production of Canada.—Bulletin No. 238, Mines Branch, Department of Mines, Ottawa, contains a general summary of the mineral production of Canada, 1912, compiled by John McLeish, B.A., Chief of the Division of Mineral Resources and Statistics.

The Textile Industry and the Tariff.—An address by A. F. Greene, delivered to the National Association of Cotton Manufacturers by Mr. Greene, retiring president. Published in booklet form by Lockwood, Greene Company, architects and engineers for industrial plants, Boston and Montreal.

Le District D'Ungava, Le Nouveau Quebec.—231 pages, 7½ x 10½ inches, illustrated, with map appended. Extracts from reports on the district of Ungava, recently annexed to the Province of Quebec. Published by the Bureaus of Mines and Fisheries, under the authority of the Minister, the Hon. C. R. Devlin.

Report on the Health of the City of Manchester, 1912.—203 pages, 6 x 10 inches, dealing with notified infectious diseases, and the work done to combat these under the various branches of the department of health. Issued by James Niven, M.A., M.B., LL.D., under the authority of the Department.

Commerce and Finance of the United States.—105 pages, 10 x 12 inches. Monthly summary of the foreign commerce of the United States, and of tables of commercial finance for July, 1913. Issued by the United States Bureau of Foreign and Domestic Commerce. A. H. Baldwin, Chief of Bureau, and O. P. Austin, Assistant Chief.

Oil and Gas Prospects of the North-west Provinces.—99 pages, 7 x 9 inches, with illustrations and map. Discusses the character of the district, and its general and economic geology. Published by Wyatt Malcolm, and by authority of the Hon. Robert Rogers, Minister of the Dominion Government Department of Mines.

Analyses of Coal.—Bulletin No. 22 of the Bureau of Mines, Department of the Interior, Washington, D.C. It is published in two volumes, Part I. of 320 pages, dealing with the analyses of coals in the United States, collected over a period of six years; and Part II., of 1,200 pages, dealing with descriptions of the various samples.

Forest Products of Canada—Poles and Cross-Ties.—A 16-page pamphlet published by the Forestry Branch, Department of the Interior, as Bulletin 30, containing statistics, compiled by R. G. Lewis, B.Sc.F., based upon reports from 389 companies, representing 95 per cent. of the wooden-pole users in Canada, concerning their purchases for 1912.

The Titaniferous Iron Ores in the United States.—First edition, June, 1913. Illustrated, 145 pages, 6 x 9 inches. Discusses the chemical composition of titaniferous iron ores, the economic importance of the deposits, and their character, situation, and possibilities. Published by Joseph T. Singewald, Jr., by authority of the United States Government Bureau of Mines.

Oil and Gas Prospects of the North-West Provinces of Canada.—Memoir No. 29E of the Geological Survey of Canada. Compiled by Wyatt Malcolm, and containing full information concerning the geological formations in that portion of the Dominion, comprising practically all of the Provinces of Manitoba, Saskatchewan and Alberta. The report occupies 100 pages, and is supplemented by tables and maps.

Report, Minister of Lands, Forest and Mines, Ontario—This report for the year ending October 31st, 1912, deals with the management, etc., of the Crown Lands of the Province of Ontario. It includes returns, statements of sales, of revenues, receipts and disbursements, timber dues, municipal surveys, Crown surveys, etc., etc. Several appendices are devoted to the construction of roads in Northern Ontario, and Mr. J. F. Whitson's report is included.

Wood-using Industries of Ontario. Bulletin No. 36, Forestry Branch, Department of the Interior, Ottawa. It is compiled by R. G. Lewis, B.Sc.F., and contains an account of the quantity, value and source of supply of the different kinds of wood used by the industries of Ontario. It includes detailed descriptions of the different classes of industries, and the properties of the woods used. A classified directory of manufacturers is appended.

Long Sault Rapids, St. Lawrence River.—By Arthur G. White, M.E., Engineer to the Commission of Conservation, Canada. This is an engineering report upon the rapids, containing an inquiry into the constitutionality of the Long Sault Development Company's charter, and into the effect on navigation, and the general advantages or disadvantages accruing to the people of Canada from the project to develop electric power from these rapids. The volume comprises 384 pages. It is accompanied by about 25 illustrations and maps. This is the Commission's report upon a question which was dealt with editorially in Sept. 4th issue of this journal.

Precise Levelling is the title of a publication of the Dominion Observatory, Ottawa; W. F. King, C.M.G., LL.D., Director. Mr. F. B. Reid, D.L.S., is the author. The report deals with the results of precise levelling done by the Geodetic Survey as far as they are ready for publication at the present time. Table I. outlines the routes followed between terminal points, and describes all bench-marks established. Table II. gives the distances between bench-marks; the difference between forward and backward levelling for each section between bench-marks; the elevations of the bench-marks; and the elevation also of bench-marks established by other surveys and connected with Geodetic Survey work. Table III. gives the elevations at railway stations along different lines of levels. The publication is supplemented by several maps descriptive of the routes.

American Society for Testing Materials, Index to Proceedings, Vols. I.-XII.—158 pages, 6½ x 9 inches. An index of the contents of Vols. I.-XII. of the proceedings of the American Society for Testing Materials, excluding only portions which relate to routine business. From 1898 to 1902, the society issued 28 bulletins, and these have been compiled as Vol. I. From 1902 to 1913, the association has issued a report of its proceedings annually, and these successive reports have been published separately in Vols. II.-XII.

Completing the Index is a Table of Contents of Proceedings, which gives the contents of the final eleven individual volumes. In this volume the titles of papers have been distinguished by quotation marks, and committee reports and specifications have been indexed under subjects appropriate to their titles. Prefixed to the Index is a list of key-words under which these subjects have been indexed; and the Index itself is classified under subjects and authors. The publication is issued by the society at the University of Pennsylvania, Philadelphia, Pa.

The Cobalt-Nickel Arsenides and Silver Deposits of Temiskaming, Report of the Bureau of Mines (Fourth Edition).—279 pages, 7 x 10 inches, fully illustrated and well supplied with inset maps. The book is divided into three chapters and four appendices. Chapter I. contains 132 pages, and deals with the district of Cobalt proper, the character and origin of its veins, ores and minerals. Chapter II. considers for 63 pages the Outlying Cobalt Areas, and a like discussion of their mineral products. Chapter III. gives in 30 pages an analysis of Lake Superior silver deposits, other Canadian Nickel-Cobalt ores, and foreign Cobalt deposits. The four appendices discuss respectively the Paleozoic Rocks of Lake Temiskaming, a profile from Toronto to Hudson Bay slope, the early history of the Cobalt industry in Saxony, and mining and concentrating methods at Cobalt. In this edition little is added to the economic geological description given in former editions; but some features have been treated more fully, such as underground work in the mines, which has furnished many details concerning the structural relations and the character of the veins.

Twentieth Annual Report of the Massachusetts Highway Commission, 1912.—333 pages, 6 x 9 inches, with map appended, containing Parts I. and II; the former dealing with State highways and motor vehicles; the latter, with the supervision of telephone and telegraph companies. Part I. comprises in 200 pages the report of the Massachusetts Highway Commission, consisting of Wm. D. Shier, chairman F. D. Kemp, and J. W. Synan; the report of Chief Engineer A. W. Dean, as Appendix A; and twelve additional appendices. A thorough discussion of the department's work upon State roads and in the supervision of automobiles marks the first portion of Part I. as most valuable, though the traffic census is also discussed at length, and constitutes a special phase of the book, which is elaborated in Appendix L by 28 pages of traffic records. Part II. consists of the annual report of the Massachusetts Highway Commission concerning companies engaged in the transmission of intelligence by electricity, which is supplemented by three appendices. There are three half-tone illustrations, two showing improved roads, and the third is of a 42-foot span reinforced concrete bridge. The appendaged map shows in tones of red the roads petitioned for, roads laid out, and town roads improved in Massachusetts. Wright & Potter Printing Company, Boston, Mass.

CATALOGUES RECEIVED.

Fractional Horse-Power Motors and Applications.—Illustrated leaflet, showing the various forms of fractional horsepower motors offered by the Canadian General Electric Company, Toronto.

Universal Bulletin.—Illustrated monthly, showing use of Portland cement in concrete bridges and buildings of various kinds. Published by the Universal Portland Cement Company, of Chicago, Ill.

A Thousand Uses for Gas.—The September number of an illustrated periodical issued to manufacturers by the Industrial Division of the United Gas Improvement Company, Philadelphia, Pa.

Efficient Roundhouse Lighting is the subject of a small pamphlet published by the Canadian General Electric Company, Limited, Toronto, and dealing with a type of reflector for use in roundhouses.

Incineration.—A neat 22-page pamphlet descriptive of some of the plants of the Decarie incinerator for the disposal of garbage and refuse. Published by the Decarie Incinerator Company, Minneapolis, Minn.

Steam-Driven Compressors.—A 12-page catalogue is published by the Canadian Pneumatic Tool Company, descriptive of Class "M" Chicago Pneumatic Corliss type compressor. It is Bulletin No. 24-T.

Country Sewage Purification.—Tuke & Bell, Limited, Sewage Specialists, London, E.C., describe their semi-septic system of sewage purification which they install for cottages, country houses, institutions, etc.

Condulets.—New types for railway requirements are listed and illustrated in Bulletin 101 of the Crouse-Hinds Company of Canada, Limited, of which Canadian General Electric Company are the selling agents.

Annual Report of the Quebec Railway, Light, Heat and Power Company, Limited.—An illustrated pamphlet, including maps, giving the report for the fiscal year ending June 30th, 1913, adopted by the company at its third annual meeting.

Mesta Gas Engines.—The Mesta Machine Company, Pittsburg, Pa., have issued a bulletin descriptive of their gas engines, which they build for any gas fuel—producer, blast furnace, coke oven, or natural, and in sizes from 350 B.H.P. upwards.

Catalogue "C" of the DeLaval Steam Turbine Company describes class "C" velocity-stage type. It is a catalogue of 108 pages, well illustrated and full of interesting data. The Turbine Equipment Company, Limited, Toronto, look after the sale in Canada.

Smut Diseases of Cultivated Plants.—Illustrated bulletin, giving a description of the different varieties, their history and treatment. Issued by H. T. Güsson, Dominion Botanist, and published by direction of Hon. Martin Burrell, Minister of Agriculture, Ottawa.

Illumination of Construction Work.—This is an illustrated description of the G. E. Type "W" flame arc lamp, and of its suitability for use by the modern contractor on his night-work jobs. The Canadian General Electric Company, Toronto, are selling agents.

Hand-Drills and Portable Compressors.—Illustrated pamphlet dealing with the Chicago Valveless Hand-Drill and the "Chicago Pneumatic" Portable Gasoline Engine-Driven Air-Compressor. Published by Chicago Pneumatic Tool Company, of Chicago and New York.

Wizard Rock Drills.—This product of the McKiernan-Terry Drill Company, New York, is described in a 12-page illustrated booklet. Prices and specifications of the various types and of their duplicate parts are given. Canadian Allis-Chalmers, Limited, Toronto, are agents.

Coal-Mine Fatalities in the United States.—A catalogue of tables, giving statistics of July coal-mine fatalities, and revised figures for preceding months. Compiled by Albert H. Fay, and published under the direction of the Bureau of Mines, United States Government, Washington, D.C.

Multi-Stage Type DeLaval Steam Turbines.—Described in Catalogue "D." The book is a 120-page description of the field, design, construction, and adaptation of the multi-stage DeLaval Turbine. A section of the catalogue is devoted to the company's double-helical speed-reduction gear. The catalogue is educative in the information which it contains, and shows, among other important details, the use of the DeLaval diagram and steam scale for determining the consumption of an engine or turbine under given steam conditions.

COAST TO COAST.

Regina, Sask.—To encourage the growth of smaller industrial companies, a movement has been begun in Regina to secure cheaper power for concerns using from 50 horsepower up. This means that the city council will be requested to grant the minimum rate to users of 50 horsepower or over instead of 100 horsepower as at present.

Ottawa, Ont.—The civic waterworks committee has appointed a sub-committee to investigate the meter system on water services as in vogue in some cities. This action has been taken merely to gain information concerning a method that might show how much water each place is consuming, so that the water rates might be based on the quantity of water consumed.

Fort William, Ont.—Actual work is now in progress on the extension of the Empire Avenue street-car line across the new C.P.R. bascule bridge to island number two. The work on the island has been proceeding for some time, and before the frost sets in, it is expected that all the rails will be laid from the bridge approach along Sixth Avenue to Eighth Avenue, and from thence down to the Mission River.

Hamilton, Ont.—Engineer Sifton, of the Hydro-Electric Department, has submitted statements to the board of control showing that the gross profits from the department for the past eight months have been over $26,000, the net almost $6,000. He furnished in addition an estimate of the amount required to complete the system so as to provide for the increased demands, showing an expenditure of $335,264, according to one plan, and $320,330, according to an alternative plan. For the larger amount, he informed the board that he would be in a position to supply eight times the number of customers that could be accommodated by the original system; and that cost about $500,000.

Fredericton, N.B.—The repairs and improvement being undertaken on the Fredericton-St. Mary's highway bridge are progressing satisfactorily both as far as efficiency and economy are concerned. The original estimate of cost was between $45,000 and $50,000; and President Remington, of the Foundations Company, Limited, the contracting company for the work, has stated after carefully inspecting the work and accounts thus far, that the estimate will not be exceeded, but rather that with favorable conditions, the work will be completed at less than the estimate, and will be a permanent piece of construction with which the best experts in America will be unable to find fault.

Ottawa, Ont.—Mr. L. G. Denis, expert for the Hydro-Electric Commission, has taken a thousand-mile trip through the northern Manitoba and Hudson Bay districts, and has given a report of his survey of important water powers, which disburses the possibility of the operation of the Hudson Bay Railway by hydro-electric power, an idea which has at times been promulgated. He states that though there are many water powers, economic conditions for development are not probable; since a continuous market for the power, for which there is little prospect, would be necessary to insure profit. The economic potentialities of the territory are such that any saving which might be effected by the operation of the road would hardly repay the cost of development.

Vancouver, B.C.—Mr. O. B. Dickeson, president of the White Pass and Yukon route, who has spent the greater part of the summer in the north, upon arriving in Vancouver, confirmed previous statements sent from Dawson City that his company will undertake important extensions to the transportation system in the North, and will also make every effort to provide for the present activity along the trails into the Shushanna country and the scene of the recent gold strike. The company's extensions into the White River district will be carried out, provided the development continues and it is possible to secure Governmental assistance. This he did not doubt, since the company's mining engineer had examined the territory, and had reported that, if transportation could be offered, the future of the White River country copper deposits was very promising.

Victoria, B.C.—Mr. Chambers, of the Irrigation Board of the Department of the Interior, recently visited Victoria, and while there made some interesting statements relating to the irrigation projects being developed in the Northwest provinces. He claimed that thousands of acres of semi-arid lands are being turned into valuable tracts and gave concrete evidence in instances of vastly improved germination that had come under his personal notice, to the greatest extent in the Bow River district. He said concerning the Bow River scheme that it was one of the largest projects of its kind on the continent, that the first two sections are completed, and their contributory lands under tillage, that the third section, which is fed by the Bassano dam, is rapidly nearing completion, and that the water will soon be let into the dam. The first section, which embraces an area of 300,000 square acres, is situated almost entirely south of the Calgary and Medicine Hat line down to the Bow River, and has been an important factor in the agricultural development of a section that was not looked upon very favorably in pre-irrigation days. Although these three units serve an immense area, it is the general opinion in Alberta that the C.P.R. will further develop this scheme and make it eventually one of the largest irrigated areas in the world. The dams are of concrete and splendidly constructed, and it is expected that there will be a big demand for the affected land when it is put on the market. In addition to the C.P.R., the South Alberta Land Company has irrigated large areas in that province. The Irrigation Board is not concerned with the actual work of construction, but it issues licenses for the utilization of the necessary number of cubic feet of water per second required for the development of the project, and all irrigation schemes and the structural details of the dams and ditches are submitted to the engineers of the board for sanction before the work is begun.

PERSONAL.

B. W. SETON, of the Dominion Engineering and Inspection Company, Montreal, has been appointed Toronto manager of his firm in order to handle the inspection work on the new Royal Bank Building, the Central Technical School, etc.

F. B. TAYLEY, resident engineer at London, Ont., for the Canadian Pacific Railway, has been transferred to the Montreal division, and is being succeeded at London by S. S. ROSSITER, of Cranbrook, B.C.

WALTER J. FRANCIS, C.E., consulting engineer, Montreal, read an address to the University of Toronto Engineering Society at the opening meeting for the 1913-14 session. The subject was "Engineering as a Profession."

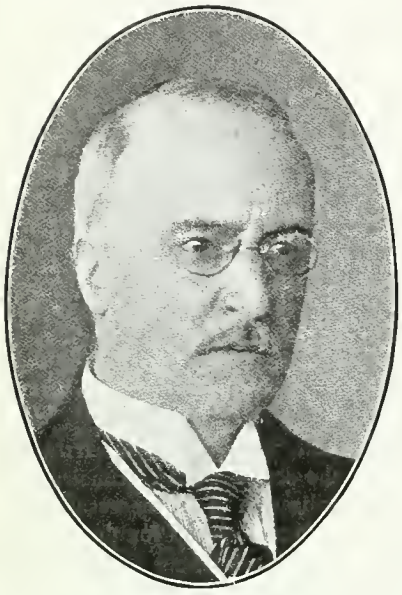
CUNNINGHAM CRAIG, former geological surveyor of Great Britain and of Trinidad and Tobago, consulting geologist to the British Government, is in Alberta at present, conducting a rigid survey of the oil lands to the south-west of Calgary. He has announced, unofficially, that the territory indicates that the possibilities for oil in abundance are tremendous. The Province is receiving wide attention from oil experts at present.

W. S. HARVEY, the new city engineer of Lethbridge, as recently announced in this column, has been connected

with the department of the city engineer for two years as assistant engineer in charge of sewers and waterworks. Previous to his going to Alberta, he spent some time in Toronto, as assistant engineer in the main drainage department. He spent eleven years on engineering work in England—on dock work at Bristol and Hull; on pumping station installation at Somerset; pier and coaling station construction at St. Vincent, Cape Verde Islands; sea defence work at Barry, South Wales; tramway construction at Chesterfield, and jetty work at Newport.

OBITUARY.

DR. RUDOLPH DIESEL, Hon. M. Am. Soc. M. E., of Munich, Germany, famous as an inventor of the Diesel oil engine, while on his way to London to attend the annual meeting of the Consolidated Diesel Engine Manufacturers, mysteriously disappeared from the steamer en route on the evening of September 29th, and, although for some little time hope was entertained of his being alive, it later developed that his disappearance was due to death by falling overboard through some mischance.



Dr. Rudolph Diesel.

Dr. Diesel was born in Paris in March, 1858. After courses of study at Augsberg, he entered Munich Technical College, where he graduated in 1879, specializing in thermodynamics. After spending some years on the staff of the college as assistant to Prof. von Linde he became manager of the French company for the manufacture of the von Linde refrigerating machinery in Paris.

Dr. Diesel's theories regarding prime-movers with higher thermal efficiency than the steam engine attracted world-wide attention in the early nineties, and in 1893 the first Diesel engine made its appearance. This experimental engine was wrecked by explosion at the first injection of fuel. The second Diesel engine, however, confirmed the inventor's theory of initiating combustion by compressed air. The third Diesel engine, built in 1897, and the fourth in the following year, were those that fixed the type upon which all slow-speed stationary Diesel engines have since been built. The progress and development of the engine during the past fifteen years is familiar to readers of this journal, it being now in service in practically every industrial country of the world.

Besides his honorary membership in the Am. Soc. M.E., Dr. Diesel was a member of the managing board of the Verein Deutscher Ingenieure. He was a director of five of the leading companies building Diesel engines in America and Europe.

W. F. DE VOE, connected with one of the British Columbia Government survey parties at Strathcona, lost his life by drowning while crossing Campbell River on October 19th. Mr. De Voe was a native of Los Angeles, Cal.

H. S. WESTBROOK, ex-Mayor of Winnipeg, and a prominent figure in the city's municipal development, died at his home in Winnipeg on October 19th. Mr. Westbrook was the father of President Wesbrook of the University of British Columbia. Another son is a prominent mining and metallurgical engineer in Duluth.

BRIDGE BUILDERS IN MONTREAL.

The American Railway Bridge and Building Association held its twenty-third annual convention last week in the city of Montreal. This is the second occasion of the Association's choice to convene in a Canadian city, Quebec having been previously chosen.

Mr. A. E. Killam, of Moncton, N.B., is president of the Association.

THE CANADIAN SOCIETY OF CIVIL ENGINEERS.

Mr. James Spelman, vice-president of the John S. Metcalf Company, addressed the Montreal meeting of the Canadian Society of Civil Engineers, on October 16th, on the subject of the development of grain elevator construction. Mr. C. N. Monsarrat, chief engineer of the Quebec Bridge Company, was chairman.

At the November 6th meeting in Montreal, an important paper on "Filtration" will be read by Mr. F. F. Longley.

POSTPONED MEETING.

The convention of the Great Lakes International Pure Water Association, to have been held in Toronto, November 6th and 7th, has been postponed until further notice. The Secretary is Paul Hansen, Urbana, Ill.

A NEW CENTRIFUGAL PUMP.

At its meeting on November 11th in New York City the American Society of Mechanical Engineers will hear an address by Mr. C. V. Kerr, on a new centrifugal pump with helical impeller. Mr. Kerr, who is a sales engineer for the A. S. Cameron Steam Pump Works, claims that the reason for seeking a new type of pump is based on the characteristic behavior of the small steam turbine, which is commonly used in power plants, as the driving power for circulating pumps for condensers. The mathematical theory of the new type of impeller will be presented, also an illustrated description of the 8-in. experimental pump used, with methods and results of tests.

COMING MEETINGS.

UNITED STATES GOOD ROADS ASSOCIATION.—Convention will be held at St. Louis, Mo., November 10th to 15th. Secretary, J. A. Rountree, L021 Brown-Marx Building, Birmingham, Ala.

NATIONAL MUNICIPAL LEAGUE.—Annual meeting will be held in Toronto, November 12-15. Secretary, C. R. Woodruff, 705 North American Building, Philadelphia, Pa.

AMERICAN ROAD BUILDERS' ASSOCIATION.—Tenth Annual Convention to be held in First Regiment Armory Building, Philadelphia, Pa., December 9th to 12th. Secretary, E. L. Powers, 150 Nassau Street, New York, N.Y.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS.—The annual meeting will be held in New York, December 2nd to 5th, 1913.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for small fee.

20579—October 7—Authorizing Quebec, Montreal and Southern Ry. Co. to construct siding for Mount Royal Brick Co., Limited, parish of Varennes, Co. Vercheres, Quebec.

20580—October 15—Approving plans Nos. 28 and 31, of city of Toronto, showing viaduct carrying Bloor Street across C.P.R., C.N.R. and G.T.R. Cos., authorized to be constructed under Order No 20437, dated September 23rd, 1913.

20581—October 8—Authorizing C.N.R. to connect its railway with the Manitoba and Saskatchewan Coal Co., Limited, spur in the N.E. ¼ Sec. 19-2-6, W. 2 M., near Bienfait, Sask.

20582—October 15—Approving deviation Lake Erie and Northern Ry. between stations 745.00 and 793.00, Tp. Townsend, Co. Norfolk, Ont.

20583—October 15—Authorizing Lake Erie and Northern Ry. to construct across two highways—namely, Con. Road between Station 771.97.5 to Station 772.60.5; 2. Given Road at Station 613.3.

20584—October 16—Suspending, pending hearing and determination of matter by Board, cancellation as from November 1st, 1913, of inter-warehouse arrangement for completion of carload shipments of grain, notice of which is given by Supplement No. 28 to C.P.R. Tariff C.R.C. No. E.2141, and Supplement No. 18 to G.T.R. Tariff C.R.C. No. E.2374.

20585—October 15—Approving location Lake Erie and Northern Ry. from Station 4.50 to George Avenue, Station 36.60.5, City of Brantford, Ontario.

20586—October 16—Rescinding Order No. 17885, October 29th, 1912, in so far as it authorized crossing of highway between Lots 118 and 119, parish St. Laurent, Co. Jacques Cartier, Quebec.

20587—October 16—Extending, until November 18th 1913, time within which C.P.R. install bell at crossing known as "Miller Crossing," ¾ mile west of Kingsbury, Que. Also extending, until October 30th, 1913, time within which bell at crossing of river road, about three miles east of Kingsbury, between Melbourne and Windsor Mills, Que., be installed.

20588—October 16—Approving plan, filed by C.N.R. and dated Winnipeg, September 10th, 1913, substituted for plans approved under Order No. 20058, authorizing construction of spur across N.E. ¼, Sec. 15, and N.W. ¼, Sec. 14-37-5, W. 3 M., Mun. Cory, Sask., and that Order No. 20058, dated August 11th, 1913, be amended accordingly.

20589—October 15—Authorizing C.P.R. to construct siding for Canadian Wire Co., Limited, situate in part Lot 3607, Emard Ward, Montreal, subject to terms of City's consent to crossing of St. Patrick Street, save and except provision reserving to City right to order Co., to remove said siding upon notice to company.

20590—October 4—Authorizing G.T.R. to reconstruct Bridge No. 202, carrying its railway over Big East River, mileage 150.75, on 12th District, near Huntsville, Ont.

20591—October 16—Authorizing G.T.P. Ry. to construct across and divert highway in Charles Indian Reserve, mileage 317, Prince Rupert East, Coast Dist., B.C., subject to inspection by Department of Public Works for Prov. of B.C.

20592—October 16—Approving location C.N.O.R. station grounds at Isle Jesus, parish Ste. Dorothee, on Lot No. 85, mileage 38.95, Hawkesbury East, Co. Laval, Que

20593—October 17—Authorizing C.P.R. to use and operate over spur of C.N.R. into Government Elevator at Port Arthur, Ont., subject to certain conditions.

20594—October 17—Authorizing C.P.R. to construct, at grade, an extra track allowance between Secs. 27 and 34-21-31, W.P.M., at Langenburg, Sask.

20595—October 17—Authorizing C.P.R. to construct, by means of a grade crossing, tracks of spur to ballast pit across road allowance, situate in N. ½ Sec. 5-7-19, W. 4 M.

20596—October 17—Authorizing C.L.O. and W. Ry. to construct Bridge No. 121.29 across road allowance between Lots 22 and 23, Con. A., Tp. Hamilton.

20597—October 17—Authorizing C.L.O. and W. Ry. to construct across Sinclair Street, Town Cobourg, by means of an undercrossing, at mileage 120.6. And rescinding Order No. 19093, dated April 19th, 1913, in so far as it authorizes crossing of Sinclair Street, at Grade.

20598—October 15—Directing that G.T.P. Ry., within ten days from date of this Order, construct crossing opposite Lot 384 on Queen Street, city of Fort William, Ont.

20599—October 16—Requiring that C.N.R. move loading platform at Bryant Station, Sask., from present location to a point convenient to west end of yard; grade good driveway from road allowance to approach to loading platform; and grade driveway 300 feet long, level with base of rail, at a point just east of proposed location of said loading platform, to be used for team track loading.

20600—October 17—Approving plan and specifications of drain, known as Fleming-Wigle Drain, proposed to be constructed under Windsor, Essex, and Lake Shore Rapid Ry. Co.; Ry. Co., to do work on its own lands.

20601—October 18—Authorizing G.T.R. to construct, temporarily, an additional track across or on road allowance between Cons. 1 and 2, Tp. Brantford, Co. Brant, Ont., subject to conditions that construction of said spur shall not in any manner encroach on travelled portion of said highway, and that highway be kept open and safe for public travel: switch be removed as soon as reasonably possible after machinery is delivered.

20602—October 18—Removing speed restriction of 20 miles an hour over portion of C.P.R. Kerrobert North Easterly Branch from mileage 0 to 25, and 15 miles an hour from mileage 25 to 36.1, Province of Saskatchewan.

20603—October 18—Approving location G.T.R. proposed new station at Seagrave, Tp. Reach, Co. Ontario, Ontario, to replace one recently destroyed by fire.

20604—October 8—Approving C.N.O.R. plan No. D29-1 of subway to be constructed at Wylde Street, town North Bay, Ontario.

20605—October 17—Authorizing G.T.R. to reconstruct Bridge No. 58, at mileage 146.42 from Black Rock, carrying 20th District of its Ry. across Bayfield Creek, at a point 2.11 miles east of Clinton Station, Tp. Tuckersmith, Co. Huron, Ont.

20606—October 18—Approving location Esquimalt and Nanaimo Ry. station at Qualicum Beach, on Comox Extension of its railway, Vancouver Island.

20607—October 18—Authorizing C.P.R. to construct spur for Continental Oil Co., Limited, Winnipeg, Man., from a point on westerly limit of its line in Lot M., plan 252, St. Boniface.

20608—October 17—Removing speed restriction of 15 miles an hour over portion of C.P.R. Wilkie Southeasterly Branch from Wilkie, mileage 0, to Kelfield, mileage 35.3, Sask.

20609—October 15—Approving revised location C.L.O. and W. Ry., Glen Tay to Cobourg Line, as set forth in recital of this Order; and rescinding Order No. 15289, September 22, 1911, approving original location. Authorizing C.L.O. and W. Ry. to take possession of portions of right of way and tracks of C.N.O.R. and authorizing city of Belleville to lay water pipe under C.N.O.R. at foot of Mary Street. Refusing rest of city's application.

20610—October 17—Amending Order No. 20318, dated September 12th, 1913, by striking out figures "20" after word "Range" in 4th line of operative part of Order, and substituting therefor the figure "2."

20611—October 9—Authorizing C.P.R. to install temporary interlocking appliances at crossing of Quebec, Montreal and Southern Ry. at mileage 18.81 from Farnham, Que., until June 30th, 1914.

20612—October 21—Authorizing city of Regina, Sask., to construct its Municipal Street Ry. over Bulyea and Colonsay Branch of C.P.R. at intersection of 4th Avenue, immediately south of Blocks 11 and 12, Eastview, Regina, Sask., subject to certain conditions.

20613—October 17—Authorizing township of Ancaster, Ont., to construct, at its own expense, Broadway Avenue, across T.H. and B. Ry. in West Hamilton, Ont. And dismissing application as to remainder of crossings.

20614—October 17—Authorizing, upon condition that authority granted herein shall be subject, in all respects, to terms of agreement dated December 1st, 1908, between C.P.R. and G.T.P. Ry., G.T.P. Ry., to construct spurs from its main line of railway, across Vickers Street, Fort William, Ont., to its proposed freight yards; and approving location of Co.'s proposed freight station, Fort William, Ont.

20615—October 17—Amending Order No. 19248, dated June 4th, 1913, by adding following words to paragraph 5 of Order: "and paid by the Applicant Company."

20616—October 21—Authorizing Hamilton St. Ry. Co., to operate its cars over crossing of T.H. and B. Ry., at intersection of Main and Trolley Streets, Hamilton, Ont.; interlocking plant be installed on or before November 30th, 1913.

20617—October 18—Authorizing G.T.R. to operate jointly and on equal terms with C.P.R., that Co.'s branch line serving the premises of Canada Foundry Co., Limited, north of Royce Avenue, Toronto, subject to condition that G.T.R. pay to C.P.R. a yearly rental equal to interest of 6 per cent. per annum upon one-half of cost of construction of track, and one-half of cost of maintenance thereof.

20618—October 21—Directing that, within three months from date of this Order, G.T.R. install gates to cover all tracks and sidings as well as main tracks, at crossing of first highway east of Clarkson Station, Ont., to be operated by day and night watchmen: question of apportionment of cost of installing gates be reserved for further consideration by Board. If gates are not erected and in operation within said three months, expense of day and night watchmen employed at crossing will be borne and paid by Ry. Co., until such gates are installed.

20619—October 17—Authorizing G.T.R. to construct siding into premises of Quinlan and Robertson on Lot 10, Con. 9, Tp. Huntingdon, Ont., subject to certain conditions.

20620—October 21—Directing that G.T.R. install, within 90 days from date of this Order, an improved type of automatic electric bell at crossing on Third line, immediately west of Etobicoke River, between lots 5 and 6, Con. 6, south of Dundas Street, Tp. Toronto; 20 per cent. of cost of installing bell be paid out of "The Ry. Grade Crossing Fund," remainder by Ry. Co.

20621—October 18—Directing G.T.R. to construct siding into premises of St. Mary's Portland Cement Co., Limited, being part of Lot No. 22, Con. 17, Tp. Blanchard; and to connect said spur with existing siding and spurs serving Applicant's plant; Applicant to convey to Ry. Co., necessary right of way. All subject to certain conditions. And rescinding Order No. 19365, dated May 21, 1913.

20622—October 21—Authorizing C.P.R. to construct diversion in S.W. ¼ Sec. 6-5-17. W. 4 M., at McNabb, Alta., on its Alberta Div., Coutts Subdivision.

20623—October 21—Extending, until December 15th, 1913, time within which C.P.R. install electric bell at crossing of Main Street, town of Milverton, Ont.

20624—October 22—Relieving C.P.R. from providing further protection at crossing known as Cote du Sud, mileage 11 from Place Viger Station, Montreal, Que.

20625—October 16—Authorizing C.L.O. and W. Ry. (C.P.R.) to construct its tracks, for a period of nine months from date of this Order, over portion of forced road running through Lot 24, Con. 8, Tp. Camden, Co. Lennox and Addington, at mileage 46.3, subject to certain terms and conditions.

20626—October 22—Authorizing T.H. & B. Ry. to open for traffic that portion of new second track from Welland to Welland River, mileage 0.49 to mileage 1.35, Ontario.

20627—October 22—Refusing application T.H. & B. Ry. for an Order declaring it to be senior at crossing of Birch Ave., Hamilton, Ont.; and declaring that city is senior at said crossing of Birch Avenue.

20628—October 22—Authorizing G.T.R. to reconstruct bridge No. 44, 20th Dist., mileage 116.16 from Black Rock, over Wellington St., Stratford, Ontario.

20629—October 22—Authorizing G.T.R. to reconstruct bridge No. 47, 20th Dist., mileage 116.65 from Black Rock, across John Street, city of Stratford, Ont.

20630—October 22—Authorizing C.N.R. and G.T.P. Ry. to operate their trains over crossing at Camrose, Alta., without their being brought to a stop.

20631—October 22—Approving location and details of C.N.R. station at St. Boniface, Manitoba.

20632—October 22—Rescinding Order 20024, dated Aug. 13th, 1913.

20633—October 22—Approving location C.P.R. station at Neptune, on Estevan-Forward Branch, Saskatchewan.

20634—October 21—Authorizing C.P.R. to construct spur for Whitworth Bros., from a point on existing spur in N.W. ¼ Sec. 5-18-18, W. 2 M., at Pilot Butte, on Co.'s main line, Sask. Div., Moose Jaw Subdivision, Sask.

20635—October 22—Authorizing C.P.R. to construct Lacombe-Easterly Branch across twenty-three (23) highways, mileage 155.63 to mileage 180.61, Alberta.

20636—October 21—Authorizing C.P.R. to construct tracks to freight sheds in its yard at Peterboro, Ont., across King St., and to change alignment and grade of other two tracks across King St.

20637—October 22—Rescinding Order No. 17667, October 4th, 1912, in so far as it relieves C.P.R. from fencing from mileage 6.8 to 7.6 on east side of track. 2. C.P.R. fence portion of right-of-way from mileage 6.8 to 7.6 on east side of track, and put fences on west side of track in a proper state of repair; work to be completed within 30 days.

20638—October 22—Directing that C.N.O.R. at its own expense, construct a farm crossing on property of L. O. Christmann, of Beachburg, Ont., on Lot 8, Con. 4, Tp. Westmeath, Ont., by connecting old farm road with road crossing railway, by diverting it as shown in red on plan.

20639—October 22—Authorizing Niagara, St. Catharines and Toronto Ry. to operate its trains over crossing of G.T.R. at Welland Ave., city of St. Catharines, Ont., for construction purposes only, for a period of 2 months from date of this Order.

20640—October 22—Authorizing C.N.O.R. to construct, at its own expense, its railway across Dawes Road, between Tps. Scarborough and York, Co. York, Ontario.

20641—October 22—Authorizing C.N.O.R. to construct, at its own expense, across public road between Lots 34 and 35, Con. C, Tp. York, Ontario.

20642—October 23—Authorizing C.N.O.R. to construct, at its own expense, across the Don Mills Road in Lot 1, Con. 3 F.Y., Tp. York, Ontario, and authority herein granted to be without prejudice to right of Twp. to apply at any time for a subway at the point in question.

20643—October 23—Authorizing city of Toronto, Ont., at its own expense, to reconstruct bridges across G.T.R. & C.P.R. at Strachan Avenue subject to and upon certain conditions. And reserving leave to city to make such application as it may be advised for an Order requiring contribution from Ry. Cos., in so far as any additional expense for new tracks is concerned.

20644—October 22—Authorizing G.T.P.Ry. to construct spur on Twenty-first Street, between Short Avenue and C.N.R. right-of-way, in city of Edmonton, Alta., subject to certain conditions.

20645—October 23—Authorizing G.T.P. Branch Lines Company to construct, subject to terms of consent, highway across Tofield-Calgary Branch, S.W. ¼ Sec. 10-42-21, W. 4 M., mileage 58.8, Dist. North Alberta, Alta.

20646—October 23—Authorizing G.T.R. to reconstruct overhead bridge carrying town line road between Tps. Guelph and Eramosa, Co. Wellington, Ont., over Middle Division, 15th Dist. at Mile Post 44.61, at Rockwood, Ontario.

20647—October 23—Approving deviation of Lake Erie and Northern Railway line between stations 538-52.8 and 553-19.3, Tp. South Dumfries, Ontario, subject to certain conditions.

CONSTRUCTION NEWS SECTION

Readers will confer a great favor by sending in news items from time to time. We are particularly eager to get notes regarding engineering work in hand and projected, contracts awarded, changes in staffs, etc.
Printed forms for the purpose will be furnished upon application.

RAILWAYS—STEAM AND ELECTRIC.

Edmonton, Alta.—An act known as the light railways assistance act has been tabled in the Alberta Legislature, and provides, in the main, for the guaranteeing of bonds issued by companies constructing light railways in the province. It provides further that the guarantee shall not exceed 50 per cent. of the estimated cost of construction; and, in any event, shall not exceed $7,000 per mile of the mileage of such railways.

London, Ont.—The ratepayers have carried a by-law to raise $700,000 in debentures to electrify the London and Port Stanley Railway.

London, Ont.—Within two weeks the city council will nominate a commission of five members which will construct, equip, maintain, operate and manage the London and Port Stanley Railway. Semi-official information announces that Mayor Graham will be one member ex-officio, and the others in office the Hon. Adam Beck, Mr. Philip Pocock, Lieutenant-Colonel Gartshore and Mr. M. D. Fraser, K.C.

North Vancouver, B.C.—The Burrard Inlet Tunnel and Bridge Company are negotiating for the purchase of a railway right of way through the Seymour Indian Reserve, No. 2. The railway offers to pay $40,500 for 11½ acres of land, and $4,824.24 for improvements which will have to be destroyed or removed.

Ottawa, Ont.—In January, 1914, the residents of the town of Eastview will vote upon the question of extending the Ottawa Electric Railway line into Eastview. To perfect the scheme, Eastview is prepared to offer O.E.R. a bonus of $25,000.

▲ **Ottawa, Ont.**—Tenders will be received up till November 10th, 1913, for the construction of a line of railway from North Sydney to Leitches Creek, N.S. Plans and specifications may be obtained from the Assistant Deputy Minister and Secretary, Department of Railways and Canals, Ottawa, Ont., L. K. Jones, Esq.

Quebec, Que.—The Government has decided to proceed with the construction of the Transcontinental Railway tunnel from Lampson's Cove to St. Malo in Quebec city; and in the opinion of leading lawyers, the contracts will have to be awarded to Mr. M. P. Davis.

Toronto, Ont.—The Board of Railway Commissioners has still under consideration the plans of the C.N.R. for the single track across the city, the part being debated which would run for three miles within the city limits, and would add eight new railway crossings on city streets.

+—Vancouver, B.C.—MESSRS. McARTHUR BROTHERS secured the contract for the construction of the joint section of the Hope Mountain line of the Kettle Valley railway.

Winnipeg, Man.—While in this city, Sir Thomas Shaughnessy denied the report from Milwaukee, Wis., that the C.P.R. would electrify its entire system. It is the intention, he stated, to electrify Roger's Pass tunnel; and should this prove successful in operation, to extend the electrification over the mountain division from Revelstoke to Field, B.C.

Yorkton, Sask.—Le Pas Board of Trade has written the Yorkton Board of Trade urging the endorsation of a resolution calling on the Government of Canada to adopt means to compel railways now holding charters for branch lines connecting with the Hudson Bay road, to commence construction of same under penalty of having said charters revoked.

GARBAGE, SEWAGE AND WATER.

London, Ont.—The city of London has carried the by-law for the construction of storm sewers. This will mean that the city must issue debentures to the extent of $400,000.

London, Ont.—Working plans and specifications for the storm water drainage construction as well as for the reinforced concrete protection for the river embankment, will be completed during the winter months, so that contracts may be let and construction started in the spring. It is expected that the storm water system construction will be extended over four years with annual expenditures of $100,000. A $75,000 extension to the existing sanitary system with disposal plant for the East End will be considered this winter and work commenced next year. Mr. Willis Chipman, of Toronto, is consulting engineer for the work, which will be carried out under the London City Engineer's Department.

London, Ont.—Plans for the extension of the city garbage are being perfected, so that by the beginning of the year a large new territory will be served.

▲—**Ottawa, Ont.**—Tenders will be received up till November 6th, 1913, for the construction of the West End inter-

epting sewer. Plans and specifications may be obtained from Arch. Currie, City Engineer, Ottawa, Ont.

Regina, Sask.—The works committee has decided upon several extensions to sewers and water mains to be finished this year, notably the extension of sewer to serve the Armour abattoir.

Regina, Sask.—The city council of Regina has agreed upon extensions to the municipal sewer system, amounting in all to $6,206.30.

+—Toronto, Ont.—The city council has sanctioned the acceptance of the tender of the GAWNE CONTRACTING COMPANY for the construction of Section No. 2 of Danforth Avenue storm sewer at a cost of $32,093.

Vancouver, B.C.—The Saanich council has decided by a majority vote of four to three to approve the tentative agreement with the Vancouver city council for participation in the Northwest trunk sewer system at a cost of about $52,000. The proposal is to be submitted to the ratepayers in the form of a by-law. The cost of connection with the Northeast sewer was set at $21,122.

Vancouver, B.C.—The waterworks committee has passed recommendations for the laying of $56,865 worth of water mains throughout the city. However, from 60 to 70 per cent. of this amount has already been expended in buying the pipe.

Winnipeg, Man.—Mr. A. F. D. MacGachen, manager of the Bank of Montreal, has announced the willingness of his institution to finance the entire $13,500,000 loan which is required by the Administration Board of the Great Winnipeg Water District project. The account is to be operated at present on the overdraft principle, and the necessary funds will be available wherever they may be drawn upon.

LIGHT, HEAT AND POWER.

Brantford, Ont.—The Dominion Power and Transmission Company have under consideration a plan to develop 2,500 horsepower at Mohawk Lake to take care of its peak load in Brantford, and to provide against emergencies.

Edmonton, Alta.—The city commissioners have approved the [illegible] of Superintendent Orm-by to install at once a temporary light [illegible] level bridge and to charge the cost to the [illegible] Company. This company has not [illegible] with the city on July 1st, 1913, for [illegible] standards, which were to be delivered [illegible] days.

Edmonton, Alta.—The city commissioners have authorized Superintendent Perry to submit a report showing what new equipment is required at the power house, and including plans, diagrams and specifications so that tenders can be called and that portion of the work started.

Fort William, Ont.—The city council has officially appointed Professor Herdt of Montreal, as the city's arbitrator on the arbitration commission of three which is to determine the actual comparative cost of electrical energy as supplied to the city of Fort William by the Kaministiquia Power Company with the Hydro-Electric Commission, acting as intermediary. The Kaministiquia Power Company must appoint an arbitrator within ten days, and the city and company together will select the third.

Guelph, Ont.—The city council has passed a resolution adopting the recommendation of the Railway and Manufactures Committee, which is as follows:—"Your committee recommend that the Hydro-Electric Power Commission of Ontario be requested on behalf of the municipal council of the city of Guelph to inquire into, examine and investigate and report upon the cost of constructing and operating an electric railway from Hespeler, connecting with Puslinch Lake, through Guelph to Elora, Fergus and Arthur, and also from Arthur connecting with Mount Forest, through the Beaver Valley to Meaford or Thornbury; upon the municipalities, the inhabitants of which will be served by such railway; upon the population of each of such municipalities as shown by the last enumeration thereof by the assessors; upon an estimate of the probable revenue from the railway; and upon the practicability of the undertaking and its economic value to the localities served by it, as provided for in section 3 of the Hydro-Electric Railway Act."

London, Ont.—An agreement has been reached between the Street Railway Company and the city of London, by which the company will take power from the city, providing that the agreement is approved by the Hydro-Electric Commission in Toronto. The price agreed upon was $36 a horsepower for alternating current, and $28 for direct current. The amount of power will be about 600 or 700 horsepower, but later the entire system using over 1,000 horsepower may be operated by Hydro-Electric current. This arrangement will necessitate the installation of converting apparatus in the Horton Street plant to convert the Hydro power into direct current, suitable for the use of the railway company.

Medicine Hat, Alta.—The city council passed unanimously the recommendation of a by-law providing $150,000 for extension to the electric power plant, which will be submitted to ratepayers on November 21st; also a by-law to be submitted upon the same date for an expenditure of $12,000 to furnish apparatus for the new fire station, to be erected next year upon the hill.

Nelson, B.C.—It has been announced that the construction of the new units at the plant of the West Kootenay Power and Light Company at Bonnington Falls, which is to supply power for the Rossland-Castlegar line, when that portion of the C.P.R. has been electrified, will commence about January 1st, 1914. The contract for electrification has been let, and the new units for the plant are being built.

North Battleford, Sask.—The city of North Battleford has ordered a thorough investigation to be made immediately as to the possibilities of developing power at a point three miles west of the city on the North Saskatchewan River. The proposition of erecting a wall, 100 feet high, across the river is being considered. Only in a few places would this necessitate the construction of retaining walls; for the banks of the river from North Battleford to Edmonton are high and precipitous, and between these two points there is a drop of about 700 feet in the river. It is believed that the scheme would allow of the production of 40,000 horsepower, at a reasonable figure. The estimated cost of such an undertaking, including a lock in the wall at North Battleford enabling navigation to pass, is fixed at $30,000,000.

Ottawa, Ont.—The department of railways has been advised that a part of the wireless telegraphic equipment which was lost in the wreck of the steamer "Cerenus," when en route to Hudson Bay, has been salvaged. There is a possibility that this will be erected so as to establish wireless connection with Port Nelson this winter.

Ottawa, Ont.—Ottawa local contractors for excavation work will urge that the contracts for the new pipe line to Thirty One Mile Lake be for short stretches similar to the method used in the construction of railways. To let one contract for the entire excavation would exclude contractors unable to finance such an undertaking.

△ **Ottawa, Ont.**—Tenders will be received up till November 4th for the furnishing and installing of the electric lighting systems required in connection with the equipment of the N.T.R. car shops at Transcona, Man. Plans and specifications may be obtained from W. J. Press, Mechanical Engineer, Ottawa, Ont. Signed, P. E. Ryan, Secretary of the Transcontinental Railway Commissioners, Ottawa.

Ottawa, Ont.—Tenders will be received up till November 8th for supplying four 7-foot standard cast-iron lighthouse lanterns to be delivered free of charges at the Dominion Lighthouse Depot, Prescott, Ont. Plans and specifications may be obtained from Alex. Johnston, Esq., Deputy Minister of Marine and Fisheries, Ottawa, Ontario.

Owen Sound, Ont.—The city council of Owen Sound has carried a resolution authorizing the Mayor and Clerk to sign the contract for the supply of 1,200 horsepower by the Hydro-Electric Power Commission. The price is not to be in excess of $31 per horsepower, according to the estimate of the commission's engineers. The plant is to be commenced as soon as material can be placed upon the ground next spring. This winter plans and specifications will be prepared, and contracts for various branches of the work awarded. The town will retain for some time the old steam plant, which will be used for cutting down the peak load in the winter months, when the power and light loads overlap in the evenings.

Saskatoon, Sask.—The City Commissioners have informed the council that Saskatoon is in a position to supply the Dominion Government Interior Elevator upon which work has already commenced with electric power at the low rate of 1.6 cents per kilowatt hour.

St. Catharines, Ont.—The citizens of St. Catharines give every evidence of carrying, with a large majority, the by-law to install a municipal hydro power plant at a cost of $116,000, which will be submitted in January next.

Winnipeg, Man.—The Winnipeg Electric Railway Company has secured the Great Falls Power Company's waterfall on the Winnipeg River, situated midway between Lac du Bonnet, the present site of the railway company, and the mouth of the river.

Winnipeg, Man.—Consulting Engineers Heidt and Kennedy have submitted to the Board of Control their report upon the second transmission line to Point du Bois. In it they recommend that either the braced or the flexible tower systems be used, the former costing $600,000, the latter $520,000. The construction will doubtless not be commenced this year; since the present line has a capacity of 22,400 kilowatts, and the peak load at present is not more than 11,050 kilowatts and is not expected to exceed the capacity of the line before 1915.

Winnipeg, Man.—The city council of Winnipeg has passed a by-law for the expenditure of $1,000,000 to extend the power plant, and ratepayers will vote upon the proposition in December.

BRIDGES, ROADS AND PAVEMENTS.

▲ **Assiniboia, Man.**—Tenders will be received up till November 25th, 1913, for the construction of an asphalt pavement. Plans and specifications may be obtained from the office of the Municipal Engineer, Municipal Hall, St. Charles, Man. Signed, Frank Ness, Esq., Rural Municipality of Assiniboia, Kirkfield Park P.O., Man.

Calgary, Alta.—The city commissioners and parks superintendent will submit to the city council for its approval a scheme of boulevard improvement in the inside districts of Calgary which will necessitate the expenditure of $200,000. The expenditure, however, would be carried over a couple of years.

Edmonton, Alta.—The city council has agreed upon a program of construction of 17 subways, underlying the C.N.R. and G.T.P. tracks at Edmonton, including the raising of tracks, at a cost approximately $1,000,000. This is to be brought before the board of railway commissioners at its meeting in Edmonton at the end of the present month.

Essex County, Ont.—The county council is preparing a by-law to submit to the ratepayers, [illegible], for the raising of $1,000,000 for the purpose of building roads to connect all towns in the county. Engineer Hubert has recommended concrete roads for the purpose.

+ **Fredericton, N.B.**—Tenders are asked for the superstructure for the new bridge on the Canada Eastern branch of the Intercolonial Railway at Penniac, [illegible] to MESSRS G. F. BAIRD AND GEO. E. TOWIE of Fredericton. Their estimate was approximately $25,000.

+— **Fredericton, N.B.**—The contract for the substructure of a bridge at Covered Bridge on the Canada Eastern branch of the Intercolonial Railway, has been awarded to MR. MORRISON, contractor, whose tender was in the vicinity of $7,000.

Hull, Que.—The Hull city council has decided to begin at once the construction of the macadamized road between Hull and Gatineau Point. They reached this decision in conformity with a letter received by the corporation from the department of agriculture, dated October 16th.

London, Ont.—The installation of the storm water drainage system in London, means the construction of extensive and much-needed paving in the city streets. Proposals are now being considered for starting to lay 2½ miles of asphalt pavement to be completed next year.

Medicine Hat, Alta.—The city council will submit to the vote of ratepayers upon November 21st, a by-law for the appropriation of $50,000 to be used in grading and gravelling streets, and also for the purchase of the plant and machinery.

Montreal, Que.—The Board of Control have contracted for the 1914 supply of asphalt at a price lower than the city has ever before paid, the cut in prices being over $5 a ton compared with what the city was paying a few years ago.

▲— **Ottawa, Ont.**—Tenders will be received up till November 4th for the erection of a temporary bridge over the Rideau River north of the present Billings Bridge. Plans and specifications may be obtained from Archibald Currie, City Engineer, Ottawa, Ontario.

Ottawa, Ont.—The [illegible] Ontario Highways Commission has been [illegible] Ottawa, representatives from the counties of Carleton, Prescott, Russell, Dundas, Stormont, Glengarry, Lanark, Leeds, Grenville and Renfrew being present. The commission is endeavoring to gain first hand information regarding the local needs of the people of the province.

Ottawa, Ont.—Tenders will be received up till November 4th, 1913, for the erection of a temporary bridge over Rideau River, north of the present Billings Bridge. Plans and specifications may be obtained from Archibald Currie, City Engineer, Ottawa, Ont.

South Vancouver, B.C.—Councillor Dickenson has announced his intention of bringing in a by-law for the widening of Victoria Road from Kingsway to No. 1. road.

South Vancouver, B.C.—The board of works has recommended an additional $1,000 to be used for the completion of improvements on boulevards, of repairs on sidewalks, and of grading work at intersections of Westminster Road.

Stratford, Ont.—A deputation of property owners on McPherson Heights has submitted a proposition to the city council for the opening of William Street East from James Street, for the closing of the survey of Frank Street, and the assurance of the construction of a bridge over the river at either Front or Queen Street. The proposal has been referred to the board of works.

Toronto, Ont.—Mr. George J. Castle has written to the city Board of Control suggesting that, when the widening of Yonge Street is undertaken and the subway built at North Toronto Station, elevated sidewalks should be constructed so that pedestrians would not have to walk down one hill and climb another in passing through the subway. This he claims would save $250,000 for the city.

+— **Toronto, Ont.**—The city council has awarded to the Contracting Company of Works the contract for a 60-foot reinforced concrete arch span between Centre Island and Olympic Island.

Toronto, Ont.—The city council has decided to widen Broadview Avenue to 80 feet from Danforth Avenue to the north city limit, at a cost of $[illegible].

Toronto, Ont.—Tenders will be received up till November 4th, 1913, for the construction of asphalt, brick block, bitulithic and concrete pavements and for sewers. Plans and specifications may be obtained from the Chairman of the Board of Control, R. C. Harris (Mayor), Toronto, Ont.

Windsor, Ont.—The county council of Essex has prepared a by-law for submission to the ratepayers of the county to be submitted at the time of the general elections, to provide for raising $[illegible] to be devoted to the construction of permanent [illegible] of concrete material selected by Provincial Engineer [illegible], [illegible] of the county.

INDUSTRIAL WORKS.

Calgary, Alta.—[illegible] for [illegible] 1,000 k.w. synchronous motor [illegible]. Plans and specifications may be obtained from J. M. Miller, Esq., City Clerk, Calgary, Alta.

Cornwall, Ont.—[illegible] received here that the St. Lawrence River Power Company has secured permission from the government authorities at Washington to dredge the Grasse River from the power house to the river's mouth, a distance of nine miles. The work is to be done at the company's expense, and is to be commenced at once. Work is to be commenced at Massena Centre, the shallowest part of the river; and before a dredge can be operated, it will be necessary to build an electric power transmission line to this point.

Edmonton, Alta.—Premier Sifton has introduced in the Legislature a bill for the proposed loan of $3,000,000, of which $1,000,000 is to be utilized in telephone extensions, $1,000,000 for the Farmers' Co-Operative Elevator Company, and $1,600,000 for public works throughout the province.

Edmonton, Alta.—An English company of capitalists, with Sir John Jackson at its head, has been expending $75,000 with a view to gauging accurately the power possibilities of the Saskatchewan River at Rocky Rapids, and now intend to erect a large dam at the rapids for the purpose of supplying power for the cities and towns within a large radius.

London, Ont.—The ratepayers of the city of London have carried the by-law to raise $25,000 in debentures for a breakwater in West London.

London, Ont.—In connection with the great scheme of civic improvement in London, the call for tenders for ironwork, gulley gratings, manhole covers, etc., in quantity, is expected early in the year.

+—Montreal, Que.—Authentic word has come from Rio Janeiro that the Brazilian Government has signed its acceptance of the design and price submitted by SIR JOHN JACKSON, LIMITED, for the Rio port works. The estimated cost was $7,500,000. This is but the beginning of work on harbor extension at Rio Janeiro, which will total an expenditure of not less than $20,000,000.

+—Montreal, Que.—The Board of Control has awarded to the CANADA FOUNDATION COMPANY the contract for the completion of foundation of the pump station at a cost of $20,000.

North Battleford, Sask.—An agitation is being made by numerous boards of trade to persuade the Government to take immediate steps to assure navigation, both practical and economical, on the North Saskatchewan River from Edmonton to Lake Winnipeg. This would create a waterway across the entire prairie which would affect materially the cost of transportation.

Orillia, Ont.—The Water, Light and Power Commission, represented by Messrs. J. B. Tudhope and C. H. Hale, has asked the council to consider the passing of a by-law to raise $80,000 for installation of new machinery and equipment in the new power house to be built at Swift's Rapids. The commission wish to be certain of the town's attitude before signing the agreement being entered into with the Department of Railways and Canals.

▲—Ottawa, Ont.—Tenders will be received up till November 21st for the construction of harbor and river improvements at Fort William, Ont. Plans and specifications may be obtained from W. P. Merrick, Esq., District Engineer, Fort William, Ont. Signed, R. C. Desrochers, Secretary, Department of Public Works, Ottawa, Ont.

+—Ottawa, Ont.—The contract for section 2 of the Welland Ship Canal has been awarded to BAWDRY, YERBURGH AND HUTCHISON, of London and St. Catharines, the contract price being approximately $5,500,000. The advertisements for section 4 of the canal are expected to be issued at once.

Ottawa, Ont.—According to the intimation of the Hon. Robert Rogers, the Government will appoint at an early date a commission to inquire into the economic possibilities of the Georgian Bay Canal.

Ottawa, Ont.—Tenders will be received up till November 12th, 1913, for the construction of a wharf at Rocky Point, West River, Queen's Co., P.E.I. Plans and specifications may be obtained from the Department of Public Works, Ottawa, Ont. R. C. Desrochers, Secretary.

Ottawa, Ont.—The city engineer has recommended that heavier covers be put on 1,010 catch basins of the old style in the city, so that they may be rendered more safe. This would necessitate an expense of $10,000.

Ottawa, Ont.—The city Board of Control has decided to recommend that $300 be given by the city towards the Georgian Bay Canal campaign. This amount was subscribed also by Pembroke.

Ottawa, Ont.—It is announced from Ottawa that tenders are to be called at an early date for the construction of the 15-inch hydraulic dredge for use on the Arrow Lakes. The design submitted by Cartwright, Matheson and Company, of Vancouver, has been accepted by the Dominion Government The apparatus will be used for clearing a channel through the Narrows between the upper and lower Arrow Lakes from Nakusp to Killarney, in order to make possible navigation throughout the season. The operations will be supervised by J. P. Forde, government engineer.

Ottawa, Ont.—Tenders will be received up till October 31st for the delivery of track ties for the year 1914. Plans and specifications may be obtained from the office of General Tie and Timber Agent, Canadian Government Railways, Moncton, N.B. L. K. Jones, Secretary, Department of Railways and Canals, Ottawa, Ont.

Ottawa, Ont.—Tenders will be received up till December 9th, 1913, for the construction of wharfs at Victoria Harbor, B.C. Plans and specifications may be obtained from R. C. Desrochers, Esq., Secretary, Department of Public Works, Ottawa, Ont.

Ottawa, Ont.—Tenders will be received up till November 17th, 1913, for the construction of a wharf at Ainsworth, B.C. Plans and specifications may be obtained from the Department of Public Works, Ottawa. R. C. Desrochers, Secretary.

Quebec, Que.—Hon. R. L. Borden, while speaking at dinner in Quebec, made the assertion that the Dominion Government had acquired three miles of waterfront extending from Sillery to Cape Diamond, and that one of the largest and finest drydocks in the world was to be constructed at Lauzon. According to the statement compiled by the experts of the Department of Public Works, no larger dock is in existence or in contemplation in any British or American port than that which is being commenced within the limits of Quebec harbor.

+—Quebec, Que.—The contract for the Quebec drydock, at an estimate of $2,721,116, has been awarded to MR. M. P. DAVIS.

+—Saskatoon, Sask.—SHANNON BROS. AND CASSIDY of Saskatoon have been awarded the contract for excavating and building the concrete foundation of the new school in Mayfair section of the city, their tender estimate being $4,000.

Saskatoon, Sask.—Plans and specifications are being completed by the C.N.R. for a pumping station in Saskatoon at an estimated cost of $15,000. The company purpose to supply water to the tank, round house and engines at a lower rate than they are forced to pay to the city.

+—Toronto, Ont.—The contract has been awarded the THOR IRON WORKS, LIMITED, of Toronto, by the Canadian Mining and Finance Company for a stand pipe at Timmins, Ont. The stand pipe will be 20 feet in diameter, 95 feet in height and 225,000 gallons in capacity. Of this capacity 50,000 gallons will be held as a reserve for fire protection purposes at the top of the stand pipe by installing a hemispherical bottom about 15 feet from the top. The pipe is to be erected before winter sets in.

Vancouver, B.C.—Messrs. Hendry, McFee and McConnell are having constructed at the Wallace Shipyards a rock drill barge, which will cost about $25,000, and which will be used in connection with the construction of the Dominion Government wharf at Burrard Inlet.

+—Victoria, B.C.—McDONALD, GODSON AND COMPANY, the lowest tenderers for steel rivetted pipe in connection with the Sooke water scheme, has been awarded the contract, and will erect a local factory and do the work in Victoria.

Winnipeg, Man.—Tenders will be received up till November 15th, 1913, for the supply and installation of five complete pumping units, together with step down transformers, switch board and accessories. Plans and specifications may be obtained from the City Engineer, 223 James Avenue, Winnipeg, Man. Signed, M. Peterson, Esq., Secretary, Board of Control, Winnipeg.

MISCELLANEOUS.

Hamilton, Ont.—Managing director W. C. Hawkins of the Dominion Power and Transmission Company has announced officially that the company will build an auxiliary plant at the foot of James Street on the bay front, to develop 90,000 horsepower of electricity, and that the plant and equipment will cost $3,500,000. The work is to be commenced upon the construction next year, so as to have the plant in operation by next autumn. This plant will remove all possibilities of interruption by needle ice, and will always be in condition to supply power at short notice.

▲—Ottawa, Ont.—Notice is given that the time for the reception of designs in the first competition for the erection of Departmental and Court Buildings, is extended to April 2nd, 1914. R. C. Desrochers, Secretary, Department of Public Works, Ottawa, Ont.

Victoria, B.C.—The city council has authorized improvements to the city's electric light plant, which will provide workshop facilities for the employees. The building inspector is to submit an estimate and cost.

Barrett Specification Roofs

Last Longest—Cost Least

THE proper unit in comparing the values of roofings is the cost-per-foot-per-year-of-service.

To have a low unit cost a roofing must be—

1st. Inexpensive to build,
2d. Inexpensive to maintain, and
3d. Of great durability.

Barrett Specification Roofs are—

1st. The ***least*** expensive of all permanent roofs to build,
2d. They cost ***nothing*** to maintain, and
3d. They usually last, without repairs or leaks, ***20 years*** or over.

The net result of these three factors is a unit cost of about ¼c. per foot per year of service. This is a lower unit cost than ever attained by any other class of roofing.

Accordingly, Barrett Specification Roofs are in almost universal use on buildings such as illustrated herewith, where unit costs are intelligently studied.

Herald Building
Montreal

Architects—Brown & Vallence, Montreal
G. C. Nicholson & Co., Montreal
Roofers—Metal Shingle & Siding Co., Montreal

Copy of the Barrett Specification with tracing ready for incorporation in your building plans sent free on request. Address nearest office.

Special Note

We advise incorporating in plans the full wording of the Barrett Specification, in order to avoid any misunderstanding.

If any abbreviated form is desired however, the following is suggested.

ROOFING—Shall be a Barrett Specification Roof laid as directed in printed Specification, revised August 15, 1911, using the materials specified and subject to the inspection requirement.

THE PATERSON MANUFACTURING COMPANY, LIMITED

MONTREAL TORONTO WINNIPEG VANCOUVER

THE CARRITTE-PATERSON MANUFACTURING COMPANY, LIMITED

ST. JOHN, N.B. HALIFAX, N.S. SYDNEY, N.S.

CURRENT NEWS.

Aylmer, Ont.—The contract for pavement which has been held by P. Secord and Son of Brantford, has been brought to a successful completion. The work has been carried on throughout most of the summer, and only one block of pavement, where the earth is still too loose for operations, has been left until next season.

Edmonton, Alta.—The Legislature is being asked to consent to the change of the name, Bassano Electric Railway Company, to Bassano and Bow Valley Railway Company. Also the promoters of this railway and the Alberta Interurban Railway will ask for a guarantee of securities from the Government under the Light Railways Assistance Act.

Fredericton, N.B.—Good progress is reported by the Foundations Company, Limited, upon their work at the Fredericton-St. Mary's highway bridge. The 18-foot concrete footing for the new draw span piers has been completed, and the masonry work commenced. The old span, which sank some 150 feet down the river from the bridge, is being removed.

Hamilton, Ont.—The Ottawa Construction Company, which is building the revetment wall extension at Hamilton Bay, has employed the largest hydraulic dredge on the Canadian lakes. Before winter, this dredge is to have completed a channel 1,100 feet long, 700 feet wide, and 21 feet deep at the foot of Wellington Street, where the new extension ends; and, in addition, a channel 600 feet to the east in preparation for the time when the wall is extended east of Wellington Street.

Kamloops, B.C.—The Canadian Northern Pacific Railway Company is commencing the construction of its second bridge over the North Thompson, above Kamloops. It is to consist of seven 80-foot spans. Steel on the railway construction has been laid from Port Mann to Nine Mile Creek, 125 miles from Port Mann, and also north of Kamloops for a distance of 80 miles. Rails have been laid 205 miles west of Edmonton.

Medicine Hat, Alta.—The city council are considering a by-law to provide $50,000 for gas wells and extensions for 1914. The object of the by-law is to put next year's council in a position to finance and perform necessary civic development work without delay. The city is considering also the widening of several portions of city streets.

Medicine Hat, Alta.—The Saskatchewan Bridge and Iron Company are commencing the construction of their plant west of Medicine Hat, which will be the first of its kind in Western Canada. Several carloads of steel have arrived in the city and have been hauled to the site of the building.

Montreal, Que.—Considerable agitation is being made in the city in an endeavour to submit to the Legislature a petition signed at least by 50,000 citizens as a protest against the present paving law.

Montreal, Que.—A commission comprised of Professor McLeod of McGill University, Mr. Arthur, surveyor, of Montreal, and Mr. C. R. Coutlee of Montreal, has been chosen to investigate and report upon the question of water levels on the St. Lawrence and the Great Lakes, with particular reference to the effect of the different schemes of water power development; the decision as to whether the headquarters of the commission shall be Montreal or Ottawa has been delaying procedure in operations.

Montreal, Que.—The installation of the new pump, No. 7, is almost completed at the city waterworks, Montreal. When this is in operation, 12,000,000 additional gallons of water will be supplied to the city daily. No. 6 pump, which is not working to its full capacity of an equal number of gallons, will then be stopped and repaired.

Montreal, Que.—According to the statement of Controller Lachapelle, the city and Montreal Tramways Company will not take up the question of a new franchise this year. Mr. McLeod, city traffic engineer, has not yet completed his report on the matter of franchises, and the recommendations connected therewith. At present, he is preparing a report for the relief in the present congestion in the outer wards; though the enforced cessation of work which is at hand will prevent much being done towards improvement of the Tramway Company's service in the outskirts until spring.

Montreal, Que.—The Hon. J. E. Caron states that the Government has constructed about 2,000 miles of macadamized roadway during the past season, and that the most of this work done has been on the King Edward highway. It is expected that this highway will be completed this fall.

Moose Jaw, Sask.—The work on the coal bunkers, coal carrier, and ash carrier systems at the power house, which had to be stopped early in the spring, is to be commenced again this fall. Much of the necessary material has been delivered, the coal bunkers inside the power house are fairly well completed; but the huge steel frame-work and the spur track for running in the cars are only commenced.

Moose Jaw, Sask.—The Eleventh Avenue subway which was commenced over a year ago, has reached completion and has been opened to vehicles and to the Street Railway traffic. A modern subway has been constructed at a total cost of $96,450, in which only the best of material has been used. The paving bricks are of a selected type, the drainage system provides for a collection of no surplus water at the lower portion of the subway; and granolithic sidewalks on both sides are provided with steel railings.

Moose Jaw, Sask.—Mr. F. B. Lane, C.N.R. bridge inspector, expresses pleasure at the progress made upon the C.N.R. bridge at Main Street in this city, and says that all possible haste will be made with the trestle bridge through the city.

Ottawa, Ont.—Tenders have been called for by the Dominion Government, to be in by November 5th, for plans and specifications for a grain elevator at Port Nelson of a 1,500,000 bushel capacity, to be located near to and to conform with the pier construction of the Department of Railways and Canals. When the Government has selected the type of building it deems advisable, construction tenders will be called.

Ottawa, Ont.—Mr. H. P. Mullarky, contractor for the section of the Canadian Northern Transcontinental Railway, between Ottawa and Pembroke, states that before severe cold weather sets in, steel will have been laid for 27 miles easterly from Pembroke. Two bridges over the Ottawa River have to be constructed along the line, one at Portage du Fort, and the other at Chatsfalls; and these are to be completed by next spring. This entire section of the transcontinental line is to be ready for operation in the fall of 1914.

Ottawa, Ont.—Investigations made in regard to the rainfall in the district tributary to the Trent Canal, show that the canal may become seriously affected by lack of water for the locks, if the Government does not take control of certain forest areas and protect them, as well as proceed with a program of reforesting.

Ottawa, Ont.—Mr. J. G. Kilt, president of the Morrisburg and Ottawa Electric Railway has stated that about six miles of the line running from Ottawa have been completed; and that the chief engineer has three staffs and about 50 teams engaged upon the roadbed construction.

Ottawa, Ont.—A gap of eight miles, about 208 miles east of Cochrane, is the only stretch remaining on the National Transcontinental line from Moncton to Winnipeg, where the laying of steel has not been completed. When this has been finished the eastern section of the railway, 1,804 miles in length, will be a unit of complete construction.

Outremont, Que.—Concerning the opening up of Van Horne Avenue to Mount Royal Heights, the town council decided to give the required notice for the undertaking, and, in consideration of the fact that the Tramway Company may be prevailed upon to extend its car service through to Mount Royal, to give the notice at once.

Port Arthur, Ont.—Grain is being received by the new Government elevator at Port Arthur. The formal opening of the structure has, however, not taken place, nor been yet arranged, owing to the uncertainty of the definite arrival in the city of the Hon. G. E. Foster, who will perform the ceremony.

Prescott, Ont.—On October 23rd, power was first transmitted to Prescott from Morrisburg, over the wires of the Hydro-Electric Power Commission. The power will light the streets and buildings of the town and also be used for the operation of machinery in small industrial establishments.

Prince Albert, Sask.—An investigation into the full nature and history of the Prince Albert power plant at Lacelle Falls is being made by a special committee in the endeavor to suggest finally, if possible, a solution to the difficulties confronting the city.

Prince Rupert, B.C.—The necessity of another port, to be situated north of Prince Rupert, and the urgency of put-

ting before the Government at Ottawa the need of a new harbor here, is being demonstrated by Mr. James Cornwall, ex-M.L.A. for the Peace River District, Alta.

Prince Rupert, B.C.—J. R. Stirrat, chief engineering contractor for the construction of the cement piers for the drydock to be built here, is in the city and is setting in operation the dredging at that part where the waters of Hay's Creek empty.

Redcliffe, Alta.—Since August 10th, over four miles of new water pipe have been laid in Redcliffe, according to the statement of City Engineer Askwith. He reports also that the water tank has had a thorough test and has been proven perfectly tight in spite of the great weight of the water and the numerous rivets. The new pump which has been installed is practically complete, and will soon be in operation.

Saskatoon, Sask.—Reports from Wakaw, Sask., state that construction engineers from a Chicago firm have placed orders for sand and gravel, and state that work on the Grand Trunk bridge crossing the North Saskatchewan River at St. Louis, and completing the entry of the road into Prince Albert, will start at once.

Sidney, B.C.—The new wharf constructed by the Provincial Government at the foot of Third Street, Sidney, which runs out to Robert's Bay for a distance of about 2,000 feet, has been completed and is being used for passenger traffic.

South Vancouver, B.C.—Complying with the order of the railway commissioners, the B.C.E.R. Company have begun the raising of Rupert Street bridge by an additional height of 2 feet 2 inches.

Vancouver, B.C.—The Pacific Dredging Company have commenced dredging operations for the foundation of the new Government dock in Burrard Inlet. About 250,000 cubic yards are to be excavated, and this will require several months' time.

Vancouver, B.C.—The Pacific Dredging Company, which secured the contract for dredging out the side of the new Government wharf in Burrard Inlet, has commenced the work.

Vancouver, B.C.—An endeavor is being made by the C.P.R. to have the Eastern section of its new station ready for occupancy by February 1st. When this part is complete, the old structure will be raised and the ground will be prepared for the rest of the new structure. At present, the steel on the eastern section is about completed. Foundations have been started for the overhead bridge from the foot of Granville Street and preparations are under way for placing piers on the waterfront for the other end of the bridge. Abutments have been laid for the second viaduct, which will extend from Burrard Street to the water and the foundations for the piers have been completed.

Vancouver, B.C.—Construction is reported as having commenced from both ends on the joint section of the Kettle Valley Railway between Hope and the Coquehalla summit. Contracts have been let, roads for transporting supplies and equipment have been built, and a large force of men has been employed to work upon clearing and grading. The greatest engineering difficulties in the construction will be met near the Pas. Here, in order to transport supplies to the right-of-way from the roadway near the summit, a cable train will have to be used. The road is, in some places, nearly 1,000 feet from the route, and goods will have to be lowered over a big bluff into the valley below.

Vancouver, B.C.—An agitation is being made in Moncton for the consideration on the part of the city and the railway management to do away with level crossings, which are intersected by the railway.

Vancouver, B.C.—There has been considerable delay in connection with the construction of the four east end viaducts at G.N.R. crossings. This has been due to the fact that the chief engineer of the railway commission would not attach his signature to the plans prepared and forwarded by Mr. Fellowes, until the G.N.R. Company had approved the plans. A further hindrance, however, has been the consideration of the amount of expenditure required to be met by the city. Though the G.N.R. has agreed to all the details concerning the extent of its amount of cost, $300,000, official notification has not been forwarded to the city. Accordingly, the legal department has notified the company that unless the city is given notice of the company's approval of the plans before October 27th, application is to be made to the railway commissioners to compel the G.N.R. to do so, when they meet here upon that date.

Vancouver, B.C.—Preparation is being made for setting out upon the extensive scheme of harbor improvement at Vancouver. Mr. L. Nelson, superintendent of the dredging department of the Public Works of Canada, with headquarters at Vancouver, has sent to Victoria the two chief operators to familiarize themselves with details of dredge operation. Mr. Nelson conferred with Mr. F. H. Shepherd, M.P., at Nanaimo, on Friday, in reference to the harbor improvements, and more particularly with regard to the installation of the Lobnitz rock crusher ordered from Scotland by the Dominion Government, for special use in the Nanaimo Harbor to remove certain rocks. The rock crusher is now being assembled on the mainland, this is in accordance with instructions received from Ottawa. The hull will be launched in about a week's time and it is expected that the crusher will be at work within 60 days.

Victoria, B.C.—From Heriot Bay to Shoal Bay the Government telephone line is complete, and the contract has been let for the laying of the cable across Okis Hollow Channel and Nodall's Channel. The entire line and the work on the Government trails is expected to reach completion soon after the end of October.

Victoria, B.C.—Mayor Morley has explained the delay in progress on the new Johnson Street bridge as due to difficulties and grades which still have to be settled with Chief Engineer of Railways Gamble, who is acting in the matter. The chief difficulty is stated to lie in the final decision between the Johnson Street or Cormorante Street route.

Victoria, B.C.—Difficulties in regard to the C.N.P. Railway's right-of-way, which have been delaying the progress of the contractors in the grading of the Victoria-Patricia Bay section, are being overcome, and it is reported that negotiations are reaching a final settlement, and that the company will be in complete possession of all the property required within a week. The road is expected to be ready for rough operation early in the new year; but until much detail work has been completed, a regular service cannot be installed.

Welland, Ont.—The Dominion Dredging Company, contractors for No. I. section of Welland Ship Canal, have commenced work upon the various buildings for their plant at Port Weller. The dredges and delver to be used by the company are on their way from Quebec. It is expected that the steam shovelling work will be started about November 1st. Meanwhile, cleaning, grubbing and wheel scraping is being done along the construction railway; and a new siding is to be built, for which several trainloads of ties have already been delivered to the N.S.T.R.

Winnipeg, Man.—Rapid progress is reported upon the construction of the new Provencher bridge. Number 6 pier has been commenced, and the contractors propose, by working throughout the winter, to have the bridge ready for traffic and for the laying of a double street car track late next fall.

NEW TRANSMISSION BOOKS

Lundquist—

Transmission Line Construction

By R. A. LUNDQUIST, E.F. 295 pages, 6 x 9, 183 illustrations, $3.00 (12 6) net, postpaid.

The details of high tension line construction collected by a man of experience. They are brought together for the engineer in the field. Full of practical ideas, suggestions, cost data and tables.

CONTENTS.—I.—Preliminary Work. II.—Location of Line-Surveys and Engineering. III.—Types of Construction IV.—Wooden Pole Construction V.—Steel Pole Construction. VI.—Steel Tower Construction. VII.—Reinforced Concrete Construction. VIII.—Special Structures. IX.—Cross-Arms, Hardware, Pins and Insulators. X.—Guying. XI.—Stringing Wire. XII.—Cost Data Typical Transmission Lines. XIII.—Organization and Tools.

Still—

Overhead Electric Power Transmission

By ALFRED STILL, Mem. A.I.E E., Inst. of E.E., etc., Assistant Professor of Electrical Engineering, Purdue University. 306 pages, 6 x 9, illustrated, $3.00 (12 6) net, postpaid.

A clear treatment of principles and calculations. It confines itself strictly to *the design of lines*, making no attempt to cover such questions as distribution systems for country or town, plant construction and the related subjects.

It aims to give "the reasons of things," to explain the derivation of practical methods and formulas in the simplest possible terms. Professor Still has been associated with hydro-electric and transmission projects in England, Canada and the United States. His wide experience enables him to view the problem broadly and emphasize the factors to be considered in planning an economical, safe and efficient line.

For Sale by The Book Dept., *The CANADIAN ENGINEER, 62 Church St., Toronto*

COAST TO COAST.

(Continued from page 663.)

Fort William, Ont.—The board of works adopted this year a new method of carrying out its civic improvements, e.g., the letting of the work by contracts instead of undertaking the work itself, hiring its foremen and laborers. The large list of works completed, and a saving both in time and money, have proven the success of the scheme.

Bassano, Alta.—On October 21st the gates of the six million dollar dam of the C.P.R., which was constructed to divert the waters of the Bow River for irrigating 30,000 acres of land around Bassano, closed without preliminary announcement or ceremony. A tidal wave swept back up the river, and the western river began to rise, the eastern to fall. The operation of the dam will back up the river for eight miles, and the process of filling to the height of the dam, 45 feet, will take four weeks' time.

Vancouver, B.C.—According to advices from the Boundary district, steel will be laid on the Kettle Valley Railway from Midway to the Summit, 76 miles west of Midway, by December 1st of this year. Track-laying is complete from Wolfe Creek, a point 65 miles west of Midway; but the building of three bridges within a distance of three miles will make progress much less rapid. The contractors believe that the link of the Kettle Valley between the present end of steel and Penticton will be connected late next summer.

Saskatoon, Sask.—In the opinion of Mr. M. L. Hovis, of Gibsonburg, Ohio, and of Mr. W. R. Martin, of Medicine Hat, Alta., competent experts on the matter of gas wells, the fields at Medicine Hat and Calgary, extend far to the eastward over the three prairie provinces, and are not purely local, as has been generally considered up to the present. They are preparing to place before the city council of Saskatoon a proposal to drill a gas well within the city limits, and there is a strong civic opinion in favor of giving the experiment a sufficient test.

Saanich, B.C.—The beginning of a scheme which involves an expenditure of $340,000, and which will complete 22 miles of bitulithic highways in Saanich was given a ceremonial opening by Mr. W. W. Foster, Deputy-Minister of Public Works. Members of the Victoria Automobile Association, representatives of Saanich and Esquimalt, and others interested, were present to hear the addresses of those who took part in the festival ceremony. Actual construction work is to be begun as soon as the weather is favorable; and a good amount of the work is expected to be available for tourists next summer.

Montreal, Que.—Major Hutchison, manager of the Montreal Tramways Company, has announced that before winter snow comes to stop operations, the company will have expended about $3,000,000 of the $3,750,000 appropriations set apart at the commencement of the year for the complete reorganization of the system. The company is endeavoring to provide a perfected traction system, more especially at present to affect the outlying districts, but also to relieve central congestion and to inaugurate a rapid and frequent service throughout the entire city and suburbs where the Tramway Company will operate.

Montreal, Que.—Macdonald College, Ste. Anne de Bellevue, has added to its curriculum of studies a course in road making. Professor G. E. Emberely, of the college, will lecture on the art of constructing dustless highways of various materials, and those taking this course will graduate as fully qualified road-builders. This branch of study is really a part of the agricultural course of the institution, though for a long time students have aided in the construction of thoroughfares throughout the college grounds. However, a very thorough course in this science is now to be given, with the idea of teaching the prospective farmer how to build and maintain the roads on his own farm and the roads bordering upon that.

Victoria, B.C.—Within a month, the Commission of Conservation for Canada will conclude its extensive investigations in British Columbia in regard to water powers. Mr. A. V. White, who has spent the best part of a year in the province inquiring into water resources, their location and power capacity, states that during the last three years the co-operative work of the Commission and the Lands Department of the Provincial Government has been in progress, and has resulted in the gathering of an immense volume of valuable information concerning the aggregate amount of water in the province, together with its various capacities. The season now closing is likely to be the last devoted to this subject in the province, as, in the opinion of Mr. White, the subject is wellnigh exhausted, and he believes that the commissioners will proceed with their report upon the material in hand at the closing down of the present year's work.

Winnipeg, Man.—On October 18th, the C.P.R. internal terminal elevator at Transcona, Man., began to sink, and for twelve hours proceeded in a steady collapse at a rate of two feet every ten minutes. Before engineers could effect a stoppage in the tilting, the bridge connecting the elevator and the transfer house had fallen, and when the lean of the structure became too great for the overhanging bulk, the massive Cupola containing the distributing machinery collapsed. Owing to the wreckage of this machinery, considerable difficulty will be experienced in efforts to remove the grain from exposed bins before navigation closes. The bins have so far held together as a unit, and the transfer house has not been affected. It is the opinion of J. C. Sullivan, chief engineer of the C.P.R., that something was wrong with the earth of the floating foundation upon which the elevator was constructed, and that this was not known or discovered when the foundation was laid.

Regina, Sask.—The Saskatchewan Highways Commission has expended this year over $1,500,000 in an extensive programme of provincial road and bridge construction of about 150 small bridges, many of wood and others of steel, 25 steel bridges with concrete foundations, and the new traffic bridge at Saskatoon, which alone will cost approximately $350,000,—of these bridges, some have been finished, and others are still in process of construction; and in all, the expenditure on bridges this year will be $500,000. Work on bridges will be continued far into the winter; but the frost, which has now gone several inches into the ground, is necessitating the calling in of road gangs. But this year not only has much been done to construct and improve traffic facilities for new town communities, which are established in Saskatchewan at the rate of one every week; but for the first time the road from Fleming, near the Manitoba boundary, to Swift Current has been put into a condition suitable for continuous travel.

Quebec, Que.—The Premier of Canada, accompanied by many distinguished members of Government and prominent citizens of Quebec, on October 22nd proceeded on a tour of inspection to Cape Rouge to see the Quebec bridge in course of construction, and thence along the river front to observe the work completed in connection with the Transcontinental Railway terminus as well as to view the south site entrance of the railway tunnel to be built. The bridge, it is declared, will be the finest bridge structure in the world. It will measure 3,239 feet in all, the main span 1,800 feet, the width from centre to centre of the trusses 88 feet, and the clearing height above high water 150 feet. The masonry is especially

massive in design, and the bridge will provide a width for two railway tracks and two-foot walks. The construction is being carried out by a commission comprised of C. N. Monsarratt, chairman and chief engineer; Messrs. Ralph Modjeska and C. C. Sneider; and is expected to be completed in 1917.

CATALOGUES RECEIVED.

(Continued from page 662.)

Sanitation at Mining Villages.—Illustrated pamphlet by Dwight E. Woodbridge, showing what has been accomplished by better sanitation at mining villages in the Birmingham district, Ala. Issued under the direction of Joseph A. Holmes, Director, Bureau of Mines, Washington, D.C.

The Influence of Inert Gases on Inflammable Gaseous Mixtures.—Illustrated pamphlet, showing experiments in the steel explosion cylinder, limits to explosibility, and the application of results. Published by J. K. Clement under the authority of the director, J. A. Holmes, of the United States Bureau of Mines.

Vitrified Segment Sewer Block.—This product of the American Sewer Pipe Company, Akron, Ohio, handled in Western Canada by Vitrified Clays, Limited, Calgary, is well described in Catalogue "C" of 24 pages, giving types, sizes, measurements, results of tests, endorsations, price lists, fittings, etc.

Census of Mineral Production of Canada.—A bulletin giving the fifth census taken of mineral production, e.g., for the year 1910 as enumerated under date of 1st June, 1911. Published by authority of Hon. Geo. E. Foster, minister of Trade and Commerce, and compiled by Archibald Blue, chief officer of the Census and Statistics Office, Ottawa.

Direct Current Railways.—A large, handsomely illustrated 132-page book under the name, "Bulletin No. 4958," General Electric Company, descriptive of 1,200, 1,500 and 2,400-volt direct current railways. The catalogue contains a full and comprehensive description of all apparatus and equipment pertaining to operation. Numerous installations are described and illustrated.

Light Mountain Transit.—A well-illustrated, carefully edited 32-page booklet has been received descriptive of the light mountain transits manufactured by W. & L. E. Gurley, Troy, N.Y. The catalogue is interesting in that it covers a wide range of transits adaptable to mountain or mine survey work, where portability is essential, and in this make of instrument the demand for lightness as well as quality appears to be well met.

Live Steam Separators.—Section A of an illustrated series of five pamphlets, comprising a bulletin which includes the introduction and general description of Cochrane Separators under the following heads: Section A, Live Steam Separators; Section B, Live Steam Separators and Receivers; Section C, Oil Separators; Section D, Vacuum Oil Separators; Section E, Low-pressure Receiver Oil Separators. Issued by the Harrison Safety Boiler Works, Philadelphia, Pa.

Road Rollers and Tractors.—Chambers, Limited, 152 Bay Street, Toronto, are distributing catalogues of the road rollers, steam-driven road locomotives and oil tractors manufactured by John Fowler & Company, of Leeds, England. "Fowlers'" are one of the biggest manufacturers of these lines of machinery in England, employing over four thousand men. They recently secured an order for six rollars from the city of Toronto, which was probably the largest single road roller contract ever awarded by a Canadian municipality.

IRRIGATION IN INDIA.

In the last ten years no less than 10,000 miles of canals had been opened in India, bringing the total in active use up to 53,000 miles. Thirty years ago the area served by irrigation in India amounted to about 11,000,000 acres. Twenty years later the total stood at about 19,000,000, and at present it amounts to about 23,000,000, which, when the works now under construction are completed, will be increased to 27,000,000. There are other large projects under consideration which will add another 10,000,000 acres to the irrigated areas. The Irrigation Commission estimates that a district insured by irrigation would give protection against famine to an area from twice to four times as large, and on this assumption the irrigation works in India may be said to protect a total area of considerably over 100,000 square miles—an area about equal to that of the British Isles.

Tuke and Bell, Limited, of London, England, have vacated their London office temporarily, as their building has been pulled down owing to the widening of Leadenhall St. They request all correspondence to be addressed to them at 509 High Road, Tottenham, London, N.

DEPARTMENT OF RAILWAYS AND CANALS, CANADA.

WELLAND SHIP CANAL.

SECTION No. 5.

NOTICE TO CONTRACTORS.

Sealed Tenders, addressed to the undersigned and marked "Tender for Section No. 5, Welland Ship Canal," will be received at this office until 12 o'clock noon on **Tuesday, November 18th, 1913.**

Plans, specifications and form of contract to be entered into can be seen on or after this date at the office of the Chief Engineer of the Department of Railways and Canals, Ottawa, and at the office of the Engineer in Charge, St. Catharines, Ontario.

Copies of plans and specifications may be obtained from the Department on the payment of the sum of fifty dollars. To bona fide tenderers this amount will be refunded upon the return of the above in good condition.

Parties tendering will be required to accept the fair wages schedule prepared or to be prepared by the Department of Labor, which schedule will form part of the contract.

Contractors are requested to bear in mind that tenders will not be considered unless made strictly in accordance with the printed forms, and in the case of firms, unless there are attached the actual signature, the nature of the occupation, and place of residence of each member of the firm.

An accepted bank cheque on a chartered bank of Canada for the sum of $100,000.00 made payable to the order of the Minister of Railways and Canals, must accompany each tender, which sum will be forfeited if the party tendering declines entering into contract for the work, at the rates stated in the offer submitted.

The cheque thus sent in will be returned to the respective contractors whose tenders are not accepted.

The cheque of the successful tenderer will be held as security, or part security, for the due fulfilment of the contract to be entered into.

The lowest or any tender not necessarily accepted.

By order,

L. K. JONES,
Assistant Deputy Minister and Secretary.

Department of Railways and Canals,
Ottawa, 29th October, 1913.

Newspapers inserting this advertisement without authority from the Department will not be paid for it.—50010.

The Departmental House for Mechanical Goods HAS ARRIVED

What the department store is to the general public our "Mechanical Goods Departmental House" is to the engineering and contracting field.

The public takes the efficient and time-saving merchandising methods of the department store as a matter of course. In the mechanical world we offer the same convenient service.

Why lose time "shopping" around town when you can buy anything you want and of a standard quality all under "one roof"?

Our business is divided into a number of departments in order that it may be handled most expeditiously and to the best interests of our customers.

In addition to the staple articles pertaining to each department we handle a great many specialties, some of which are listed below

SCALE DEPARTMENT
- Fairbanks World-famous Scales, of all types and sizes

VALVE AND STEAM GOODS DEPARTMENT
- Fairbanks Brass and Iron Valves
- Pratt and Cady Valves
- Foster Reducing Valves
- American Steam Pressure Gauges
- Wainwright Joints
- Penberthy Oilers
- Strong Steam Traps
- Wainwright Heaters
- Burt Exhaust Heads
- American Safety Valves
- Trident Water Meters
- Palmetto Packing
- Durabla Packing
- Oster Stocks and Dies
- Tools and Fittings

ENGINE DEPARTMENT
- Fairbanks-Morse Oil Engines
- Fairbanks-Morse Marine Engines
- Fairbanks-Morse Tractors
- Farm Machinery
- Motor Boat Supplies
- Automobile Supplies

PUMP DEPARTMENT
- Fairbanks-Morse Steam Pumps
- Power Pumps
- Goulds Power Pumps
- Hand Pumps
- Combined Engines and Pumps
- Spraying Outfits
- Air Compressors
- Suburban Water Systems

ELECTRICAL DEPARTMENT
- Fairbanks-Morse Generaters and Motors
- Edison Storage Batteries
- Suburban Lighting Outfits

MACHINERY DEPARTMENT
- Pratt and Whitney Tools
- Brown and Sharpe Tools
- McDougall Lathes
- Bertram Tools
- Machine shop tools of all kinds
- Wood Working Machinery

TRANSMISSION DEPARTM'T
- Fairbanks Wood Split Pulleys
- Universal Giant Shaft Hange
- Skefko Ball Bearings
- Nicholson Couplings

RAILWAY AND SUPPLY DEPARTMENT
- Fairbanks-Morse Motor Cars
- Elwell-Parker Trucks
- Barrett Jacks
- Arthur Koppel Industrial Ry. Equipment
- Fairbanks-Morse Air Compressors
- Fairbanks-Morse Hoisting Engines
- Fairbanks Trucks
- Milburn Lights
- Smith Concrete Mixers

SMALL TOOL AND SUPPLY DEPARTMENT
- Pratt and Whitney Tools
- Brown and Sharpe Tools
- Yale and Towne Hoists
- Alundum Grinding Wheels
- Crystolon Grinding Wheels
- India Oil Stone
- Parker Vices
- Union Chucks

SAFE AND TYPEWRITER DEPARTMENT
- Dominion Safes and Vaults
- Noiseless Typewriters

TRUCK DEPARTMENT
- Mack Trucks (gasoline)

TENDERS CALLED FOR

Sealed tenders addressed to the undersigned and endorsed "Tender for Construction of Wharfs at Victoria Harbor, B.C.," will be received at this office until 4 p.m., on Tuesday, December 9, 1913, for the construction of Wharfs at Victoria Harbor, B.C.

Plans, specification and form of contract can be seen and forms of tender obtained at this Department and at the District Engineers' offices at New Westminster, B.C.; Victoria, B.C.; Confederation Life Building, Toronto, Ont.; Post Office Building, Montreal, P.Q.; and on application to the Postmaster at Vancouver, B.C.

Persons tendering are notified that tenders will not be considered unless made on the printed forms supplied, and signed with their actual signatures, stating their occupations and places of residence. In the case of firms, the actual signature, the nature of the occupation, and place of residence of each member of the firm must be given.

Each tender must be accompanied by an accepted cheque on a chartered bank, payable to the order of the Honorable the Minister of Public Works, equal to five per cent. (5 p.c.) of the amount of the tender, which will be forfeited if the person tendering decline to enter into a contract when called upon to do so, or fail to complete the work contracted for. If the tender be not accepted the cheque will be returned.

The Department does not bind itself to accept the lowest or any tender.

By order,
R. C. DESROCHERS,
Secretary.

Department of Public Works,
Ottawa, October 27, 1913.

Newspapers will not be paid for this advertisement if they insert it without authority from the Department.—45197.

Sealed tenders addressed to the undersigned, and endorsed "Tender for Harbor and River Improvements in the Mission River, Fort William, Ont.," will be received at this office until 4 p.m., on Friday, November 21, 1913, for the construction of the Harbor and River Improvements.

Plans, specifications and form of contract can be seen and forms of tender obtained at this Department and at the offices of W. P. Merrick, Esq., District Engineer, Fort William, Ont.; J. G. Sing, Esq., District Engineer, Confederation Life Building, Toronto, Ont.; J. L. Michaud, Esq., District Engineer, Post Office, Montreal, P.Q.

Persons tendering are notified that tenders will not be considered unless made on the printed forms supplied, and signed with their actual signatures, stating their occupations and places of residence. In the case of firms, the actual signature, the nature of the occupation, and place of residence of each member of the firm must be given.

Each tender must be accompanied by an accepted cheque on a chartered bank payable to the order of the Honorable the Minister of Public Works, equal to ten per cent (10 p.c.) of the amount of the tender, which will be forfeited if the person tendering decline to enter into a contract when called upon to do so, or fail to complete the work contracted for. If the tender be not accepted the cheque will be returned.

The Department does not bind itself to accept the lowest or any tender.

By order,
R. C. DESROCHERS,
Secretary.

Department of Public Works,
Ottawa, October 22, 1913.

Newspapers will not be paid for this advertisement if they insert it without authority from the Department.—46879.

THE COMMISSIONERS OF THE TRANSCONTINENTAL RAILWAY.

NOTICE TO CONTRACTORS.

Tenders for the Installation or Completion of Electric Wiring System for the N.T. Ry., Car Shops, Transcona, Manitoba.

Sealed tenders, addressed to the undersigned and marked on the envelope: "Tender for Electric Wiring System," will be received at the office of The Commissioners of the Transcontinental Railway, at Ottawa, Ontario, until 12 o'clock noon of the 4th day of November, 1913, for the furnishing and installing of the Electric Wiring Systems required in connection with the equipment of the National Transcontinental Railway Car Shops at Transcona, Man., about six miles east of Winnipeg.

Plans may be seen and forms of tender and specifications obtained at the office of Mr. W. J. Press, Mechanical Engineer, Ottawa, Ont., and at the office of Mr. H. H. Pinch, Assistant Engineer, Transcona, Manitoba.

Persons tendering are notified that tenders must be made on the forms supplied by the Commissioners, and that each tender must be signed and sealed by all the parties to the tender, and witnessed, and be accompanied by an accepted cheque on a Chartered Bank of the Dominion of Canada, payable to the order of The Commissioners of the Transcontinental Railway, for a sum equal to five per cent. (5 p.c.) of the amount of the tender.

The cheque deposited by the party whose tender is accepted will be deposited to the credit of the Receiver-General of Canada as security for the due and faithful performance of the contract according to its terms. Cheques deposited by parties whose tenders are rejected, will be returned within ten days after the signing of the contract.

The right is reserved to reject any or all tenders.

By order,
P. E. RYAN,
Secretary.

The Commissioners of the Transcontinental Railway.
Dated at Ottawa, October 8, 1913.

Newspapers inserting this advertisement without authority from the Commissioners, will not be paid for it.—49048.

NOTICE TO CONTRACTORS.

INTERCEPTING SEWER.

Sealed tenders addressed to the Chairman of the Board of Control will be received by the Secretary of the Board of Control, City Hall, Ottawa, up to 4 p.m., Thursday, November 6th, 1913, for the construction of the West End intercepting sewer.

Any tender received after the above stated time will be declared informal.

Specifications and full particulars may be obtained on application at the City Engineer's office, City Hall, Ottawa.

The Corporation does not bind itself to accept the lowest or any tender.

ARCH. CURRIE,
City Engineer.

Ottawa, October 27th, 1913.

(For further Tenders see pages 86, 88 and 90.)

Insuring Pumps

against their destruction by fire requires engineering knowledge that is not needed in insuring dwellings, stores, etc.. We used the word "Pumps" only as an illustration. It requires sound engineering and expert insurance knowledge—combined in the one firm—to secure for any industrial or engineering firm the lowest possible insurance rates. Only a firm like ours—employing a staff of engineers—could appreciate your requirements—not only in fire insurance but also in special forms of insurance.

Correspondence solicited.

EIGHTH EDITION, Re-written and Enlarged
TOTAL ISSUE, 103,000

Mechanical Engineers' Pocket-book.

By WILLIAM KENT, A.M., M.E. 16mo, xi+1461 pages, illustrated. Morocco, $5.00 net.

A reference book of rules, tables, data, and formulæ, for the use of engineers, mechanics and students.

Deflections and Statically Indeterminate Stresses.

By CLARENCE W. HUDSON, Member, American Society of Civil Engineers, Professor of Civil Engineering, Polytechnic Institute of Brooklyn, New York, Consulting Engineer. Small 4to, xiii+258 pages, profusely illustrated with figures in the text, and full-page plates. Cloth, $3.50 net.

A sufficient number of examples have been given in this book to show how the solution of problems in deflections and statically indeterminate structure may be made on terms of the elastic properties of the materials.

Notes on Plate Girder Design.

By PROFESSOR CLARENCE W. HUDSON, Polytechnic Institute of Brooklyn, New York. 8vo, vii+75 pages, figures throughout the text, and two folding plates. Cloth, $1.50 net.

These notes have been used by the author to give his civil engineering students the theoretical and practical information necessary to enable them to make a design and general drawing for a through plate-girder railway bridge.

Fire Prevention and Fire Protection as Applied to Building Construction.

A Handbook of Theory and Practice. By JOSEPH KENDALL FREITAG, B.S., C.E., Associate Member, American Society of Civil Engineers. 16mo, viii+1038. pages, 395 figures, including line and half-tone cuts. Morocco, $4.00 net.

Presents in a manner suitable for ready reference, the present status of fire-resistance as applied to buildings.

SIXTH EDITION, Re-written and Enlarged

The Elasticity and Resistance of the Materials of Engineering.

By WILLIAM H. BURR, C.E., Professor of Civil Engineering in Columbia University in the City of New York. 8vo, 1100 pages, illustrated. Cloth, $7.50.

Sets forth the treatment of concrete steel beams and other members with complete fullness to meet the requirements of that rapidly extending field of engineering construction.

TENDERS CALLED FOR

Sealed tenders addressed to the undersigned, and endorsed "Tender for Addition and Alteration to Public Building, Lindsay, Ont.," will be received at this office until 4 p.m., on Wednesday, November 5, 1913, for the work mentioned.

Plans, specification and form of contract can be seen and forms of tender obtained at the office of Mr. Thos. Hastings, Clerk of Works, Postal Station F, Yonge Street, Toronto, at the Post Office, Lindsay, Ont., and at this Department.

Persons tendering are notified that tenders will not be considered unless made on the printed forms supplied, and signed with their actual signatures, stating their occupations and places of residence. In the case of firms, the actual signature, the nature of the occupation, and place of residence of each member of the firm must be given.

Each tender must be accompanied by an accepted cheque on a chartered bank, payable to the order of the Honorable the Minister of Public Works, equal to ten per cent. (10 per cent.) of the amount of the tender, which will be forfeited if the person tendering decline to enter into a contract when called upon to do so, or fail to complete the work contracted for. If the tender be not accepted the cheque will be returned.

The Department does not bind itself to accept the lowest or any tender.

By order,

R. C. DESROCHERS,
Secretary.

Department of Public Works,
Ottawa, October 15, 1913.

Newspapers will not be paid for this advertisement if they insert it without authority from the Department.—47381.

Sealed tenders addressed to the undersigned, and endorsed "Tender for Harbor Improvements at Port Hope, Ont.," will be received at this office until 4 p.m., on Monday, November 17, 1913, for the construction of Harbor Improvements at Port Hope, Durham County, Ontario.

Plans, specification and form of contract can be seen and forms of tender obtained at this Department and at the office of J. G. Sing, Esq., District Engineer, Confederation Life Building, Toronto, Ont., and on application to the Postmaster at Port Hope, Ont.

Persons tendering are notified that tenders will not be considered unless made on the printed forms supplied, and signed with their actual signatures, stating their occupations and places of residence. In the case of firms, the actual signature, the nature of the occupation, and place of residence of each member of the firm must be given.

Each tender must be accompanied by an accepted cheque on a chartered bank, payable to the order of the Honorable the Minister of Public Works, equal to ten per cent. (10 per cent.) of the amount of the tender, which will be forfeited if the person tendering decline to enter into a contract when called upon to do so, or fail to complete the work contracted for. If the tender be not accepted the cheque will be returned.

The Department does not bind itself to accept the lowest or any tender.

By order,

R. C. DESROCHERS,
Secretary.

Department of Public Works,
Ottawa, October 16, 1913.

Newspapers will not be paid for this advertisement if they insert it without authority from the Department.—47820.

MAIL CONTRACT.

Sealed tenders addressed to the Postmaster-General, will be received at Ottawa until noon on Friday, the 14th November, 1913, for the conveyance of his Majesty's mails, on a proposed contract for four years, six times per week each way, over Mono Road and Rural Mail Route, from the Postmaster-General's pleasure.

Printed notices containing further information as to conditions of proposed contract may be seen and blank forms of tender may be obtained at the Post Office of Mono Road, and at the office of the Post Office Inspector, Toronto.

A. SUTHERLAND,
Post Office Inspector.

Post Office Inspector's Office, Toronto, October 7th, 1913.

52 A.—2,500-26 9-12.

NOTICE TO CONTRACTORS.

TEMPORARY BRIDGE.

Sealed tenders addressed to the Board of Control will be received by the Secretary of the Board of Control, City Hall, up to 4 p.m. Tuesday, November 4th, 1913, for the erection of a temporary bridge over the Rideau River north of the present Billings Bridge.

Any tender received after the above stated time will be declared informal.

Specifications and full particulars may be obtained on application at the City Engineer's office, City Hall, Ottawa.

The Corporation does not bind itself to accept the lowest or any tender.

ARCHIBALD CURRIE,
City Engineer.

Ottawa, October 23rd, 1913.

RURAL MUNICIPALITY OF ASSINIBOIA.

NOTICE.

Sealed tenders, marked "Tenders for pavement," will be received by the undersigned up to 4 o'clock p.m., on Tuesday, the 25th day of November, 1913, for the construction of an asphalt pavement, on the north side of Portage Road, from the westerly limit of Lot 113, St. Charles, to the westerly limit of the Municipality—an approximate length of 7¼ miles—the first 1¼ miles to be 24 feet in width, and the balance 16 feet in width.

Plans and specifications may be seen at the office of the Municipal Engineer, Municipal Hall, St. Charles.

A marked cheque for 5 per cent. of the amount of tender must accompany each tender, which will be forfeited, should the successful tenderer refuse or neglect to enter into a contract, or to proceed with the work, as required in the specifications.

Tenders will also be accepted for pavements other than asphalt, in which case persons tendering must furnish plans, specifications and details of same.

The lowest or any tender not necessarily accepted.

By order of the Council.

FRANK NESS, Clerk,
Rural Municipality of Assiniboia.

Kirkfield Park P.O., Man., October 24th, 1913.

(For further Tenders see pages 84, 88 and 90.)

MEXICAN EAGLE ASPHALT

TRADE MARK

Delivered to meet the specifications of the American Society for Municipal Improvements or any other standard specifications.

Purchase MEXICAN EAGLE ASPHALT Because:

1—It is more cementitious than other asphalts.

2—Water will not readily injure it.

3—Exposure to sun and air will not cause its deterioration.

4—It has great cohesive strength.

5—It is more ductile and flexible than other asphalts.

6—Shocks will not crack it. It is very malleable.

7—We will supply asphalt having the proper penetration for your needs.

8—It is best adapted to Canada's climate—will not mark in hot weather—nor are snow or ice likely to crack it.

9—It has over 99 per cent. bitumen. Purest on the market—therefore free from deleterious matter.

10—It is so constituted that it will not be injured by the heat necessarily applied to melt it for paving operations.

Samples, prices, analyses, etc., on request.

HOISTING ENGINE and other machinery for sale: in good order. Apply to W. J. Kett, Latchford, Ont., or John Donogh, Traders Bank Building, Toronto.

PANAMA CANAL EQUIPMENT FOR SALE.—The Isthmian Canal Commission will offer for sale in the near future the equipment used in building the Panama Canal, such as rolling stock, excavating machinery, floating equipment, miscellaneous plants, and miscellaneous equipment, including locomotives, cars, steam shovels, cranes, unloaders, earth spreaders, track shifters, rock drills, well drills, dredges, barges, tugs, launches, pile drivers, concrete handling plants, pumps, rock crushers, etc. Inquiries from users of such equipment are invited for its purchase. Catalogues listing the equipment offered for sale and other information may be obtained upon application to the General Purchasing Officer, Isthmian Canal Commission, Washington, D.C. F. C. Boggs, Major, Corps of Engineers, U.S.A., General Purchasing Officer.

FOR SALE.—One model 41 Marion steam shovel, less than a year old; one Porter locomotive; ten 4-yard Western cars; one 40 H.P. boiler. Please address Box 154, *The Canadian Engineer*, Toronto.

FOR SALE.—One 35 h.p. gas engine, in good condition, suitable for city or natural gas. Apply Box 1505, General Post Office, Winnipeg.

Tenders Called For

SPECIAL NOTICE TO CONTRACTORS.

RE GREATER WINNIPEG WATER SUPPLY.

(Estimated Cost $13,500,000.)

Notice is hereby given to Contractors that tenders will be invited early in the year 1914 for the construction of works necessary for the delivery of water from Shoal Lake to the Greater Winnipeg Water District. The following is a brief description of the proposed works:—

1. A dyke and channel for the diversion of the Falcon River into Snowshoe Bay.
2. 85 miles concrete aqueduct.
3. 10 miles pipe line (probably 1916 work).
4. 900 lineal feet tunnel under Red River.
5. 85 miles of construction railway.
6. Telephone line.
7. Clearing and ditching.

The fall season of the year affords the best opportunity for inspection of proposed route of the aqueduct, and it is recommended that contractors having a view to tendering on the work should send their inspectors over the line at as early a date as possible.

Particulars as to estimated cost of the work and map of approximate location and profile of aqueduct may be obtained from the undersigned.

M. PETERSON,
Acting Secretary of the Administration Board,
Greater Winnipeg Water District.

City Hall,
Winnipeg, Canada,
October 6th, 1913.

Note.—Copy of report of the Consulting Engineers, plan and profile of work and typical details of design may be seen at the office of *The Canadian Engineer*, 62 Church Street, Toronto.

PROPOSED GOVERNMENT BUILDINGS, OTTAWA, ONT.

EXTENSION OF TIME.

Notice is hereby given that the time for the reception of designs in the first competition for the erection of Departmental and Courts Buildings, is extended for three months to Thursday, April 2nd, 1914.

By order,
R. C. DESROCHERS,
Secretary.

Department of Public Works,
—49657. Ottawa, October 23, 1913.

CANADIAN GOVERNMENT RAILWAYS.

TENDER.

Sealed tenders addressed to the undersigned and marked on the outside, "Tender, Diversion of Line, North Sydney to Leitches Creek," will be received up to and including

Monday, November 10th, 1913,

for the construction of a line of railway from North Sydney to Leitches Creek, N.S.

Plans and specification may be seen at the office of the undersigned at Ottawa, Ont., at the Station Master's Office, North Sydney, N.S., at the office of the Resident Engineer, at New Glasgow, N.S., and at the office of the Chief Engineer, Moncton, N.B., where forms of tender may be obtained.

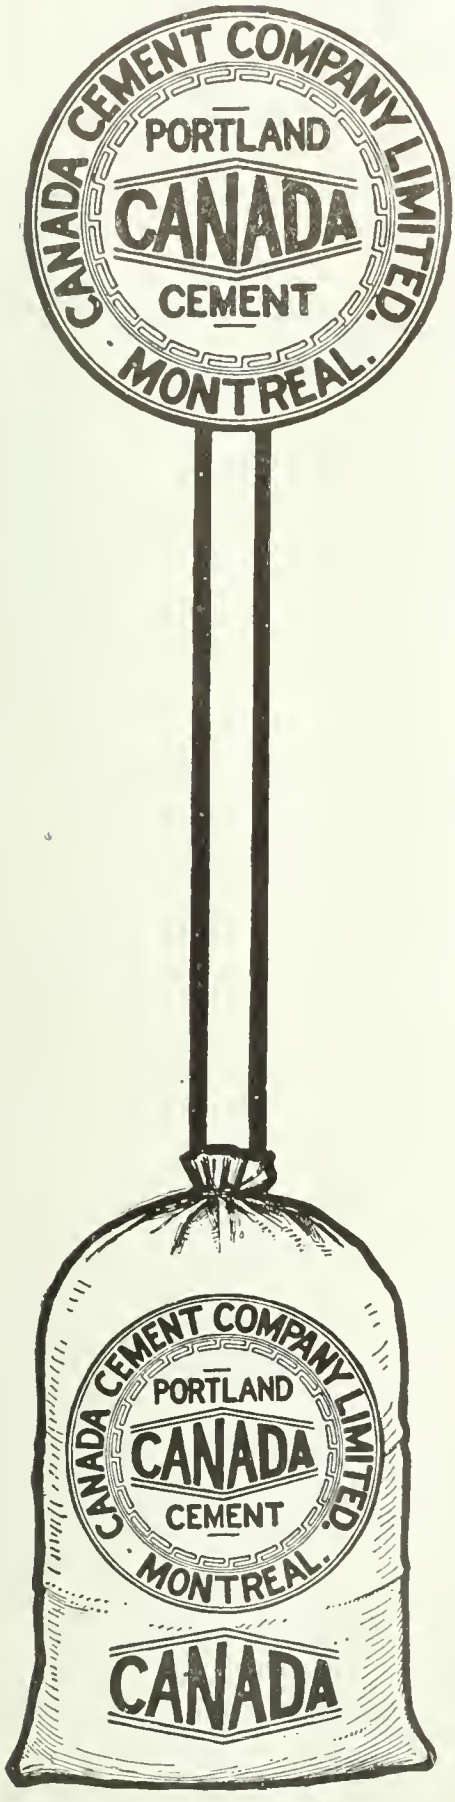
All the conditions of the specification must be complied with.

L. K. JONES,
Assistant Deputy Minister and Secretary, Department of Railways and Canals.

Ottawa, Ont., October 24th, 1913.

(For further Tenders see pages 84, 86 and 90.)

PERMANENCE—



an ideal that is now attainable

THE superiority of concrete over all other materials for the building of permanent structures is now generally admitted.

The next step towards ideal construction, is to realize that for satisfactory concrete work, it is necessary to use a cement that is uniformly high-grade

CANADA Portland CEMENT

is the selection of the leading engineers, architects and contractors. Their experience has proved that in this brand they can obtain a certainty of success.

With concrete coming into more and more general use for the construction of buildings, bridges, viaducts and highways, it is vitally important that those in authority on such matters should select the best materials obtainable.

Use the cement that our best architects and engineers have selected for their most important undertakings. Select Canada Cement — it costs no more than any others.

Positions Vacant

Advertisements under this heading two cents per word per insertion. Minimum charge fifty cents per insertion.

WANTED.—Assistant Engineers, Transitmen, Levellers, Rodmen, Chainmen, Inspectors and Draftsmen for all branches of engineering work. We make no charge to enroll you on our books. Send for application form. Civil Engineer's Employment Bureau, P.O. Box 391, Montreal.

ENGINEERING SALESMEN.—Good future offered for a few clean cut engineering salesmen, technical graduates preferred, to act as outside representatives for an established Consulting Engineering and Construction Corporation, based on co-operative plan. Main offices in Cleveland. Highest reference and financial interest required. Contract with salary, commission and expenses guaranteed. Box 172, *The Canadian Engineer*, Toronto.

Positions Wanted

Advertisements under this heading one cent per word per insertion. Minimum charge fifty cents per insertion.

AN ELECTRICAL ENGINEER; ten years' experience in Western Canada, head office, Winnipeg, is desirous of getting in touch with firms wishing Western Representative. Have managed sales office of one of the largest manufacturing concerns in Canada for the past five years, so am in close touch with conditions. 482½ Main Street, Winnipeg, Man.

CIVIL ENGINEER, 26, college graduate, 5 years' experience in surveying, reinforced concrete structures, and waterworks, field and office, desires position. Familiar with water power investigations. Excellent references, thoroughness. Box 170, *The Canadian Engineer*, Toronto.

MECHANICAL DRAFTSMAN.—Young man with technical education, including steam power plant design, with shop and office experience, desires position with engineers, who design steam and hydro-electric power plants. Location preferably in Ontario or Quebec. Is employed in Montreal. Box 160, *The Canadian Engineer*, Toronto.

STENOGRAPHER.—Experienced in engineering correspondence, estimating and accounting, desires position, preferably as secretary. Gilt-edged references. Please address, Box 168, *The Canadian Engineer*, Toronto.

Condensed Advts.

Advertisements under this heading three cents per word per insertion. Minimum charge fifty cents per insertion.

FOUNDRY AND SHOP WANTED.—United States manufacturer desires to lease Canadian foundry and machine shop. Please give full particulars of equipment and state terms desired. All letters confidential. Address Box 156, *The Canadian Engineer*, Toronto.

FOR SALE.—Old-established and well-known Canadian engineering company, doing large business from coast to coast—an excellent opportunity for investors or for anyone wishing to extend operations in Canada by taking over a going concern, with complete plant staff and extensive connection. All communications strictly confidential. Address Box 164, *The Canadian Engineer*, Toronto.

Tenders Called For

(Continued from page 88.)

TENDERS FOR 84-IN. STEEL CONDUIT.

Tenders will be received by registered post only, addressed to the Chairman of the Board of Control, City Hall, Toronto, Canada, up to noon on

Tuesday, November 18th, 1913,

for the supplying and laying of an 84-inch steel conduit from the Pure Water Reservoir on Toronto Island to the South Tunnel Shaft.

Specifications and tender forms may be obtained upon application at the Department of Works, Room 10, City Hall, Toronto.

Envelopes containing tenders must be plainly marked on the outside as to contents. Conditions relating to tendering, as prescribed by city by-law, must be strictly complied with, or the tenders may be declared informal. Tenderers shall submit with their tenders the names of two personal sureties approved by the City Treasurer, or in lieu thereof, the bond of a guarantee company, approved as aforesaid.

The lowest or any tender not necessarily accepted.

H. C. HOCKEN (Mayor),
Chairman, Board of Control.

City Hall, Toronto, October 17, 1913.

(For further Tenders see pages 84, 86 and 88.)

TRADE ENQUIRIES.

The following were among the inquiries relating to Canadian trade received at the office of the High Commissioner for Canada, 17, Victoria Street, London, S.W.:—A firm at Newcastle-on-Tyne, desire the addresses of Canadian exporters of asbestos.

From the branch for City trade inquiries, 73 Basinghall Street, E.C.:—A Sheffield company, manufacturing tool, alloy and mining drill steel, also certain tools, saws, etc., would like to secure the services of some first-class firm, preferably in Winnipeg, to act as their representatives for Western Canada.

MONTREAL MARKET LETTER

Montreal, October 27th.

The local iron and steel trade is a little demoralized by the uncertainty of outside markets. During the past few weeks advices have been received both from the United States and from abroad to the effect that the price of steel products have declined all the way round. This has affected the local market and as a consequence prices of certain products, such as, bar iron and steel plates and pig-iron, are all lower than they were a week ago. Pig-iron is attracting considerable attention. There has been a fair amount of activity of late, but large contracts are withheld and it is likely that the bulk of the orders placed recently have been brought out very largely by the knowledge that freight rates will advance in the course of a very few weeks, and in order to take advantage of the low freights the goods must be shipped ere a great length of time. Prices have been marked down on a number of products as will be seen from the following list:—

Black Steel Plates.—¼-inch, $2.30 per 100 lbs.; 3-16-inch, $2.60 per 100 lbs.; 10-gauge, $2.70 per 100 lbs.; 12-gauge, $2.75 per 100 lbs.; 14-gauge, $2.50 per 100 lbs.; 16-gauge, $2.50 per 100 lbs.; 18-gauge, $2.60 per 100 lbs.; 20-gauge, $2.60 per 100 lbs.; 22-24-gauge, $2.70 per 100 lbs.; 26-28-gauge, $2.80 per 100 lbs.

BRITISH COLUMBIA—Pacific Lock Joint Pipe Co., 1005 A St., Tacoma, Wash.; Globe Bldg., Seattle, Wash.

MARKET CONDITIONS

Montreal, October 25th, 1913.

Bar Iron and Steel—Trade is reported active. Bar iron, $2.05 per 100 pounds; best refined horseshoe, $2.30; forged iron $2.20; mild steel, $2.15; sleigh shoe steel, $2.15 for 1 x ⅜ base; tire steel, $2.25 for 1 x ⅜ base; toe caulk steel $3; machine steel, iron finish, $2.25.

Cement—Canadian cement is quotable, as follows, in car lots, f.o.b., Montreal:—$1.35 to $1.40 per 350-lb. bbl., in cotton bags, adding 10c. for each bag. Good bags re purchased at 10c. each. Paper bags cost 2½ cents extra, or 10c. per bbl. weight.

Chain—The market is quoted per 100 lbs. as follows:—¼-in., $5.65; 5/16-in. $4.70; ⅜-in., $4.00; 7/16-in., $3.65; ½-in., $3.45; 9/16-in., $3.45; ⅝-in., $3.35; ¾-in., $3.25; ⅞-in., $3.15; 1-in., $3.05.

Explosives and Accessories—Dynamite, 50-lb. cases, 40 per cent. proof, 15c. in single case lots, Montreal; 50 per cent., 16½c., and 60 per cent., 18c. Blasting powder, 25-lb. kegs, A, $1.85, and B, $2.35 per keg. Special quotations on large lots of dynamite and powder. Detonator caps, case lots, containing 5,000, 75c. per 100; double strength, $1, and broken lots higher; electric blasting apparatus:—Batteries, 1 to 10 holes, $13.50; 1 to 10 holes, $20.50; 1 to 50 holes, $41. Wire, leading, 1c. per foot; connecting, 50c. per lb. Fuses, platinum, single strength, per 100 fuses:—4-ft. wires, $3; double strength, $3.50; 6-ft. wires, $3.54, and double, $4.01; 8-ft. wires, $4.08, and double, $4.58; 10-ft. wires, $5, and double, $5.12.

Galvanized Iron—The market is steady. Prices, basis, 28-gauge, are:—Queen's Head, $4.40; Colborne Crown, $4.20; Apollo, 10¼ oz., $4.30. Add 25c. per 100 lbs. to above figures for less than case lots; 26-gauge is 25c. less than 28-gauge, American 28-gauge and English 26 are equivalents, as are American 10¾ oz., and English 28-gauge.

Galvanized Pipe—(See Pipe, Wrought and Galvanized)

Iron.—Following prices are on dock. No. 1 Summerlee, $21.75 per ton; selected Summerlee, $21.25; soft Summerlee, $20.75 per ton. No. 3 Middlesboro irons are about $19 per ton. Carron iron number for number and grade for grade is quoted about the same price as Summerlee. Canadian iron sells here at about $19 to $19.50 per ton, on track.

Lath—See Lumber, etc.

Lumber, etc.—Prices on lumber are for car lots, to contractors, at mill points. Red pine, mill culls out, $20 to $22 per 1,000 feet; white pine, mill culls, $20. Spruce, 1-in. by 4-in. to 6-in., $21; 1 x 7 to 9, $24 per 1,000 ft.; mill culls, $18. Hemlock log run, culls out, $19. Railway Ties, Standard Railway Ties, hemlock or cedar, 50 to 55c. each. Telegraph poles: seven-inch top, cedar poles, 25-ft. poles, $2, each; 30 ft., $3.75; 35-ft., $4.50 each; 40-ft., $6; 45 to 50, 16c. per foot. Laths: Quotations per 1,000 laths, at manufacturers' points. Spruce 4-ft. x 1½ in., mill run, $3 to $3.25; pine, 4-ft. x 1⅜-in., mill run, $3.25 to $3.75. Shingles: Cedar shingles, same conditions as laths, X, $2.10; XX, $2.40; XXX, $2.80.

Pipe—Cast Iron—The market is dull and rather easy:—$34 for 6 and 8-inch pipe and larger; $35 for 40-inch at the foundry. Pipe, specials, $3 per 100 pounds. Gas pipe is quoted at about $1 more than the above.

Pipe—Wrought and Galvanized—Demand is fair and the market steady: —¼-inch $5.50, with 63 per cent. off for black, and 48 per cent. off for galvanized; ⅜-inch, $5.50, with 63 per cent. off for black, and 48 per cent. off for galvanized; ½-inch, $8.50, with 69 per cent. off for black, and 59 per cent. off for galvanized. The discount on the following is 72½ per cent. off for black, and 62½ per cent. off for galvanized; ¾-inch, $11.50; 1-inch, $16.50; 1¼-inch, $22.50; 1½-inch, $27. On the following the discount is 72½ per cent. for black and 62½ per cent. for galvanized:—2-inch, $36; 2½-inch, $57.50, and 3-inch $75.50; 72½ per cent. off for black, and 62½ per cent. off for galvanized: 3½-inch $95 4-inch, $1.08.

Toronto, October 29th, 1913.

The following are the wholesale prices for Toronto, where not otherwise explained, although for broken quantities higher prices are quoted:

Axes.—Standard makes, double bitted, $6 to $10; single bitted, per dozen, $7.50 to $9.

Bar Iron—$2.25 base, per 100 lbs., from stock to wholesale dealer. In enormous demand.

Bar Mild Steel—Per 100 lbs., $2.25. Sleigh shoe and other take same relative advance.

Boiler Plates—½-inch and heavier, $2.20. Boiler heads 25c. per 100 pounds advance on plate. Tank plate, 3-16-inch, $2.40 per 100 pounds.

Boiler Tubes—Orders continue active. Lap-welded, steel, 1¾-inch, 10c. 1½-inch, 9c. per 10-ft.; 2-inch, $8.50 to $9; 2¼-inch, $10; 2½-inch, $10.50; 3-inch, $12.10; 3½-inch, $15; 4-inch, $19.

Bricks—In active movement. The price is $11.50 for grey stock, $12 for red stock. Don Valley pressed brick are in request. No. 1 dry pressed and buff bricks are worth $18 delivered and $17 at works per 1,000. Port Credit Brick Company's prices are as follows, f.o.b., Port Credit: Wire cut bricks, $10 per M.; pressed bricks, $14 to $15 per M., three grades.

Broken Stone—Lime stone, good hard, for roadways or concrete, f.o.b., quarries 70 to 75c. per ton of 2,000 lbs., either 1-inch, 10c., 2-inch, or larger, price all the same. Rubble stone, 55c. per ton, Schaw station, and a good deal moving. Broken granite is selling at $3 per ton for gond Oshawa, or Quebec Province. At Washago, $2.50 per ton for small, and $1.15 for large, freight to Toronto 60 cents.

Cement—Demand very brisk, and prices maintained. In large quantities the price is $1.50, sacks, 40c. extra; car lots $1.55, sacks extra; city dealers ask $1.85, sacks extra. Prices remain firm.

Copper Ingot—The market is lower at 15½ to 16c., sheet copper case (16 oz. soft), 22½c. to 24½c. per lb.

Detonator Caps—75c. and $1 per 100; case lots, 5,000, 20 per cent. off.

Dynamite—The prices for this explosive vary according to the percentage of nitro-glycerine compounded in the mixture and are as follows, f.o.b., Toronto:—40 per cent., 16¼ cents per pound, 1 to 9-case lots, 50 lbs. to case. For each additional 10 per cent. nitro-glycerine add 1½c. per hundred. For 10-case lots and over deduct ½ cent. For 20-case lots and over deduct 1 cent. For 40-case lots and over deduct 1½ cents.

Fuses—Electric Blasting—Double strength, $3.50 per hundred, advance 54c. per hundred for each 2-in. wire additional. Single strength, $3 per hundred, advance 54c. per hundred for each 2-in. wire additional.

Iron Chain—¼-inch, $5.75; 5-16-inch, $5.15; ¾-inch, $4.15; 7-16-inch, $3.95; ½-inch, $3.75; 9-16-inch, $3.70; 5-8-inch, $3.55; ¾-inch, $3.45; ⅞-inch, $3.40; 1-inch, $3.40 per 100 lbs.

Iron Pipe—Quotations are changed as follows:—Black pipe, ¼-inch, $2.04; ⅜-inch, $2.04; ½-inch, $2.72; ¾-inch, $3.16; 1-inch, $4.54; 1¼-inch, $6.19; 1½-inch, $7.43; 2-inch, $9.90; 2½-inch, $15.80; 3-inch, $20.75; 3½-inch, $26.13; 4-inch, $29.70; 5-inch, $40.60; 6-inch, $52.64. Galvanized Pipe, ¼-inch, $2.86; ⅜-inch, $2.86; ½-inch, $3.57; ¾-inch, $4.31; 1-inch, $6.19; 1¼-inch, $8.44; 1½-inch, $10.13; 2-inch, $13.50; 2½-inch, $21.56; 3-inch, $28.31.

Lead—Firmer, $5.25 to $5.50.

Pig Iron—We quote Clarence at $24 for No. 3; Cleveland, $24; Summerlee, $27; Hamilton quotes $22; Midland, No. 1, $22; No. 2, $21.50. There is considerable enquiry for 1912.

Pitch and Tar—Pitch, unchanged at 75c. per 100 lbs. Coal tar, $3.75 per barrel.

Roofing Slate—Most of the slate used in Canada comes from Pennsylvania or Maine, the Canadian supply being slender and mostly from the Rockland quarries of the Eastern Townships, in Quebec. There is a great variety of sizes and qualities, so that it is difficult to indicate prices. But Jackson Bangor, 10 x 16 may be quoted at $6.75 per square of 100 square feet f.o.b. cars, Toronto; seconds, 50c. less. Mottled, $8; green $8, with a prospect of advance. Dealers are fairly busy.

Sand—Sharp, for cement or brick work, $1.15 per net yard f.o.b., cars, Toronto siding.

Sewer Pipe—

	4-in.	6-in.	9-in.	12-in.	24-in.
Straight pipe; per foot	$0 25	$0.40	$0.65	$1.00	$ 3.25
Single junction, 1 or 2 ft. long	1.00	1.60	2.60	4.00	13.00
Double junctions	1.25	2.00	3.25	5.00	16.25
Increasers and reducers	....	1.60	2.60	4.00	13.00
P. & H. H. traps	2.00	3.20	6.50	15.00	....
Bends	0.75	1.20	1.95	3.00	9.75

Above is the October list as changed. The retail price is less 65 per cent. off these figures on all sizes 9 inches and under, or less 60 per cent. off these figures on anything over 9 inches. For car-loads a greater discount.

Steel Beams and Channels—Active—We quote:—$2.65 to $3 cut to length per 100 lbs., according to size and quantity; angles, 1½ by 3-16 and larger, $2.50 to $2.75; tees, $2.75 to $3 per 100 lbs. Extra for smaller sizes of angles and tees.

Sheet Copper—22c. per lb.

Sheet Steel—American Bessemer, 10-gauge, $2.75; 12-gauge, $2.80; 14-gauge, $2.50; 17, 18, and 20-gauge, $2.75; 22 and 24-gauge, $2.80; 26-gauge, $2.85; 28-gauge, $3. A very active movement is reported at unchanged prices.

Sheets, Galvanized—Apollo Brand—Sheets, 6 or 8 feet long, 30 or 36 inches wide; 10-gauge, $3; 12-14-gauge, $3; 16, 18, 20, $3.30; 22-24, $3.40; 26, $3.50; 28, $3.90; 29, $4.10; 10¾, $4.10 per 100 lbs. Fleur de Lis—28-gauge, $4.25; 26, $4.05 per 100 lbs. Active and firm at these prices.

Tin—The combination seems to hold, and the price, 45 to 50c., lower.

Tool Steel—Jowett's special pink label, 10½c. Cammel-Laird, 16c "H.R.D." high speed tool steel, 65c.

Tank Plates—3-16 inch, $2.40 per 100 lbs.

Zinc—Spelter—Good demand, and the feeling strong. Light stock; excellent demand. We quote very firm at $6 to $6.50 per cwt.

Winnipeg, October 28th, 1913.

Anvils—Per pound, 11½ to 12½c.; Buckworth anvils, 80 lbs. and up, 10¾ to 10¾c., anvil and vise combined, each $5.50.

Bar Iron—$2.50 base.

Bars—Crow, $4.50 per 100 pounds.

Beams and Channels—$3 to $3.10 per 100 up to 15-inch, 4, 30, 41, 50, 118, 119, 172, 132, 145, 176.

Brick—Kiln run per M, $13; sewer pipe per M, $14; chimney per M, $14; veneer per M, $15; pressed per M, $25 to $50; enameled per M, $100; sand lime per M, $13.

Cement, Portland—$2.40 to $2.50 per barrel.

Chain—Coil, 3-16-in., $10; ¼, $7.25; 5-16, $5.85; ⅜, $5; 7.16, $4.75; ½, $4.50; 9-16, $4.50; ⅝, $4.40; ¾, $4.25. Logging, 5-16, 6½c.; ⅜, 5¾c. Tie out, 70 and 10 pe cent.

Copper—Tinned, boiler, 26½c., planished, 29½c.; boiler and T. K. nits, plain, tinned, 45 per cent. discount.

Dynamite—$11 to $13 per case.

Galvanized Iron—Apollo, 10¾, $4.80; 28, $4.60; 26, $4.20; 22, $4.10; 24, $4.10; 20, $4; 18, $3.95; 16, $3.90. Queen's Head, 28, $4.90; 26, $4.70; 24, $4.30; 22, $4.30; 20, $4.10 per cw

Iron—Swedish iron, 100 lbs., $4.75 base; sheet, black, 14 to 22 gauge, $3.75; 24-gauge, $3.90; 26-gauge, $4; 28-gauge, $4.10. Galvanized—American, 18 to 20-gauge, $4.40; 22 to 24-gauge, $4.65; 26 gauge, $4.65; 28-gauge, $4.90; 30-gauge, $5.15 per 100 lbs. Queen's Head, 22 to 24-gauge, $4.65; 26-gauge English, or 30-gauge American, $4.90; 30-gauge American $5.15. Fleur de Lis, 22 to 24-gauge, $4.50; 28-gauge American, $4.75; 30-gauge American, $5; bar, $2.50 base.

Pipe—Iron, black, per 100 feet, ¼-inch, $2.40; ⅜-inch, $2.55; ½-inch, $3.35; ¾-inch, $4; 1-inch, $5.75; 1¼-inch, $7 80; 1½-inch, $9.35, 2-inch, $12.50; galvanized—½-inch $4.35; ¾-inch, $5.20; 1-inch, $7.55; 1¼-inch, $10.25; 1½-inch, $12.25; 2-inch, $16.40. Lead, 7.60 per cent., full coil.

Pitch—Pine, $6.50 per barrel, in less than barrel lots, 4c. per lb.; roofing pitch, $1 pe· cwt.

Steel Plates, Rolled—3-16-in., $3.35 base; machinery, $3 base; share, $4.50 base; share crucible, $5.50; cast share steel, $7.50; toe caulk, $4.50 base tire steel, $3 base; cast tool steel, lb., 9 to 12½c.

Tool Steel—8½ to 15c. per pound.

HANDLING MATERIALS BY BUCKET CARRIERS

THE "ONE-PIECE" SYSTEM FOR ELEVATING AND CONVEYING TYPES, CAPACITIES, ECONOMIC SPEEDS, HORSE-POWERS—ADVANTAGES AND DISADVANTAGES*

By REGINALD TRAUTSCHOLD, M.E.,
Consulting Engineer, New York City.

ALL conveying and elevating apparatus so far discussed has had one and the same limitation; that is, each particular type of equipment has been destined for practically but one operation, either that of conveying in a more or less horizontal plane or else elevating more or less vertically. From a purely economic standpoint such limitation is actually an advantage, for the use of a separate and distinct equipment for each main operation is frequently advisable, particularly in installations where the various operations of conveying and elevating must of necessity be continuous. A breakdown in an elevator or conveyer would then not necessarily mean a shutdown, for some temporary makeshift—possibly manual handling of the load—could be resorted to for carrying past the damaged conveyer or elevator and the balance of the operations performed as ordinarily. However, one apparatus for performing both operations of elevating and conveying has the advantage of simplicity and, though a breakdown anywhere in such equipment must necessarily mean a complete shutdown of the entire conveying and elevating system while repairs are made, this more flexible outfit is frequently installed in preference to the more reliable but more complex systems in which the various main operations are performed by individual apparatus. The "one-piece" system frequently possesses the advantage of lower initial cost, and further, the advantage that material may be carried in either direction. For elevating, the "one-piece" system necessitates a succession of buckets, somewhat similar to those of the bucket elevator, and the conveying operations must necessarily be performed by the same buckets. The apparatus is commonly designated as a "bucket carrier," both to distinguish it from a bucket elevator and because such equipment can be, and is sometimes, used to carry material only in a horizontal plane or in an inclined plane.

Classification and Construction.—Two distinct types of bucket carriers are in general use—those in which the buckets are rigidly attached to the endless carrying chains so that on horizontal stretches the buckets act as do the flights of flight conveyers and drag the load along a trough; and those in which the buckets are suspended from the carrying chains so that they maintain an upright position in whatever plane they may be advancing. The latter type of bucket carriers, those with pivoted buckets, require discharging devices which tip the buckets so that their load may be discharged at a specified point. This limits the distributing capability of the pivoted bucket carrier, for but one discharge point is all that is possible without greatly complicating the equipment—that is, only one discharge point without shifting the discharging, bucket tipping, device. The annoyance and inconvenience of frequently shifting the discharging device may be somewhat reduced by the installation of systems of distributing chutes, etc. The pivoted bucket construction also complicates the loading of the carriers to some extent, as they are nearly invariably loaded on a horizontal stretch of carrier, in order to avoid the necessity and complication of a receiving receptacle similar to an elevator boot employed for bucket elevators. The carrier's buckets must then be proportioned so that, on horizontal stretches, there may be no gaps between buckets—only possible when the buckets are provided with lips that extend from one bucket over the edge of the succeeding bucket—or else the bucket carrier must be provided with a reciprocating feeder that delivers load to the carrier only when the succeeding buckets are each in the proper position for receiving their load. Rigid bucket carriers, on the other hand, may be loaded as steadily and uniformly as a flight conveyer.

The construction of bucket carriers permits them to run in almost any conceivable path provided the buckets always lie in the same vertical plane. That is, the elevation of the bucket carrier path may be rectangular, a series of steps with the return run of buckets in a series of descending steps or, as is more common, with the buckets brought down vertically from the end of the carrier travel in the first general direction to the plane of the loading point and thence in a more or less horizontal path to the point where the general direction of advance is upward, etc., etc. Bucket carriers traveling in rectangular paths are the more common and are also the more convenient in that one load can be elevated and then carried horizontally to the desired discharge point while a second load can be carried over the lower horizontal run, elevated and discharged where desired. This type of carrier is frequently installed in power houses where coal is elevated and discharged to coal bunkers by the forward run of buckets and the return run of buckets is employed to carry the ashes from under the grates and discharge to an elevated ash bin from which they may be subsequently removed by other means.

Bucket carriers can, of course, be equipped with buckets of almost any conceivable size and shape, but practice has standardized a rectangular shape with a

*This article is the *fifth* of a series written for *The Canadian Engineer* by Mr. TRAUTSCHOLD on the mechanical handling of materials.

depth about equal to the width. Such buckets are referred to in terms of length and width of bucket, so that the carrying capacity of any standard bucket carrier, loaded with any given material, is dependent upon the spacing of the buckets and the speed at which the carrier is run. Table XI. gives the average carrying capacity of certain common sizes of bucket carriers (length of bucket times in width) when handling material weighing 100 pounds per cubic foot at a carrier speed of 50 feet per minute. At equal spacing of buckets, the carrying capacity of bucket carriers handling other material at other speeds is directly proportional to both weight of material carried and speed of carrier. These definite relations and the fact that all standard buckets are similarly proportioned, permits the expression of the carrying capacity of any standard bucket carrier in the form of a convenient equation. (See Formula XXI.).

Table XI.—Capacity of Bucket Carriers in Tons Per Hour. Material Weighing 100 Pounds Per Cubic Foot. Carrier Speed, 50 Feet Per Minute.

Capacity: $W = \frac{0.00535 \times w^2 \times l \times w'}{S''}$ Formula XXI.

Where:
- W = Capacity in tons per hour.
- w = Width of bucket in inches.
- l = Length of bucket in inches,
- w′ = Weight of material handled in lbs. per cu. ft.
- S″ = Spacing of buckets in inches.

Though the average speed of a bucket carrier is about 50 feet per minute, all materials are not most economically carried at that speed. Certain materials permit considerably higher speeds, while others must be handled more slowly, or excessive breakage, etc., is apt to occur. Table XII. gives speeds that have been found to be economic for certain of the common materials usually handled by such equipment. These speeds are by no means fixed, however, and considerable variation is permissible and not infrequently advisable. In fact, some authorities recommend quite different speeds for some of the materials mentioned in Table XII. However, the data of this table has been collected from numerous efficient installations of bucket carriers and may safely be used as a basis of operation.

Table XII.—Economic Speeds of Bucket Carriers for Various Materials.

Material	Advisable Speed
Coke	40 feet per minute
Broken Stone (coarse); Lump Coal—R.M.	50 feet per minute
Ashes, Lime and Cement	60 feet per minute
Ore, Crushed Stone, Sand and Gravel	70 feet per minute
Fine Coal	80 feet per minute

The consumption of power by the rigid bucket and by the pivoted bucket types of bucket carriers naturally differs considerably, but the difference is somewhat equalized by the fact that the pivoted bucket type is nearly invariably furnished with a reciprocating feeder that consumes quite appreciable power. Other than for this special feature of the pivoted bucket carrier, three distinct operations consume power whether the carrier is of the rigid bucket or pivoted bucket construction: 1st, the running of the apparatus itself, which depends upon the total weight of the moving parts—the weight of the endless chains, the buckets and the attachments; 2nd, the carrying of the load horizontally; and 3rd, the operation of elevating the load. Although load may be carried in two general directions by a bucket carrier, such double transfer of load is seldom, if ever, accomplished at the same time, so that it is customary to figure an allowance of power for conveying in one direction only. The elevating operations consume only about the theoretical power required for the load, as the descending buckets and chains compensate for the work of raising these parts and the friction and other unavoidable losses are almost independent of the height of lift, so are allowed for in the power provisions for horizontal travel of load. Standardization of equipment permits the expression of the weight of the moving parts of the carrier in terms of its carrying capacity in tons per hour, for the strength, hence the weight of the chains, attachments and buckets vary very closely with the load that the carrier is capable of handling. In the derivation of Formulæ XXII. and XXII-a, the value of all constants are based on actual results obtained in a number of successful and economic installations of such equipment and, though the results given by such formulæ may be somewhat higher than the claims advanced by certain manufacturers of bucket carriers, dependence upon the use of formulæ for deriving horsepower requirements of bucket carriers that give smaller results is inadvisable, for so many conditions really effect the question of power consumption by such equipment that no theoretical equation can be derived that will fit all cases.

Horsepower:—

- W = Weight of load handled in tons per hour.
- L = Length (total) of horizontal stretches of Carrier in one general direction in feet.
- H = Height (total) or distance through which load is elevated in feet.
- V = Velocity (speed) of Carrier in feet per minute.
- W_c = Weight of moving parts of Carrier in lbs. per foot.
  - = 0.608 W—Carriers with rigid buckets.
  - = 0.756 W—Carriers with pivoted buckets.
- W′ = Weight of load handled in lbs. per minute.
  - = 33 W

$\frac{W'}{V} = \frac{33\ W}{V}$ = weight of load handled in lbs. per minute per foot.

- f_s = Speed factor = 0.18 —Carriers with rigid buckets.
  - = 0.035—Carriers with pivoted buckets.
- f_l = load factor = 0.70—Carriers with rigid buckets.
  - = 0.20—Carriers with pivoted buckets.

Horsepower required to run empty carrier:—

Carriers with rigid buckets.

Total weight of moving parts = $2(H + L)W_c$
Average velocity of Carrier (V) = 50 feet per minute.

$$HP = \frac{2(H + L)W_c \times V \times f_s}{33000} = \frac{2(H + L) \times 0.608\ W \times 50 \times 0.18}{33000}$$

$$= \frac{33\ (H + L)W}{100{,}000}$$

Carriers with pivoted buckets.

Total weight of moving parts = $2(H + L)W_c$
Average velocity of Carrier (V) = 50 feet per minute.

$$HP = \frac{2(H + L)W_c \times V \times f_s}{33000} = \frac{2(H + L) \times 0.756\ W \times 50 \times 0.35}{33000}$$

$$= \frac{8(H + L)W}{100000}$$

Horsepower required for handling load on horizontal travel:—

Carriers with rigid buckets.

$$HP = \frac{W' \times f_1 \times V \times L}{33000 \times V} = \frac{33\ W \times 0.70 \times L}{33000} = \frac{70\ WL}{100{,}000}$$

Carriers with pivoted buckets.

$$HP = \frac{W' \times f_1 \times V \times L}{33000 \times V} = \frac{33\ W \times 0.20 \times L}{33000} = \frac{20\ WL}{100{,}000}$$

Horsepower required for elevating load:

All types of Bucket Carriers.

$$HP = \frac{33\ W \times H \times V}{33000 \times V} = \frac{100\ WH}{100{,}000}$$

Horsepower required for Reciprocating Feeder:—

Carriers with pivoted buckets only.

$$HP = \frac{9\ W}{100} \text{ (from experiment).}$$

Total horsepower required:—

Carriers with rigid buckets.

$$HP = \frac{(103\ L + 133\ H)W}{100000}$$ Formula XXII.

Carriers with pivoted buckets

$$HP = \frac{(28\ L + 108\ H)W}{100000} + \frac{9\ W}{100}$$ Formula XXII-a

The average bucket carrier is now pretty well standardized as to cost as well as in design, so that unless the buckets are of abnormal proportions or very complicated in design and the carrier chains are efficiently economical such a close relationship exists between the cost of the component parts of such a system and its size and length that an equation may be derived that will closely approximate the cost of any ordinary installation. As far as cost is concerned, the component parts naturally fall into four general groups: 1st, the chains which depend upon the total length of the bucket carrier and the weight of the load to be carried; 2nd, the buckets and attachments which also depend upon the total length of the carrier and the weight of the load; 3rd, the trough, gates, etc., for carriers with rigid buckets, or the rails, discharging devices, etc., for carriers with pivoted buckets, all of which depend upon the size of the buckets and the horizontal travel of the carrier in one direction; and 4th, the sprockets, drive, etc., which depend upon the size of the buckets, or size of carrier—to which must be added the cost of the reciprocating feeder for bucket carriers with pivoted buckets, which latter varies directly in cost with the square root of the product of the width and length of the buckets. As the weight of the load to be carried depends upon the size of the buckets and their spacing, it is possible to derive an equation for ascertaining the approximate cost of any system in which the variable factors are those of total length of bucket carrier, size of bucket and weight of material to be handled. Such an equation follows as Formulæ XXIII. and XXIII.-a, the results attained from the use of which will give very close approximations of the cost of any average standard type of bucket carrier equipment, including an allowance sufficient to cover the cost of a simple installation.

Initial Cost:—

C = Cost of Bucket Carrier equipment in dollars.
wl = Size of buckets in square inches = width x length.
H = Height (total) to which load is elevated in feet.
L = Horizontal travel (total) of buckets in one direction in feet.
S = Spacing of buckets in inches.
w' = Weight of material to be handled in lbs. per cubic foot.

Carriers with rigid buckets.

Average cost of chains $\dots\dots \frac{0.024\ wl(H + L)}{S} \times w'$

buckets $\dots\dots \frac{0.026\ wl(H + L)}{S} \times w'$

Average cost of trough, gates, etc. $\dots\dots 0.005\ wl\ L$

sprockets, drive, etc. $\dots\dots 15.25\ \sqrt{wl}$

$$C = \frac{0.05\ wl(H + L)}{S} \times w' + 0.005\ wl\ L + 15.25\ \sqrt{wl}$$ Formula XXIII.

Carriers with pivoted buckets.

Average cost of chains $\dots\dots \frac{0.025\ wl(H + L)}{S} \times w'$

buckets $\dots\dots \frac{0.045\ wl(H + L)}{S} \times w'$

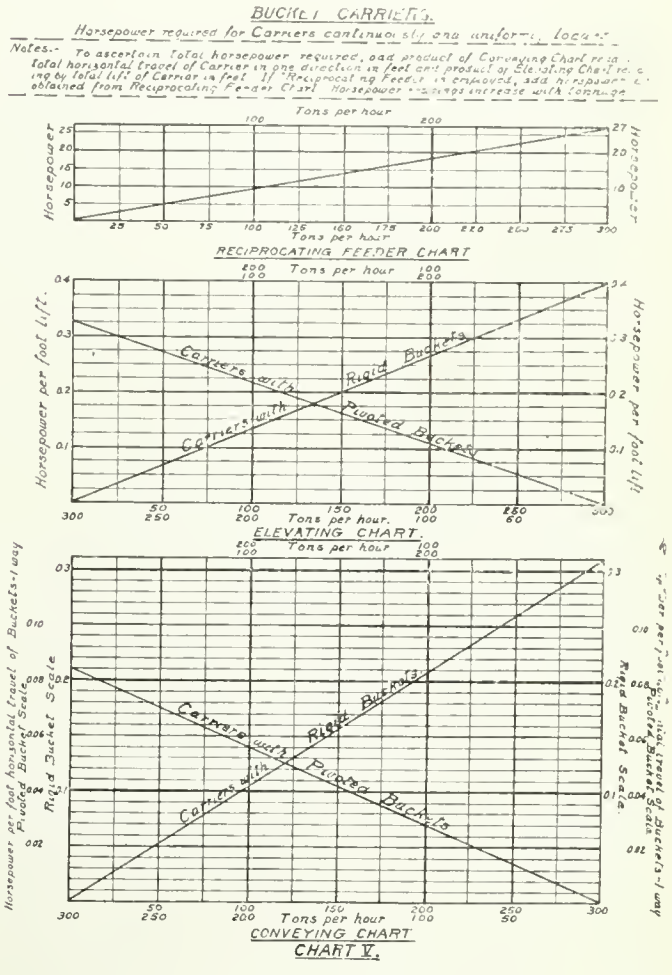
rails, discharging device, etc. $0.05\ \sqrt{wl}\ L$

sprockets, drive, etc. $\dots\dots 15.25\ \sqrt{wl}$

reciprocating feeder $\dots\dots 0.75\ \sqrt{wl}$

$$C = \frac{0.07\ wl(H + L)}{S} \times w' + 0.05\ \sqrt{wl}\ L + 16\ \sqrt{wl}$$ Formula XXIII-a.

The close relationship that exists between the carrying capacity of a bucket carrier and the size of its buckets (spacing of buckets depending almost entirely



BUCKET CARRIERS.
Horsepower required for Carriers continuously and uniformly loaded.
Notes:- To ascertain total horsepower required, add product of Conveying Chart reading by total horizontal travel of Carrier in one direction in feet and product of Elevating Chart reading by total lift of Carrier in feet. If Reciprocating Feeder is employed, add horsepower obtained from Reciprocating Feeder Chart. Horsepower increases directly with tonnage.

upon their size and hence not varying greatly comparatively) allows the expression of cost of equipment in terms of tonnage handled (capacity) suitable for use when considering the factors that enter into the net operating cost. An error enters the initial cost of equipment as

ascertained by such means, because the initial cost of an equipment for handling material of any given weight does not really vary directly with the weight, although it does increase somewhat as the weight of the material to be handled increases, but this error is greatly discounted by the comparatively small proportions of the initial cost of equipment that actually enters into the question of net operating cost, being in fact only the fixed charges represented by interest on investment, taxes, insurance, etc. Depreciation, on the other hand, usually increases more rapidly than the increase in initial cost apparent when handling heavier materials, so that, being figured as a percentage of the initial cost, the inaccuracy of figuring a fixed rate of depreciation is compensated for by unduly high initial cost upon which it is figured. Power costs entering into net operating cost are, of course, directly dependent upon the tonnage handled, so that no error is apparent that is due to the high initial cost as expressed in terms of tonnage the carrier is capable of handling. In fact, the only error that appears at all is in figuring the fixed burden of interest, etc., which is but a relatively small percentage of the total net operating cost. Hence, Formulæ XXIV. and XXIV.-a, expressing the net operating cost of handling a ton of material over any bucket carrier system, may be considered conservatively accurate. More accurate results would be unattainable without most careful and complicated bookkeeping—far more systematic and painstaking than is practiced in any indsutrial undertaking or power house—so that the use of Formulæ XXIV. and XXIV.-a should prove of considerable value to the present operator of such a system of mechanical material handling as well as aiding his or others in forming an opinion as to the advisability of any contemplated bucket carrier installation, such formulæ giving the true economic value of the layout.

Net Operating Cost (N.O.C.):—

W = Weight of load handled in tons per hour.
L = Length (total) of horizontal travel of Carrier in one general direction in feet.
H = Height (total) or distance through which load is elevated in feet.

Carriers with rigid buckets.

Average cost of chain .....0.2420 W(H + L)
buckets .....0.2621 W(H + L)
trough, gates, etc. .....0.03 WL.
sprockets, drive, etc. .....5.5 W
Total average cost = 0.5041 W(H + L) + 0.03 WL + 5.5 W

Fixed charges:—
Interest .. 6% total cost
Insurance.. 1%
Taxes .... 2%—¾ cost
= 0.04286 W(H + L) + 0.0255 WL + 0.4675 W

Depreciation, renewals, repairs, etc.:—
Depreciation on chains .....0.03025 W(H + L)
buckets .....0.05242 W(H + L)
trough, gates, etc. ....0.01 WL
sprockets, drive, etc. ..0.55 W
Depreciation account—0.00827 W(H + L) + 0.001 WL + 0.055 W

Total depreciation (summation) = 0.09094 W(H + L) + 0.011 WL + 0.605W

Then:—
Yearly Burden = 0.13380 W(H + L) + 0.0365 WL + 1.0725 W
N = Number of hours (total) Carrier is in use per year.
P_c = Price (cost) of a horsepower per hour.
Cost of power .....$(0.00103\ L + 0.00133\ H)WNP_c$
attendance ....$(0.0000145\ L + 0.000075\ H)WN$
supplies .....$(0.0000455\ L + 0.000045\ H)WN$

Burden depending upon use of Carrier:—
$= (0.00103\ L + 0.00133\ H)WNP_c + (0.00006\ L + 0.00012\ H)WN$

$$N.O.C. = \frac{13380(H + L) + 3650\ L + (103\ LP_c + 133\ HP_c + 6L + 12H)N + 107250}{100{,}000\ N}$$

Formula XXIV.

Carriers with pivoted buckets.

Average cost of chain .....0.2520 W(H + L)
buckets .....0.4504 W(H + L)
rails, etc. .....0.0180 WL
sprockets, drive, etc. ..5.5 W
reciprocating feeder ....0.25 W
Total average cost = 0.7024 W(H + L) + 0.018 WL + 5.75 W

Fixed charges:—
Interest.... 6% total cost
Insurance.. 1%
Taxes .... 2%—¾ cost
= 0.05970 W(H + L) + 0.0153 WL + 0.4888 W

Depreciation, renewals, repairs, etc.:—
Depreciation on chains.....0.0315 W(H + L)
buckets .....0.06756 W(H × L)
rails, etc. .....0.002 WL
sprockets, drive, etc.....0.55 W
reciprocating feeder ....0.032 W
Depreciation account—0.0099 W(H + L) × 0.0002 WL + 0.058 W

Total depreciation (summation) = 0.10896 W(H + L) + 0.0022 WL + 0.64 W

Then:—
Yearly burden = 0.16866 W(H + L) + 0.0175 WL + 1.1288 W
N = Number of hours (total) Carrier is in use per year.
P_c = Price (cost) of a horsepower per hour.
Cost of power ... ..$(0.00028\ L + 0.00108\ H)WNP_c + 0.009\ WNP_c$
attendance .$(0.0000145\ L + 0.000075\ H)WN$
supplies, etc..$(0.0000455\ L + 0.000045\ H)WN$
Burden depending upon use of Carrier:—

$$N.O.C. = \frac{16866(H + L) + 1750L + (28LP_c + 108HP_c + 6L + 12H)N + 112880 + 900NP}{100{,}000\ N}$$

Formula XXIV-a.

Examples:—

1. Conditions:—
Bucket Carrier—Rigid Buckets—Rectangular Path
Horizontal travel of load (total) .....I.D. = L = 100′ 0″
Load elevated (total) ..... = H = 50′ 0″
Service:—2400 hours per year ..... = N
Cost of power:—$0.02 per horsepower hour = P_c

$$N.O.C. = \frac{2372000 + 1539 \times 2400 + 107250}{100{,}000 \times 2400} = \$0.02572$$ per ton of material handled

2. Conditions:—
Same as Example 1 except that service is for but 1200 hours per year.

$$N.O.C. = \frac{2372000 + 1539 \times 1200 + 107250}{100{,}000 \times 1200} = \$0.03605$$ per ton of material handled

3. Conditions:—
Bucket Carrier—Pivoted Buckets—Rectangular Path
Horizontal travel of load (total) .....ID = L = 100′ 0″
Load elevated (total) ..... = H = 50′ 0″
Service:—2400 hours per year ..... = N
Cost of power:—$0.02 per horsepower hour = P_c

$$N.O.C. = \frac{2704900 + 1364 \times 2400 + 112880 + 43200}{100{,}000 \times 2400} = \$0.02556$$ per ton of material handled

4. Conditions:—
Same as Example 3 except that service is for but 1200 hours per year.

$$N.O.C. = \frac{2704900 + 1364 \times 1200 + 112880 + 43200}{100{,}000 \times 1200} = \$0.03748$$ per ton of material handled

The examples cited are based on conditions frequently found in actual practice, and bring out two interesting and important facts: First, that the hours of service of a bucket carrier installation have considerable effect upon the net operating cost of the system, and second, that the hours of service bear a greater effect upon bucket carriers with pivoted buckets than upon those in which the buckets are rigidly attached to the chains and must therefore scrape the load over horizontal stretches. The first of these facts is because the items depending upon the cost of power are relatively small compared with the other factors entering into the question of net operating cost. The items chargeable to depreciation are by far the most important, and these vary little, whether the carrier is in use continually or only half time, for the wear and tear on a well cared for carrier that is in continual use is little, if any, greater than

the general depreciation that is bound to occur in an equipment allowed to remain idle half the time. The second fact is due the cost of necessary power to operate the system being even relatively smaller in the case of the more refined bucket carrier than in the case of carrier with buckets rigidly attached to the chains, making it even more imperative to use the carrier with pivoted buckets continually if the greatest benefits are to be attained. A comparison of the net operating cost of a bucket carrier with the net operating cost of a combined system of bucket elevator and any other conveyer so far discussed shows that the advantages of the more flexible system is rather a matter of convenience than economy. It costs more to operate a bucket carrier over a given path than it would to operate a combination of bucket elevator for the lifting operation and any conveyer, even one as relatively uneconomical as a flight conveyer, for the horizontal carry of the load. This is due, of course, to the much greater power requirements of the empty bucket carrier than is required for the similar work entailed in running both the elevator and conveyer without load. Nevertheless, bucket carriers do possess the advantage of simplicity and, though somewhat more expensive to operate than more complex systems, are excellent for many installations where the cost of operation is of less importance than convenience. Their greatest disadvantage is that a breakdown means a shutdown unless every possible provision is made to provide other means of handling part of the load while necessary repairs are in progress.

IMPORTANT FACTORS IN THE DESIGN OF SEWERAGE SYSTEMS.

IN the construction of a new sewerage system, or of new sewers, one of the problems which first arises is the question, shall the sewers be built on the combined or on the separate system, or partly on both? The question often cannot be answered without careful study, as consideration has to be given to numerous factors. Two factors of the greatest importance are the questions of cost and of sewage disposal. In a paper presented on October 7th to the convention at Wilmington, Del., of the American Society of Municipal Improvements, Mr. John H. Gregory, consulting engineer and sanitary expert, of the firm of Hering & Gregory, New York City, discusses some phases of the subject, as well as some of the relations which the sewers bear to the problem of sewage disposal, as follows:—

As a general proposition, where both sewage and storm water are to be removed in artificially constructed channels, it is probably safe to say that the cost of building a combined system, in which both the sewage and storm water flow in the same channel, generally spoken of as a combined sewer, is less than that of constructing a separate system, in which the sewage flows in one set of pipes, frequently called sanitary sewers, and the storm water in another set, called storm water drains. This is especially true where the territory to be served is more or less closely built up and the streets are already surfaced or paved.

On the other hand, in suburban territory, not closely built up and not likely to be so built up in the near future, and where the storm water is easily and quickly diverted into natural watercourses, the separate system will in general cost less, for the reason that the sanitary sewers need only be built at first, the construction of the storm water drains being deferred for a period of years, or only such drains built as are immediately required. The cost of building a combined system in such a territory might easily be so great as to be actually prohibitive, whereas, the construction of the sanitary sewers of a separate system, as just outlined, could be carried out and would serve all requirements for a considerable period of time.

Topography an Important Consideration.—With steep grades and relatively high velocities in the sewers, it might prove more advisable, on account of the relatively small additional cost, to build combined rather than separate sewers, although the character of the development of the territory might hardly be such as to require the removal of the storm water by this means.

In narrow streets and in congested districts combined sewers have one advantage in that only one sewer is required, thereby reducing to a minimum the amount of sub-surface obstructions. True, the combined sewer will be slightly larger than the corresponding storm water drain which would be required, but the increase in size of the latter is generally so small as to be of little importance. With the separate system, however, two pipes are required, and sometimes three, when a sanitary sewer is laid on each side of the storm water drain, this condition being forced when the storm water drain has to be built so close to the surface of the street as to prevent the carrying of house connections over it.

Again, with the combined system, but one house connection is needed, whereas with the separate system, especially in closely built-up districts with paved yards and areas, two are required, one for the removal of the sewage and the other for the removal of the storm water from roofs, paved areas and other impervious surfaces. The practice of discharging storm water across the sidewalks to the gutters is not one to be recommended. The storm water is, however, sometimes removed by pipes laid just below the surface of the sidewalk and discharging at the gutter. Such pipes frequently give trouble, and often would not be low enough to drain paved areas adjacent to or in the rear of buildings. Two house connections, of course, cost more than one, but not necessarily twice as much as one.

With a combined sewer laid in the middle of the street, as is generally the case, the cost of the house connections to the abutting property owners on each side of the street is equalized. With a separate system the cost of the house connections may be greater to the property owners on one side of the street than on the other, unless the sanitary sewer and storm water drain are equally distant from the centre of the street. If the connections to the curb or property line are put in at the expense of the municipality the cost to the abutting property owners as a whole is as nearly equalized as possible.

Combined sewers are generally laid on flatter grades than separate sewers and may increase the area which can be served without pumping. They may even eliminate pumping entirely. It sometimes happens that combined sewers can be advantageously adopted for a part of the system and separate sewers for the remainder. The writer has in mind one of the large cities in the east where no pumping is required and in which three-quarters of the city is sewered on the separate system and one-quarter on the combined system. The section of the city sewered on the combined system was too low to be sewered on the separate system without pumping and it was in order to avoid pumping that this section of the city was sewered on the combined system.

Higher velocities are required in combined sewers in order to prevent the deposition of grit. Velocities which would be permissible in sanitary sewers would not give satisfactory results in combined sewers. Deposits would be likely to accumulate, especially if a great variation existed between the minimum rate of dry weather flow and the maximum rate of storm flow. When deposits occur in combined sewers organic matter is likely to be held back and settle out or become stranded. If putrefaction of this organic matter takes place before it is washed away malodorous conditions arise. With a long-continued very low dry weather flow deposits may cause the sewage to be ponded with the result that the sewage may become stale, or possibly septic, a condition which should by all means be avoided, independent of whether the sewage is to be treated or not.

The Disposal of the Sewage.—If the sewage is to be discharged into a body of water without any treatment whatsoever, a condition less and less likely to arise in the future, combined sewers would frequently offer the simplest and cheapest solution of the problem. If, however, the sewage is to be treated, separate sewers have certain advantages. In order to limit somewhat the scope of the paper it will be assumed that the sewage must receive some treatment before final discharge and that the treatment will be at one point. Further, that ample opportunity is afforded for the discharge of storm water without having to carry it any great distance.

Sewage treatment works cost money. It is therefore desirable to keep them as small as possible, and in order to do this the volume of liquid to be handled must be kept at a minimum. Rarely, if ever, would it be the case that all of the storm water would have to be treated; hence in this discussion the question of treating other than the first wash of the streets, in addition to the sewage, will not be considered.

With a separate system the volume to be handled at the treatment works is the total sewage flow in the sanitary sewers. The liquid is made up of house sewage, ground water leakage and trade wastes. The flow may, however, be increased in times of storm by taking in the first wash of the streets from the storm water drains, should it be found necessary or desirable to treat the first wash.

With a combined system, under dry weather conditions, the volume to be handled ordinarily is what is commonly spoken of as the dry weather flow, and is also made up of house sewage, ground water leakage and trade wastes. In times of storm, however, the flow in the combined sewers is increased by the storm water from the streets. The liquid then consists of a mixture of house sewage, ground water leakage, trade wastes and storm water.

The effect of the storm water in combined sewers is two-fold—it not only increases the volume of liquid flowing but it changes its character. The first wash from the streets is often exceedingly foul and may increase the organic content of the liquid flowing in the sewers, giving what may be called a stronger sewage. As more and more storm water enters the sewers the storm water becomes cleaner and cleaner, and with the greatly increased flow in the sewers the organic content of the liquid is decreased, resulting in what may be called a weak or dilute sewage.

The volume of liquid to be handled at the treatment works from a combined system depends on whether only the dry weather flow or the dry weather flow plus some storm water is to be intercepted. If only the dry weather flow is to be intercepted, then the volume to be handled at the treatment works would, in general, be substantially the same from the combined system as from the separate system.

One fundamental difference between the two systems, however, exists. With the separate system no raw sewage escapes to the streams or watercourses, while with the combined system raw sewage must at times be discharged into them. If it is planned to intercept only the dry weather flow, then, during storms, just as soon as the flow in the combined sewers exceeds the maximum rate of dry weather flow the surplus flow, over and above that which can be intercepted, escapes, with the result that a mixture of sewage and storm water must reach the streams.

It is true that the overflow of raw sewage from combined sewers into the streams ordinarily would take place only during periods of storm, but even the occasional discharge of raw unscreened sewage into a stream is a question which must be carefully considered. It might be the case, and probably often would be the case, that as far as the temporary reduction of dissolved oxgyen in the stream is concerned no harm would be done, but floating particles of paper and faecal matter are offensive to the sight. If, however, the stream into which the overflow of sewage would take place is sluggish and with but little velocity it may easily be that the continued overflow of sewage into it, from time to time, with the accumulation of sludge deposits on the bottom, would lead to offensive conditions.

Consideration for the Community.—While considering the question of the overflow of raw sewage from combined sewers one point of view of the public should not be overlooked. In general, the public knows but little of the difference between the separate and the combined system. They know that sewers are needed, that the sewage must be treated before being finally disposed of, and that a disposal works must therefore be built. Their natural inference is then that all of the sewage will be treated at all times. If the separate system is adopted—well and good. But if, instead, the sewers are built on the combined system and the public sees raw sewage, even if dilute, discharged into the streams from time to time will they be satisfied? And again, will the state authorities be satisfied? The question is one, aside from dollars and cents, which should and must receive the most careful consideration.

With a combined system, in order to reduce the number of times during the year that raw sewage would overflow, it might be planned to intercept some storm water as well as the dry weather flow. One direct effect which this would have on the sewage treatment works would be to increase their size, and consequently their cost, over and above that which would be required if the separate system had been adopted.

If it is found desirable or necessary to intercept and treat the first wash from the streets the separate system is more advantageous than the combined system, as by its adoption no overflow of raw sewage to the streams will take place. The storm water drains receive only storm water and the first wash from the streets can be intercepted in the storm water drains and discharged either into the sanitary sewers, or into the intercepting sewer leading to the treatment works. As the flow in the storm water drains increases, the surplus water, over and above that intercepted, overflows to the streams but carries no sewage with it.

The separate system, under certain conditions, offers greater flexibility in the disposal of trade wastes than does the combined system, unless the first wash of the streets is to be intercepted and treated. Some trade wastes are offensive and if discharged into the sewers in such a condition must be treated. On the other hand, some trade wastes are inoffensive and can be discharged direct into the streams without causing any nuisance or trouble.

With the separate system the offensive trade wastes can be discharged into the sanitary sewers and the inoffensive wastes into the storm water drains. The offensive trade wastes only would then be carried to the treatment works. With the combined system all of the trade wastes, the inoffensive as well as the offensive ones, would have to be intercepted and carried to the treatment works, with the result that the treatment works would have to be somewhat larger in size, and hence would cost more than would be the case if the separate system had been adopted.

With a community which is largely residential in character, the volume of trade wastes would affect but very little the total sewage flow. With a manufacturing community, however, the trade waste might amount to quite a large percentage of the total flow and in extreme cases might equal in volume the house sewage. Under such conditions it is evident that, if any considerable percentage of the trade wastes is inoffensive, separate sewers would be of decided advantage, as they would permit of the inoffensive wastes being discharged direct into the storm water drains, the offensive wastes only being discharged into the sanitary sewers and by them carried to the treatment works.

With a combined system automatic regulators are generally used on the connections between the combined sewers and the intercepting sewer to limit the amount of flow from the combined sewers to the intercepting sewer. With a separate system automatic regulators are not required unless the first wash from the streets is intercepted in the storm water drains. Automatic devices in sewers, as a general proposition, no matter how well designed, are to be avoided wherever possible.

The Removal of Grit.—The presence of grit at a sewage disposal works is generally more or less of an annoyance, especially when the sewage has to be pumped and passed through settling tanks. With combined sewers, receiving as they do storm water from the streets, a considerable amount of grit must be expected to reach the disposal works, not only during wet weather but during dry weather also. With separate sewers the amount of grit received at the disposal works is relatively small unless the first wash from the streets is intercepted in the storm water drains and carried to the disposal works.

It has been suggested that a considerable amount of grit could be prevented from reaching the disposal works from combined sewers by inserting a catch basin or sand catcher on each connection between the combined sewers and the intercepting sewer. It is probably true that such would be the case, but it is a question whether this would be a good method of removing grit. In the first place these sand catchers would sooner or later fill up, and unless cleaned at proper intervals would fail to serve the purpose for which they were built. Again, it is very probable that more or less organic matter would be deposited in them, especially when only the dry weather flow, consisting as it would mainly of sewage, was passing through them. The retention of organic matter would lead to offensive conditions as soon as putrefaction began.

The inserting of sand catchers between storm water drains and an intercepting sewer would seem to be a more practicable proposition as the possibility of retaining offensive matter from sewage would then be eliminated. The sand catchers would still, however, have to be cleaned in order to make them effective.

With combined sewers or with separate sewers in which the first wash from the streets is intercepted in the storm water drains grit must be expected. Such being the case, it is a question if the simplest way of handling the grit is not to admit it into the intercepting sewer from the combined sewers or storm water drains, without attempting to intercept any portion of it, and then to transport it with a good velocity in the intercepting sewer direct to the sewage disposal works. Even with sand catchers on the connections between the combined sewers or storm water drains and the intercepting sewer enough grit is sure to reach the sewage disposal works to require its removal before the sewage is pumped or passed through settling tanks. The removal of grit at one point instead of at numerous points has many advantages.

The common practice of removing grit at a sewage disposal works is to pass the sewage at a slow velocity, roughly about one foot per second, through a grit chamber, the grit settling out and being retained on the bottom of the chamber. In large works mechanical means are provided for removing the grit from the grit chamber, but in smaller works it is common practice to drain out the liquid from the grit chamber and to then shovel the grit out by hand.

With a separate system, in which the first wash from the streets is not intercepted from the storm water drains, a question arises as to the necessity of providing a grit chamber at the sewage disposal works. Practice varies. At some disposal works grit chambers have been provided and at others not. If the sanitary sewers are properly designed and built and are provided with tight covers but very little grit should get into the systems, but with macadam or dirt streets and perforated covers some grit must be expected. The safest plan, under ordinary conditions, seems to be to provide a grit chamber, even if it be a small one. The grit would require removal only at more or less infrequent intervals.

Perhaps the question may arise as to the necessity of removing the grit. It would, of course, be perfectly possible to pump the grit along with the sewage, but this would cause unnecessary wear and tear on the pumps. Again, if the grit is not removed before reaching the suction well, it may easily settle in and clog up the suction well causing thereby a shut-down until the well is cleaned out.

If the grit is admitted to the settling tanks it may cause trouble there. It depends, of course, on what type of tank is used and on the method of operation. If the tank is an Imhoff tank the grit, by settling down into the sludge digestion chamber, may check or prevent the proper digestion of the sludge and consequently affect the satisfactory operation of the tank. The admission of grit to a septic tank may also interfere with its satisfactory operation. If admitted to a plain settling tank, which is cleaned out at frequent intervals, the main trouble to be expected would be in the cleaning out of the tank.

With sewage from a combined system the volume of sludge accumulating in settling tanks is greater than with sewage from the separate system. It may even be nearly

(Continued on page 680.)

THE PROTECTION AND UPKEEP OF ROAD EQUIPMENT.*

By Daniel J. Hauer,
Construction Economist and Consulting Engineer.

NO matter whether roads are built by contractors or by day labor forces under the direction of engineers, the item of plant and equipment is one of the prominent factors of cost. Inadequate plant means to materially increase the cost of construction. Only recently the writer stood watching some road building upon which only a few tools were being used, and most of them were ill-adapted to the work. It was difficult to accurately calculate the exact amount of money that was wasted, due to a lack of road equipment, but it was easily estimated that the cost of construction was increased at least twenty-five per cent. Likewise, too much plant can make an added cost. Even with the proper plant, and handled in an efficient manner, the plant item in road construction is a larger per cent. of the total cost of the work than in most other classes of construction. This is due to two causes. First, the plant necessary to build a wagon road is much more expensive than that to build, to illustrate we will say, a railroad. With light grading on both, the same equipment will be needed to do the excavation. For the railroad a small concrete mixer may be needed, and some track-laying tools to complete the job. On the other hand, for the wagon road there will be much hauling of road materials, thus wagons and a traction engine will be needed, then road scrapers or graders, and spreading machines, water sprinklers, oil sprinklers, and heating apparatus will be necessary; scarifiers, harrows and rollers must be used, while for concrete culverts and bridges, mixers, derricks, buckets, barrows, and other appliances are called for to do the job in an efficient manner. The writer has constructed a section of a railroad costing about $100,000, with a plant costing only about $5,000, while a contract for less than $50,000 of wagon road work took an outfit costing nearly $20,000; forty per cent. of the total cost instead of five.

The second reason for the larger cost of plant for wagon road construction is that this class of work is let out in small scattered contracts that are uneconomical from a constructive standpoint. The season, too, for road building in nearly every section of the country is short.

Naturally the life of any machine is dependent upon the use and care given it. The longer the life, the less the annual depreciation, consequently some of the high plant cost can be eliminated from road construction by the proper care and upkeep of the equipment, and by selecting the most improved and economical types.

As far as possible the same machines should be used for many different purposes. This can be done in two ways: By trying out machines designed for one particular kind of work for other kinds, and by adding attachments to machines that thus adapt them to three or four different things.

To illustrate, a contractor once found by experimenting that a certain kind of road grader would spread crushed stone for macadam at a very much less cost than it could be done by any other known method, at that time. Then a road roller that can be used as a traction engine, with a scarifier attachment, and likewise for operating a stone crusher, or other machines, can be said to be four tools in one; not that it is possible to use it for more than one purpose at a time but in the present method of building roads a roller is only used a small portion of the time, so it is economical to adapt it to as many uses as possible. In this manner the cost of plant, or rather the investment in plant, can be maintained at the minimum.

In like manner, wagons, which are an important factor in road building, should be of the most improved type, and adapted as far as possible to all kinds of hauling. So, too, with concrete mixers. Some contracts demand a hot mixer as well as one for mixing ordinary concrete. Money is saved when one mixer will answer for both purposes.

Another item in the cost of plant is in the character of the plant purchased. Cheap and poorly made plant means money lost to the contractor in several ways. Delays occur through breakdowns and these are always expensive. Cheaply made tools mean continual repairs and a short life, and are an added expense to any job. Only well made tools should be used. A guarantee as to the construction of a machine can and does mean little. It does not mean payment for delays caused by breakdowns nor for poor work being done. The ability of a manufacturer for swearing his product is a good one is not a help to a contractor or engineer in getting his work done, nor in showing that the machine in question is well built. The greatest asset is in buying from a firm of recognized responsibility, one of integrity, and one that is so well advertised that they must stand behind their products by putting into them only the best of materials and workmanship. This is the best guarantee possible. This means work done at a low cost. A firm with such a reputation means that thousands of dollars have been spent by them and their customers in obtaining these results. The new customer profits from these past expenditures.

These are all possible factors in plant and equipment, upkeep and maintenance cost. The problem that the contractor and construction engineer must solve in this connection is a very difficult one, owing to the many adverse conditions.

Road work is done in comparatively short stretches, usually in a single season, which varies in length from about one hundred to one hundred and eighty days, according to the climatic conditions. A contractor's plant is moved on to a job, and is used along the line of the work, part or all of the time during the season. Much of a contractor's plant is made up of transportation machinery, and even other items of plant are only working in one place for a few days at a time, so that to protect plant while at work on such jobs is very difficult, and in many cases any kind of a protection is a detriment, and a great hindrance to the free movement of the men and teams.

All machinery should be protected when it is not being used, and some when in use. Boilers at work, use much more fuel when not protected. Some kind of a house, built in sections should always be used to protect boilers. Such sheds can have one side left out, and a canvas curtain used when necessary. If the sides and tops are built in sections they can be hooked together with hooks and rods and staples so as to be rigid enough to stand up against the wind and weather.

*Read at American Road Congress, held at Detroit, Mich., Sept. 29 to Oct. 4, 1913.

Machinery that cannot be protected while at work, can be covered with canvas coverings over night, during rainy spells and at such times when they are not in use. Every traction engine and roller should be thus protected. Steam drills and such tools can be covered with a canvas jacket. The machinery part of a concrete mixer can be so protected, and also pumps and other equipment. Heavy water-proofed canvas will be found to be excellent for this purpose, and not only keep the machinery clean from dust and mud, but will likewise prolong the life of the equipment. As the canvas becomes worn from use, it must be re-treated with water-proofing liquids to preserve it.

At the end of the season, with the job finished, the question always arises, "What shall be done with the plant?" To move it from its present place to some central storage point, will mean an added expense to get it on to a new job. If the work on the same road is to be continued the next season the entire outfit may have to be moved back. The plant can be moved to the next job at the minimum cost from the site upon which it last worked. Then the question comes as to how repairs should be made, and the protection to be given the plant from the winter weather.

Situated away from the machine shops, the proper overhauling cannot be given to all the plant, but it will be possible to replace many of the worn and broken parts with new ones, tighten up all loose keys and nuts, true up all bearings, and do all repairing that can be done in the open. Then all iron and wood work can be painted. This is a protection not only against the weather, prolonging the life of the plant, but is also a business proposition that pays well, as every one is impressed with machinery that looks well, and paint covers a multitude of defects.

In some localities it is possible to obtain an empty warehouse or barn in which the various machines can be stored while they are idle, or during the winter season. This keeps them entirely out of the weather, and also allows of repairs being made under cover, which means not only quicker, but also cheaper work.

For winter storage it is also possible to group a number of machines together, and build over and around them a temporary shelter made of cheap boards and single ply tar paper, which will last during a winter season. By using the tar paper, the boards can be spread six inches or more apart, both on the sides and roof. Around this temporary shed a ditch should be dug so as to prevent surface water from getting to the machines.

If it is not possible to protect the machines by any of these methods, then the canvas coverings can be resorted to, with fairly good results. These covers should, as far as possible, be shaped to the machine upon which they are to be used. Good and substantial brass eyelets should be fastened in the well bound edges, so that the coverings can be tied tightly to or under the machines, otherwise the wind will flap them loose, soon beating the covering into shreds, as a flag is worn out by the wind, and thus exposing the machine to the weather. Canvas coverings made to fit any machine will always be found useful in protecting machines over night or when not in use for a few days.

Whenever machines are not stored for the winter in buildings, they should be stripped of their brass and glass parts, otherwise these fixtures will be broken or stolen, which means a serious loss. The parts from each machine should be placed in a separate box, nailed up and properly labeled, the box being stored away for safe keeping. If the machines are stored in a building, it is not necessary to take off parts, as if any one breaks into the building they must go to the trouble of taking off the brass, while if the parts are stored in boxes, the rascals take box and all, giving them much less trouble, and thus assisting them in making a clean sweep of all the brass fixtures.

When a new machine is purchased, there should always be bought at the same time a number of spare parts, which should be kept on hand to be used as needed. No man can build a machine that will not break down in some vital part sooner or later. A breakdown in a construction job means not only a delay, but a waste of money, for even if men can be laid off and not paid, or can be given other work, yet the job, due to the changes made necessary by the breakdown, will not be worked in the most economical manner. It is true that many contractors do keep some spare parts, but they seldom have on hand enough, or the proper ones, due to the fact that as the parts are used to replace broken ones, new ones are not ordered from the factory. Then either one of two things occurs: the job is shut down or some part of it, or the machine is worked with the broken part until a new one can be ordered and put in place. This means that the machine is racked by the work it does, doing permanent injury to it.

A good blacksmith shop on the job, equipped with forge for heating heavy steel and with stocks and dies for bolts and pipe, and with good drills and vises, will be found to be a great assistance in the upkeep of road equipment. For heavy machines a few roller bearing or small hydraulic jacks will be found useful in making repairs and renewals.

Small tools can be repaired promptly in a blacksmith shop. Attention should be given to these as well as to the larger machines. To prevent such tools being lost, they should not only be branded with a die of the contractor's name or initials, but they should likewise be painted with a set of colors, selected by the contractor, to designate his equipment and advertise his business. These colors can be used on the head of some tools, and in most cases on the handles. Tools can thus be seen at some distance, and thus prevent their being stolen or lost. All bright parts of tools and machines that can't be painted should be well greased so as to prevent rusting.

Many of these suggestions seem useless, or more or less self evident, but any one who has much to do with road construction knows that tools and machines are scattered along the entire line of a piece of new road construction, just where they were last used, and there they stay, neglected, until they are needed again. Then they are found out of order, and to repair them, frequently new parts must be ordered, some days intervening before such parts arrive. The tool or machine depreciates greatly in value by such treatment, and thus contractors are compelled to figure a heavy plant expense item against every job. The cost of caring for this equipment is much less than the depreciation figured against it from neglect.

Such extra costs mean higher prices for road work, and as there are many thousand miles of roads that need improving, every dollar wasted means less mileage built each year. Both engineers and contractors are interested in obtaining good roads, and they should do everything possible to save money in the construction of roads.

STANDARDIZATION OF STREET RAILWAY SPECIAL WORK.

IN line with the policy of standardizing as much of the material used by it as possible, the Metropolitan Street Railway Company, of Kansas City, Mo., has adopted a set of standards for special work which are very complete. The standards have been tried out for a year or more, and the results so far obtained are very satisfactory. They were worked out under the direction of Mr. A. E. Harvey, chief engineer, who describes them in an article in "Electric Traction," and includes details of rail curvature sections, lengths, etc., in connection with them. The following information is extracted from it, to show how standardization methods are applied in cases where layouts are renewed or new work put in, it being exceedingly desirable that the work be of such character as to be interchangeable and renewable, piece by piece, from stock.

In the establishing of something that could be standard the following points were included in Mr. Harvey's problem as it had to be solved: rail section, radii of curves, length of pieces, material, design, and various minor details in regard to the assembling of the work which present themselves as the larger details are developed.

Rail Section.—In the selection of the section of rail to be used in the special work, consideration had to be given to the fact that a very considerable percentage of the tracks in the paved streets of Kansas City were laid with 100-lb. A. S. C. E. section. This rail has proved exceedingly satisfactory; there was no reason why the section should be changed, and it was desirable that the special work should be constructed so that it would fish with this section without the use of compromise joints. Various problems presented themselves in the detailing of this special work, particularly the question of guarding, but with this problem solved, it was decided that this was the most desirable section for use in the construction of the work.

Fig. 1.—Special Work Standards for Double Track Closed "Y" and Crossing.

Radii of Curves.—The radii of the curves selected for the standard work is controlled to a certain extent by the width of streets in Kansas City. Some of these are of such width that it was impracticable to use a curve of less radius than 42.5 ft. This, therefore, was adopted as the minimum. There are few places where a larger radius than 65 ft. can be used. These two radii, with one intermediate standard of 50 ft., were adopted as standard, and the special work designed upon this basis. These curves were all used in connection with Lorain spirals No. 2. Using these radii as a basis, the various combinations that might be used in any layout on an angle

of 90 degrees are detailed in the manner shown in the accompanying figures. These combinations were all laid out on an angle of 90 degrees, which could in almost

Material.—Recognizing the fact that in some locations one kind of material might be required and in others a cheaper grade, the question of standard material

every case be used in Kansas City, particularly where a few minutes can be thrown in the angle of the next block.

Length of Pieces.—It will be noted that the pieces are detailed so far as length is concerned, making a minimum number of joints, and establishing the length of each arm so that standard pieces are interchangeable. Under this design a minimum number of standard pieces is secured, as there are quite a number of pieces that are common to both a single track turnout and all the more complicated combinations; that is, the switch frogs and diamonds are the same in the plain turnout crossing the second track as would be found in a double track closed wye. The number of different kinds of switches is reduced to two, a right and a left, except that in some of the more complicated layouts there is a slight variation in the arm lengths for switches and mates, and in layouts which are designed for clearance, and which are used where it is practicable to obtain such clearance, a 150-ft. radius is used instead of 100 ft. The advantages of these standards and the interchangeability of these switches are manifest. In future years the cost of renewals would be very much reduced, and repairs and renewals could be made from stock without carrying a stock of any great amount. The advantage derived from it at present is that the work, as required, may proceed by taking stock pieces and assembling them in any combination required, and where material which might be ordered for one location, upon which the work for any reason might be delayed, may be used elsewhere and not stored indefinitely. All of this would tend to decrease the size stock that it is necessary to carry in our store yard.

has been left open, and the detail of the design only carried to a point where it would not forbid the use of pieces made from either solid manganese, cast bound work, built-up work or cast steel.

Design.—In the detail of the design of this work the most serious obstacle met was that of guarding the T-rail section. Various devices were tried out with more or less success, but it was finally settled that the guard

best adapted to this section was the 50-lb. T-rail. A section of this in its relation to the main rail is shown in Fig. 4, which also illustrates the standard chair adopted for the securing of this rail, or rather chair in combination with tie plate. This, with the omission of the plate and a slightly different arrangement for attaching it to the tie is adaptable to the use of steel ties.

This chair consists of a malleable casting in combination with the plate, together with a brace and wedge. The strain of the guard rail from the main line is taken eventually through the plate under the base of the rail and against the screw spike on the outside of the rail. A number of advantages are secured in this device:

1. Both the main rail and guard rail are standard sections that are rolled by almost any mill, and can always be secured at standard prices and for less money than specially rolled sections.

2. The guard rail is secured to the main rail without the use of bolts and without the necessity of drilling through the main rail, a distinct advantage in construction as well as in renewals.

3. The strain that comes upon the guard rail is transmitted directly from the head through the casting instead of being transmitted through the web of the rail, and at a point where considerable leverage would be secured against the bolt as it is ordinarily applied.

4. The guard is renewable without any interference whatsoever with the running rail. The paving does not have to be removed from the outside of the main rail at all, and on the inside only to the base of the 50-lb. rail, which can be loosened up and a new rail slipped in place, or the old rail adjusted for wear, and moved in closer to the main rail, either by a light grinding of the bearing points on which the guard rests, or by removal of shims, which

Fig. 6.—Standard Built-up Frog With Manganese Filler.

The connection of this guard to the pieces is one detail of the design that had to be solved. It was undesirable to put a joint in this guard rail connecting up to a piece of the guard cast in the cast-bound work, or guard would connect up closely with the manganese plate in cases of cast-bound work; and in cases of solid manganese work a small pocket at the end connecting with the manganese guard, and in cases of built-up work to attach it securely to the built section by means of the standard chair. In designing these standard pieces it was the object so far as possible to specify only those points which were necessary to obtain the results at which we aimed, and not specify those things that would interfere with the manufacturer's design or shop practice.

The most important feature in the design of street railway frogs is the detail of the flangeway, particularly where the flange bearing is desired. The writer believes that this matter has not been properly understood, nor the best results obtained in the past in flange-bearing work, and the work which we are now specifying is designed to overcome the objectionable features that exist in flange-bearing work as it is generally put upon the market.

A flange bearing as it has been understood in the past, and as it has been designed, has aimed at having just at the intersection a floor upon which the flange would rest while passing over the intersection. In theory this is perfect. In practice it has led to a great deal of trouble.

It is impossible to get a flangeway that is just the depth of the flange. It is either itself worn too deep, it may be constructed too shallow, treads wear and wheel

otherwise attach it to a piece of other design. Any joint of that kind is necessarily unsatisfactory, and moreover, the part of the guard that was not removable from one of the pieces would wear, and could not be renewed or flanges become long so that the percentage of wheels that will take the flange bearing and pass the intersection without a blow is exceedingly small, and where the flangeway is made shallow enough so as to take care of this

adjusted as could the balance of the guard around the curve. The problem was solved by making a pocket in each of the pieces and the T-rail guard was inserted and spelt ered in this pocket, running in so that the detachable the wheels, particularly worn wheels, will strike the metal in the bottom of the flangeway a blow that endangers the flange, chipping it. The effect is very much the same as the placing of a block of steel in the flange-

way for the wheel to run over. It results in a jolt and a blow that is detrimental to the wheel, to the car and to the special work, making a noisy and hard riding crossing.

The theory upon which we have proceeded with this work is that the wheel should be picked up on this flange with as light an angle of impact as possible at a considerable distance from the intersection, and ride upon its flange entirely across the intersection and be let down again upon its tread. Every time this proposition is presented some one will say: "What does this do to your wheel flanges?" What is the other doing to the special work and the paving? The taking of a wheel with a light angle of impact and riding it upon its flanges is easier on the track, paving, the wheel and the car, on the nerves of the public, and on adjoining buildings. It is not only upon this theory that the design of the flangeway and special work is based, but from actual experience with these flangeways, it has been found that all that has been said in regard to this matter is confirmed by results obtained in practice.

Other details of the special work pieces are rather immaterial so long as the design and profile of the flangeway are carried out, and this flangeway may be built in any type of work. In cast-bound work it can be obtained if the plate is made large enough, and some work has been furnished in this way, but the manufacturers have overlooked in some cases the object at which we were aiming, and apparently construed the specifications that more manganese was desired, which was not necessarily the case. It is not the amount of the manganese that governs the situation, but the profile of the flangeway. This flangeway is readily made in built-up work where the manganese cross is used as a base upon which may be bolted wings of rolled rail. It is giving good results in our built-up bolted work where the manganese strip, or the manganese filler, is used between the rails. Of course, this profile is readily made in solid manganese, and in that case has the advantage of keeping the treads away from the weaker points at the intersection and prevents chipping.

The writer believes that this question of the profile of flangeways has had a great deal to do in the past with certain difficulties that have been charged to solid manganese work, i.e., where the defect that has appeared in solid manganese, particularly in square crossings, has been due to the blows of the treads of the wheels upon the points, and that this trouble would never appear should flangeways be constructed as described above.

Among other designs, attention is called to our 100-lb. crossing with a flange bearing from end to end for both tracks shown in Fig. 5. This design, it will be noticed, has in it comparatively little manganese and consists of 100-lb. rail bolted to the manganese filler. We have had several of these crossings in service for over a year, and the results that are being obtained from them are exceedingly satisfactory. They are easier on the cars, easier riding and easy to maintain. We have

adopted them as our standard crossing in all work. It may be a little difficult to build in complicated layouts where curves intersect the crossings. In such cases these complicated parts are built in solid manganese.

In the design of switches nothing is specified outside of the outside dimensions of these switches and the section of the rail.

Solid manganese work built with the flange bearings as specified by us is a most satisfactory design, and where constructed in accordance with standards so that pattern charges are not repeated from time to time, its cost will be so reduced and its advantages over other types of work such that it is an ideal special work. It has a distinct advantage over the cast-bound work in

Fig. 11.

In regard to the class of work specified: Cast steel is permissible under our specifications, and nothing is standardized outside of this, except in regard to the dimensions and matters heretofore mentioned that are common to all classes of work. Cast-bound work is acceptable in its usual form, the specifications in regard to that consisting only of those matters relating to the flangeway, to the section of rail, and to the question of keeping the cast iron down on the outside of running rails so that it may not receive a blow from a worn wheel. The writer finds that this is the most common cause of the many defects that appear in cast-bound

that all special work is of the same depth and facilitates the spacing and placing of the ties in special work. This is particularly applicable to the placing of such work on steel ties.

The specifications for standard switches Nos. 1 and 2 are as follows:—

Cast Steel or Cast Bound Switches.—They must conform accurately to the general dimensions shown on Fig. 7.

Switch tongues must be of solid manganese and of heavy design and must be provided with lug for the attachment of spring lock or electric throw. The tongue must be ground to fit closely to its bed. The heel must fit perfectly so as to

work, resulting in the breaking of the casting and the loosening of plates and the rail in the pieces. Built-up work with a manganese filler forming the flange bearing is a type that we are using in some cases. Fig. 6 shows the detail of this design. The principal points of the specifications require that all bolts in this work must be turned, all holes reamed and the bolts put in with a driving fit. This type of work was designed primarily that we should have a type of work that could be built in our own shops without delay, and without the necessity of foundry work. This type has proved exceedingly satisfactory in all respects.

prevent the entrance of snow, ice or sand under the bearing. All parts of the body which might be struck by the overhanging part of the tread on worn wheels shall be kept ¼-in. below the top of the adjoining rail.

For T-rail work the guard rail pocket shall be so constructed that the removable guard extends to the manganese centre.

Solid Manganese Switches.—They must conform accurately to the general dimensions shown on Fig. 7.

Switch tongues must be of solid manganese and of heavy design, and must be provided with lug for the attachment of spring lock or electric throw. The tongue must be ground to fit closely to its bed. The heel must fit perfectly so as to prevent the entrance of snow, ice or sand under the bearing.

Those for standard mates, Nos. 5 and 6, are as follows:—

Cast Steel or Cast Bound Mates.—They must conform accurately to the general dimensions shown on Fig. 8.

Manganese plates shall be of liberal size and of heavy design.

Flangeways shall be 11/16-in. deep for a distance of not less than 6 ins. ahead of and 6 ins. back of the ½-in. point, and shall slope evenly to a depth of 1 in. at the edges of the plate. The inclined portion of the flangeways shall in no case be less than 18 ins. long.

All parts of the body casting which might be struck by the overhanging part of the tread on worn wheels, shall be kept ¼-in. below the top of the adjoining rail.

Solid Manganese Mates.—They must conform accurately to the general dimensions shown on Fig. 8.

Flangeways shall be 11/16-in. deep for a distance of not less than 6 ins. ahead of and 6 ins. back of the ½-in. point, and shall slope evenly to a depth of 1 in. The inclined portion of the flangeways shall in no case be less than 18 ins. long.

Specifications for Standard Frogs Nos. A21, A22, A31 and A32.—Flangeways through manganese plates shall be not less than 30 ins. long, measured along the gauge lines, and they shall extend an equal distance each way from the intersection of the gauge lines. Flangeways shall be 11/16-in. deep for a distance of 4 ins. each side of the intersection of the gauge lines, and shall slope evenly to a depth of 1 in. at the edges of the plate.

All parts of the cast iron body which might be struck by the overhanging part of the tread on worn wheels, shall be ¼-in. below top of adjoining rail.

Flangeways shall be 11/16-in. deep for a distance of 9 ins. each side of the intersection of the gauge lines and shall slope evenly to a depth of 1⅛ ins. at points 2 ft. 9 ins. from the intersection of the gauge lines.

Specifications for Standard Frogs Nos. A29 and A30.—Flangeways through manganese plates shall be not less than 24 ins. long measured along the gauge lines, and they shall extend an equal distance each way from the intersection of the gauge lines.

Flangeways shall be 11/16-ins. deep for a distance of 4 ins. each side of the intersection of the gauge lines and shall slope evenly to a depth of 1 in. at the edges of the plate.

All parts of the cast iron body which might be struck by the overhanging part of the tread on worn wheels, shall be ¼-in. below top of adjoining rail.

Flangeways shall be 11/16-in. deep for a distance of 9 ins. each side of the intersection of the gauge lines and shall slope evenly to a depth of 1⅛ ins. at points 2 ft. 9 ins. from the intersection of the gauge lines.

Specifications for Standard Double Frogs Nos. A41, A42, A43, and A44.—Flangeways through manganese plates shall be not less than 30 ins. long, measured along the gauge lines, for frogs of an angle less than 28 degrees, or less than 24 ins. long for frogs of an angle greater than 28 degrees; and they shall extend an equal distance each way from the intersection of the gauge lines.

Flangeways shall be 11/16-ins. deep for a distance of 4 ins. each side of the intersection of the gauge lines and shall slope evenly to a depth of 1 in. at the edges of the plate.

All parts of the cast iron body which might be struck by the overhanging part of the tread on worn wheels, shall be ¼-in. below top of adjoining rail.

Flangeways shall be 11/16-in. deep for a distance of 9 ins. each side of the intersection of the gauge lines and shall slope evenly to a depth of 1⅛ ins. at points 2 ft. 9 ins. from the intersection of the gauge lines.

Specifications for Standard Crossing No. 51.—Flangeways through manganese plates shall be not less than 15 ins. long, measuring along the gauge lines, and they shall extend an equal distance each way from the intersection of the gauge lines.

Flangeways shall be 11/16-ins. deep for a distance of 2 ins. each side of the intersection of the gauge lines and shall slope evenly to a depth of 1 in. at the edges of the plate.

All parts of the cast iron body which might be struck by the overhanging part of the tread on worn wheels, shall be ¼-in. below top of adjoining rail.

Flangeways shall conform accurately to the profiles shown above.

In case of single track crossing, or single track crossing with double track, the outer arms shall conform to the profile shown for outer arms.

In all cases the specification requires the number of the piece to be plainly cast upon the top surface at some convenient point. When the work is of cast steel or solid manganese, the arms are required to be accurately ground to conform to the rail sections specified for the work.

IMPORTANT FACTORS IN THE DESIGN OF SEWERAGE SYSTEMS.

(Continued from page 671.)

twice as much, as has been found to be the case by comparison of the quantities of digested sludge removed from different Imhoff tanks, some of which have been connected with combined systems and others with separate systems. The greater volume of sludge from the combined system may mean that less organic matter has reached the streams than would have been the case if the sewers had been built on the separate system. If, however, the first wash from the storm water drains of a separate system is intercepted and carried to the treatment works, then the volume of sludge should be approximately the same as if the sewage came from a combined system. Similarly the amount of organic matter reaching the streams should be approximately the same, although it is possible that it might then be somewhat less.

In many instances, probably in the majority of cases, pumping is required in order to pass sewage through a treatment works. This is generally due to the fact that the site of the treatment works is more or less distant from the territory sewered and by the time the sewage has reached the treatment works enough head has been lost to prevent passing the sewage through the works by gravity. It may even be that the sewage would be delivered at an elevation below that of the stream into which the effluent was to be discharged.

With a combined system the total height to which the sewage would have to be pumped would probably be somewhat less than with a separate system, but the difference would not be great. Some saving in fuel might therefore result from the adoption of the combined system, but the same operating force would be required in either case. So long as pumping is required the actual saving in cost due to pumping the sewage against a less head, due to the adoption of the combined system, would be slight compared with the total cost of pumping, including fixed charges.

In conclusion, no hard or fast rules can be given for the adoption of either the combined or the separate system. Each has certain advantages. These, as well as local conditions and cost of construction and operation, must be taken into account. Other things being equal, especially as more and more attention is being given to the question of sewage disposal, the separate system seems to offer greater advantages. With either system, however, to secure satisfactory results, too much stress cannot be laid on the necessity of not only proper design but satisfactory maintenance and operation.

In France, efforts are being made to further a scheme for the development of river communication between Geneva and Lyons. A Franco-Swiss committee has been formed, and a meeting held recently at Satigny was attended by delegates from the Swiss communes in the vicinity of the Rhone. They discussed and supported the advisability of forming local committees to aid in popularizing the scheme.

PRESERVATION OF HEALTH IN CONSTRUCTION CAMPS.

With the word "camp," military or constructional, there has always been associated the thought of liability to pestilence and disease, and it has been more or less of a foregone conclusion that every large camp must pay toll. Without question, however, the value of human life has risen and its safety is viewed more sanely. The scientific prevention of unsanitariness and disease has become a prominent factor in military manoeuvres, and it is to be noted with satisfaction that it has its place of similar importance in the maintenance of construction camps, as well.

The construction of the Panama Canal is memorable in this respect, and the scientific campaign against tropical diseases has been so successful as to rate it as one of the important features of the great piece of engineering. Measures for the maintenance of health were far more comprehensive than had hitherto been attempted. Streets were widened, drained, and paved; houses, as well of the poor as of the rich, were re-built and protected from mosquitoes by screens of wire gauze. The whole ground of Colon, for example, was raised above the surrounding marsh with mud taken therefrom by means of suction pumps. The breeding places of mosquitoes within 100 yards of all permanent habitations were removed, and marshes drained or filled in. The floors of the houses were cemented to afford no refuge for plague rats. Good drinking water has been constantly provided. A fine hospital is maintained.

As a result, the death rate has fallen to 7.5 per thousand per annum, and the total cost has been only about one cent per day per head of population.

Although Canada's undertakings are not accompanied by tropical conditions, the admirable mastery of adversity in the above instance suggests giving more attention to livelihood in our own construction camps. There are many in existence and many more will shortly spring up. In British Columbia there will be the Sooke Lake water supply project, the Burrard Inlet harbour and dock extensions, the tunneling of Roger's Pass, etc. In Manitoba, the construction of the Shoal Lake viaduct will begin early in the spring. In Quebec, there will be the Ottawa water supply project from the Gatineau Lakes, and there are the well-known engineering activities around Montreal and the St. Lawrence. In Ontario, many camps will be active with the opening up of the spring season, chief among them being those on the construction of the Welland Canal. No mention being made of the numerous smaller camps, such as at the many extremities of railway developments, the thousands of men who will be engaged next season in the explicit carrying out of engineers' specifications should be assured immunity from unsanitary and disease-producing conditions in their habitations.

THE VIEWS OF THE PEOPLE ON ROAD IMPROVEMENT.

As announced last week, the Ontario Highway Commission is holding a series of meetings throughout Older Ontario in the interests of the Good Roads movement. The first session was held in Ottawa on October 28th, where representatives of all the municipalities of the Ottawa Valley were present and manifested the intense interest which is being taken in the movement. The sug-

gestions made to the Commission were practical in character, and evidenced a general desire to assist in the bettering of the roads of Eastern Ontario, generally conceded to be seriously in need of improvement.

One point that was particularly emphasized was the belief that it is essential for a permanent and comprehensive good roads policy to substitute for the present statute labor system of maintenance and improvement, a system of municipal or government control and expenditure. It was emphasized that a greater continuity of policy, better men and better supervision of highway construction and maintenance would be secured thereby. It was the general feeling of the session that there is an absolute necessity for a permanent Government Commission to supervise all road construction, and to investigate and apply new and successful methods.

The Commission outlined its aim as being in the interests of rural and urban people alike, and not of any special class of road users. Market roads for the farmers, rather than trunk roads for the automobilists, were the first consideration.

EDITORIAL COMMENT.

The placing under contract of Section II. of the new Welland Ship Canal last week, and the call for tenders for Section V., indicates that there is little delay in getting the project under way. In fact, remarkable speed is being exhibited in disposing of the various sections. Late in July the contract for Section I. was awarded to the Dominion Dredging Company, Ottawa, as announced at an amount approximating $3,500,000. Section III. followed early in September at $9,500,000, to O'Brien and Doheny, Quinlan and Robertson, both Montreal firms. Then, the award of Section II. to the English firm of Baldry, Yerburgh and Hutchinson, at an amount in the neighborhood of $5,500,000 was announced in our issue of last week.

It is understood that, following Section V., Section IV and the remaining four sections will be placed under contract as rapidly as possible.

* * * *

The provincial conference which met in Ottawa last week to discuss the question of pollution of navigable waterways adopted the resolution forwarded by the Canadian Public Health Association, from its Regina convention, asking the Government to consider the desirability of establishing a federal department of public health. Particulars leading up to the framing of this memorial were given in *The Canadian Engineer* for October 16th. The resolution read as follows:—

"Whereas in the past sanitary questions affecting public health have suffered from the non-existence of a federal health department, this conference considers the creation of a federal department of public health might well receive the early attention of the government.

"The conference believes such a department would be of assistance in solving interprovincial problems as to the protection of public health."

A recent number of "The Electrician" states that there are more than 6,000 towns and villages in France at present without a system of distributed public lighting. Of the 4,094 small towns already artificially lighted, 2,673 have adopted electricity, 1,240 gas lighting, and 172 acetylene.

LETTERS TO THE EDITOR.

Discussion of "Bending Moments in Flat Slabs."*

Sir,—The present writer has had occasion recently in his treatise on Flat Slabs† to consider and make application of the general principles of the strength and flexure of flat plates uniformly loaded throughout to the computation of reinforced concrete floor slabs of many panels, especially with reference to the case of those constructed on the mushroom system by Mr. C. A. P. Turner.

While the writer has no fault to find with the method of mathematical analysis adopted by Mr. Elmont, which in fact agrees with his own so far as it goes, he nevertheless feels compelled to say that Mr. Elmont's method of applying that analysis to flat slab design is not, in his estimation, correct, and the conclusions he draws as to the stresses in the steel are not warranted by the analysis.

The reason for this statement lies in the fact that Mr. Elmont has overlooked the effect of the very uneven distribution of the reinforcement in the different parts of the panel area, and the influence which this has in causing a somewhat different distribution of stresses in the slab from what occurs in a uniform plate of metal. In particular he singles out for especial attention the positive bending moments that cause tensions in the material at the upper surface of the slab in directions perpendicular to the sides of the panels at their edges where there are no reinforcing rods to resist such tensions, and argues that ordinary flat slabs are unsafe for that reason.

I deny that such is the fact where the column heads are sufficiently stiff and strong, and say that the capacity of a slab for carrying loads is sot affected to any material extent by cracks in the concrete extending lengthwise of the edges at the top of the slab. Such cracks occurred, for example, in the test of the Deere and Webber Building in this city, which was built by a competitor of Mr. Turner, and the test reported in the Proceedings of the National Association of Cement Users for 1911, page 177, by Mr. A. R. Lord.

The reason why such cracks are unimportant is this: the construction of the slab is such that the important question is not as to just how the moment about the edge is distributed along the edge, but whether there is sufficient steel all told across each edge to resist the total stress. Stress which by plate theory occurs across the central portion of the edge of the panel is ordinarily transferred by twisting moments in the slab to the stiff heads of the columns. The middle portion of the side belts can yield to the positive moments across them to a very limited extent only (usually not enough for the formation of cracks) before resisting stresses in these heads are brought into play. This yielding, however, may and does take place without injury to the slab and without developing any real weakness in it. That such cracks and lack of steel to resist them are matters of no consequence is evidently the opinion of Professor Talbot, to whom Mr. Elmont refers as an authority on slabs, as appears from a passage which I quote from a discussion on flat slab floors, page 191 of the Proceedings previously referred to:

*By V. J. Elmont, B.Sc., in *The Canadian Engineer* of Sept. 25th, 1913.

†Reinforced Concrete Floor Slabs, by H. T. Eddy, published by Rogers & Co., Minneapolis, 1913.

"Mr. W. B. Phillips: In the floor under test, (of the Deere and Webber Building) was reinforcement provided at the centre of the span, at right angles to that connecting two columns at the side of the panel? I believe some reinforcement should be provided between the columns in order to take care of the reverse moment, eliminating cracks to which Mr. Lord refers.

"Mr. A. N. Talbot: In so far as I know, such reinforcement is not used in any of the girderless floors. The cracks referred to are minute hair cracks which, when the load is removed, will close up so as not to be visible. . . . . So far as any one knows, they are not detrimental to a structure."

This is the only point on which Mr. Elmont attempts to substantiate his general sweeping criticism and condemnation of flat slab systems.

But this is not a question that can be settled by quoting opinions or citing authorities. It is a question of fact and experimental verification. There are no observed facts whatever in support of any such stresses as Mr. Elmont computes. It is quite true that systems in which the heads of the columns are not sufficiently large and stiff might be amenable to the objections stated by Mr. Elmont, but when he attempts to excite general distrust of the stability and safety of the pioneer system of flat slab construction by saying that "to-day theoretical and practical experience will veto most of those early systems," he speaks without authority because he is not the possessor of any adequate theory, and is not supported by reference to the facts, which show that not only have such slabs satisfactorily passed the test of carrying twice the live load without failure, but have done this for months at a time without signs of distress; a kind of test to which no other form of structure could be safely subjected.

It may be an open question as to what should be regarded as a sufficient and satisfactory test of a given type of structure. But is would seem as though one which no other type of structure could equal should be so regarded.

There is one peculiarity of flat slab construction which makes it perhaps the safest type of structure which it is possible to erect, but it is a peculiarity not ordinarily recognized, viz., its toughness. It will not collapse, nor give way suddenly under any load that it is possible to place upon it. By sufficient over-load or by too early removal of forms, a flat slab may be made to bag downwards and do almost anything, except actually to fall. A gradual yielding without impairment of strength is the worst that can occur under over-load. Lack of recognition of this fact seems to be the background of the attempt here made to awaken distrust in reinforced flat slabs.

In my treatise on flat slabs, rational formulas have been established that agree closely with a large mass of observations on many different slabs made by various experimenters, the details of which are not there given. But the result of a numerical discussion of half a dozen of the most complete of these tests is now accepted and awaiting publication in the Proceedings of the American Society of Civil Engineers, which will entirely corroborate the statement just made as to the agreement between computed and observed values of both deflections and stresses. Mr. Elmont cannot cite any such agreement of his computations with observations, and until such agreement can be established he is not justified in asserting what will or will not happen to slabs whose entire behavior can be predicted by rational formulas.

My present opinion is that not only has Mr. Elmont drawn incorrect and unwarranted conclusions from the analysis he has offered, but has also seriously misunderstood and misrepresented the position of Professor Talbot when he refers to him as having shown "the insufficiency of reinforcing in flat slabs as ordinarily constructed."

I would respectfully ask Mr. Elmont either to substantiate this statement or to withdraw it. I have been unable to find any such thing in Professor Talbot's publications, but, on the contrary, much to make me think that he is quite unwilling to express the opinion that flat slabs constructed on the lines which Mr. Elmont condemns are necessarily unsafe.

Had Mr. Elmont been willing to point out types or specific instances of the kind of weakness which he depreciates, it would have been possible to agree or disagree with him in better spirit than is now possible, when he apparently intends to bring flat slabs in general into disrepute, and especially in case they are not reinforced across the top at the side belts, a view known to be so erroneous by all constructors of flat slabs, Professor Talbot included, as to detract very greatly from the weight that might otherwise be attached to any other views he might express upon the properties of flat slabs.

H. T. EDDY.

Minneapolis, Minn., Oct. 8th, 1913.

[A copy of Dr. Eddy's criticism was forwarded to Mr. Elmont, who furnishes the following reply.—Ed.]

Sir,—It was certainly not the intention in the writer's paper to bring flat slabs into general disrepute, and the writer has difficulty in understanding how Dr. Eddy could read that out of the paper. The writer considers the reinforced concrete flat slab as being a very economical and suitable structure for many purposes, and thinks that great credit is due to Mr. Grashof for his theoretical investigations, to Mr. Matrai for his reinforcing system leading up to the reinforced concrete flat slab, and Mr. Mensch for being the first—to the writer's knowledge—who employed a flat slab in an actual building.

The aim of the paper was to improve the present design of flat slabs. What the writer expressly directed his efforts against was mentioned in the following words:

"In nearly all flat slabs it is found that the positive bending moments and the negative moments over the columns are provided for . . . but the negative moments perpendicular to the sides of the panels are, as a rule, entirely neglected, although they have about the same numerical value as the maximum positive moments."

Dr. Eddy denies (1) the necessity of reinforcing against these negative moments perpendicular to the sides of the panels; (2) that Prof. Talbot's test loadings tend to prove this necessity.

(1) In his above writings Dr. Eddy refers to his book "Reinforced Concrete Floor Slabs." The writer obtained this book, thinking that it was a pure professional treatise, but found it to be mixed up with advertising matters for Mr. Turner's system. If nothing else, the writer had the surprising satisfaction of finding that Dr. Eddy not only arrived at the result that the above-mentioned negative moments exist, but that they have

far greater values than those given in his paper (though the writer disagrees with the procedure by which Dr. Eddy arrives at these high values).

In spite of this, to state that they do not need to be taken into consideration and resisted by reinforcement is rather strange. It must be granted to Dr. Eddy that so far no flat slab in reinforced concrete has failed on account of lack of this reinforcement, but at the same time, no well-trained structural engineer would consider this circumstance to be a proof that this reinforcement was unnecessary and neither is any proof contained in the fact that flat slabs, designed without this reinforcement, are able "to carry twice the live load without failure, and have done this for months at a time without signs of distress, a kind of test to which no other form of structure could be safely subjected." These last lines, quoted from Dr. Eddy's discussion above, together with the following lines

> "It may be an open question as to what should be regarded as a sufficient and satisfactory test of a given type of structure. But it would seem as though one which no other type of structure could equal should be so regarded."

certainly form the most astonishing engineering statethat the writer has ever seen in print.

First of all, it is not sufficient for an engineer to know that a structure is still standing carrying twice the live load; the important thing to know is how much greater load it would be able to carry without failing. Furthermore, the writer would like to show Dr. Eddy that there is nothing extraordinary when a flat slab carries twice the live load for such a period as "months at a time." That load is only a comparatively small percentage of what it ought to be able to carry before failing. Dr. Eddy might, perhaps, know that numerous very careful experiments have shown that reinforced concrete slabs, reinforced with the usual percentage and kind of steel, are able to carry at least three times the total load (live + dead) for which it has been calculated The load Dr. Eddy is so proud of is

$$P = 2 \times \textit{live load} + 1 \times \textit{dead load};$$
$$\text{or, } P = 2 \times p + 1 \times g;$$

but it should be possible to load these slabs—of course only when properly designed—with,

$$Q = 3 \times p + 3 \times g.$$

Taking $g = \frac{1}{2} p$, we obtain,

$$P = 2.5\ p,$$
$$\text{and, } Q = 4.5\ p;$$

thus P is only about 55% of what a correctly reinforced flat slab should carry before failing.

Dr. Eddy's statement that "no other form of structure could be safely subjected to a test load equal to twice the live load" is, in the writer's knowledge, incorrect; it seems to indicate that Dr. Eddy's design would not be effective beyond that test load. A remedy for this could no doubt be effected if Dr. Eddy were to adopt the reinforcement as advised in the writer's paper, and take the positive bending moment at the centre of the slab, as derived in the paper, to be about $\frac{Wl}{23}$, which is also close to the bending moment, given in the new building regulations for the city of Cleveland. The writer noticed on page 878, Vol. 24, of this paper that Dr. Eddy figures with $\frac{Wl}{50}$. It is also stated "that Mr. Turner's design is extremely light and seems somewhat daring when compared with designs made by other engineers.

(2) The test loading, conducted by Prof. Talbot, that the writer especially had in mind, was that in the Deere and Webber building, described fully in Bulletin 64 of the University of Illinois, published January, 1913, (Tests of Reinforced Concrete Buildings Under Load, page 88 and following). This test loading appears to the writer to have been carried through in a careful way and to be of unusual importance as it has been conducted in an actual building with almost the same exactness in studying the results as can be obtained in a laboratory test.

The floors were calculated for 225 lbs. for sq. ft.; at a test load of 350 lbs. per sq. ft. cracks appeared along the sides of the panels which plainly indicated the negative bending moments. These cracks are plotted in Fig. 75 of the Bulletin.

In conclusion, the writer would quote what Prof. Talbot says with regard to these cracks: "Another set of cracks (besides those about the column heads) which developed only under the maximum load of 350 lbs. per sq. ft. is significant. These cracks ran along the centre line of the cross bands, being easily traced in the portion about half way between columns, growing fainter towards the columns, and disappearing entirely in most cases before reaching the crack over the edge of the capital. Evidently there is negative bending moment at these sections. These cracks, we believe, had not been observed before, probably because other building tests have not been so extensive, and because cracks have not ordinarily been very carefully observed."

V. J. ELMONT.

Montreal, Que., Oct. 17th, 1913.

WIRELESS TELEPHONY IN BRITISH MINE.

An invention of Josef Heinrich Reineke, a system of wireless telephony, which has been installed in the Dinnington colliery, near Rotheram, has been found to give excellent results. The invention is used widely in Germany; and now that the British home office order for the installation of underground telephones in mines has come into force, an English company has been formed to work the patent, and the Postmaster's license to use the patent has been granted to W. Holmes, M.I.E.E. Its chief merit is that signalling can take place through solid rock over a distance of at least one mile. At the Dinnington colliery, stationary instruments are fixed at given points in the mine, and each station can communicate with any other station. In addition, each gang of colliers may be provided with a portable telephone, which can be brought into communication with the stationary telephones in case of need. A further advantage is that communication can be maintained from the pit head or the pit bottom with the moving cage. The apparatus is described as follows:—

"The instruments are exactly like those used in ordinary telephoning, consisting of receiver, transmitter and battery. The battery is of the dry-cell type, and has a life of three years. The portable instrument contains the same parts as the fixed one, and weights about twenty pounds. It is enclosed in a box, and can be carried from one part of the mine to the other. The instruments are fixed up like ordinary telephones, but instead of a wire connection two wires are connected from each instrument to some metallic substance buried in the ground. Connection can be made to the tramway lines in the pit or to water pipes or any convenient metallic substance in the workings."

ENGINEERING AS A PROFESSION

SOME CHARACTERISTICS OF THE ENGINEER AND OF HIS PROFESSION THAT ARE NOT GENERALLY KNOWN—EXTRACTS FROM AN ADDRESS TO THE UNIVERSITY OF TORONTO ENGINEERING SOCIETY, OCTOBER 15TH, 1913

By WALTER J. FRANCIS, C.E.,
Consulting Engineer, Montreal

ENGINEERING is such a material thing, such a practical thing, and such an engrossing thing, that it is very difficult to talk about it in the abstract. Moreover, the engineer is known as a man who does things, and one who is doing things is too busy to talk. You will, therefore, appreciate the greater difficulty experienced by one who is supposed to be an engineer talking in the abstract on such a subject as engineering.

In order that we may have some appreciation of the subject, it is necessary for us to arrive at some definite understanding of the two words "Engineering" and "Profession," although I cannot promise you that these definitions will entirely sweep away the mist.

"Professions."—We all have our ideas what a profession is, yet it might be very difficult for us to name many professions and, having named them, to state the reasons why they are professions. Probably the first of the professions that would come to our mind would be that of law, medicine and theology. Later we would add pedagogy, dentistry, architecture, and surveying. Some might even go so far as to add engineering. The predominating characteristic of all these callings is their protection by law and their recognition as lawfully constituted bodies by the powers that be and by the people themselves. The distinguishing feature of a profession is that it requires its members to have special training and to perform mental rather than physical labor. Custom has decreed that an individual member must earn his livelihood by his chosen profession. The representative society or societies of each profession have a written or an unwritten code of ethics. This code requires, amongst other things, that the remuneration received by a member for his services shall not be in any way contingent upon the result of his work, or, in other words, the professional man may not share in the profits. Thus, a lawyer may not, theoretically at least, accept a case on the understanding that he will be recompensed only in event of a victory over the opposing party, or a doctor may not perform an operation on the understanding that his fee will be greater if his patient should live than it would be if he should die. Further, the law recognizes, more or less, certain fees that must be paid in court for the services of certain professional men, the surveyor, for example. You will doubtless be pleased to learn that the law allows a surveyor six dollars a day for attendance at court, while engineers and other ordinary mortals receive one dollar and a quarter as an emolument for such service.

The standing of the professions in the popular mind is due largely to the character, ability and dignity of the men engaged therein.

The societies representing the professions are the result of the interest that the leaders of the professions have taken in order that the professions may be recognized as such by the world at large.

Generally speaking, a man is no longer considered a member of a profession when he ceases to earn his livelihood by the practice of the profession. A dentist leaving his calling to become a vendor of real estate is no longer considered a dentist, although he has had his training and may still be holding his diploma. A doctor may have received all his degrees and may have practised for decades, but let him devote his energies to commercially exploiting, say, some well-tried prescription, and the medical profession no longer recognizes him as a member. And so we see that the connection of earning that which is needful to purchase food, clothing and the necessities of life is intimately connected with the recognition of a person as a member of a profession.

"Engineering."—It is much more difficult to define engineering. What is an engineer? I confess I have been trying for twenty-five years to find out—and I am still trying. I remember two boys, now both on the list of graduates of this university, arguing about whether a civil engineer should know all about a locomotive or not. He thought he should. I didn't know. The other fellow is now practising surveying. Once I heard a judge of the Supreme Court of the United States struggle with the definition of an engineer in a brilliant twenty-minute speech, and he wound up by concluding that he didn't know anything definite about engineers excepting that they were jolly good fellows. In the daily press we often read of engineers, but before we get through the description we are fully aware that the person referred to drove locomotive No. 522 between two given stations at seventy miles an hour, or that he was the man who turned the throttle valve of the engine in the hold of the excursion boat.

The term "engineer" is very much overworked. It is not surprising that the great public gets confused in the multiplicity of engineers that are sometimes referred to. There are the civil engineer, the mechanical engineer, the military engineer, the electrical engineer, the hydraulic engineer, the sanitary engineer, the municipal engineer, the production engineer, the publicity engineer, the mining engineer, the chemical engineer, the structural engineer, the bridge engineer, the elevator engineer the harbor engineer, the stationary engineer, the government engineer, the city engineer, the town engineer, the tunnel engineer, the county engineer, the marine engineer, the railway engineer and the consulting engineer.

Mr. Dunn, the president of the American Institute of Electrical Engineers, in Boston last year referred to twenty-seven recognized classes of engineers, and I understand that someone of a statistical turn of mind has succeeded in isolating over one hundred and ten separate and distinct varieties of the bacterium *Engineerious Universalis*. Is it any wonder the public gets confused?

Compared with the professional men of law, medicine and theology, the engineer never comes to the at-

tention of the public as a learned man doing things. Let a man be a member of one of the other professions and as soon as he begins to accomplish things he will be heard of. Let a geologist make a speech on his chosen subject and the newspapers of the land will blaze forth with startling headlines that Professor Geologus has unlocked the great secrets which Mother Earth has hidden in her bosom for millions of years. Professor Haultain accounts for this by the fact that the geologist takes time to tell the people what he is doing and what he thinks he has discovered. Let the lawyer defend some celebrity, whether famous or notorious, and before many hours the whole world will know it and will be gazing upon indifferent pictures of that lawyer. It is, probably, safe to say that the engineer may devote his life to the service of the world and die doing his duty, and yet never be heard of during his career, unless he unfortunately make an error in judgment or a slip of some kind. I venture to suggest that Quebec Bridge was more widely known by its failure than it or any other bridge will be in its success. I do not know that the engineer cares particularly about publicity, for he is too busy doing things. I am referring now only to the recognition or non-recognition of his professional existence by the great public. Anyway, he is too busy doing things to stop for the sake of publicity. One of the powers that the engineer under-rates is the power of the press. Summing up, it would appear that the public has, at the best, a very hazy idea of what engineering is. Every engine runner of the country is an engineer, no matter whether he operates a locomotive or a threshing engine. Even the plumbers try to play on the title and have in our own country succeeded in getting an association incorporated under the name of the Canadian Society of Sanitary Engineers. All respect to the man who can wipe joints and collect his bills of world-famous magnitude, but it looks very much like trespassing on the dignity of the name of the great recognized engineering body of Canada, the Canadian Society of Civil Engineers. It is, indeed, a most fortunate thing that the motorman does not term himself a street car engineer, that the chauffeur does not call himself an automobile engineer, and that the aviator does not wish to be known as a monoplane or biplane engineer. I was just wondering, if the analogy were carried on, what the man would call himself who runs a wheelbarrow.

Engineering Societies and Engineering Defined.—There are in every country recognized engineering societies having for their object the betterment of the profession and the uplifting of its members, all of whom are required to have certain pre-requisites of training and experience. In Canada there is the Canadian Society of Civil Engineers, in Great Britain the Institution of Civil Engineers. In the United States the American Society of Civil Engineers takes a corresponding place with, however, the addition of very strong societies known as the American Society of Mechanical Engineers, the American Institute of Electrical Engineers and the American Institute of Mining Engineers. We have in Canada also the Mining Institute of Canada. In the constitution of the Canadian Society of Civil Engineers and of the Institution of Civil Engineers the art of engineering is defined, but, so far as I know, no definition is given by the other bodies I have named. The definition used by the Institution is that devised by Tredgold, well nigh a century ago. He calls engineering "the art of directing the great sources of power in nature for the use and convenience of man." The Canadian Society of Civil Engineers has based its definition on the same formulæ in the words "the profession whereby the great sources of power in nature are converted, adapted and applied for the use and convenience of man." With definitions such as these given us by two of the leading English-speaking engineering organizations, it is not surprising that the public has some difficulty in comprehending what an engineer really is; that is, assuming that these definitions ever reached the public. I think it may fairly be said that you could not be considered much of an engineer when you first learned to overcome the law of gravity and stood on end to direct that great source of power in nature to your use and convenience. It has truly been said that the greatest source of power in nature is the tongue of a woman, nevertheless, to your engineering ability could not be applied any other definition than that of "contriving" when you succeeded in getting your mother to persuade your father to buy your first rubber boots. We are told that this definition of Tredgold was primarily intended to distinguish the military engineer from the civil engineer. I think there might be some difficulty in endeavoring to apply Tredgold's definition of a civil engineer to the military engineer, because that military engineer would not find it easy to convince his enemy that the cannon balls were for the use and convenience of said enemy, even if there were any enemy left to argue with. Maybe my lack of soldier enthusiasm prompts the remark. The conflicts for the necessities of life are surely serious enough without adding other struggles blazing with uniforms, glittering with cold steel and reeking with blood. But we must not forget that in the olden days much of what is now known as "public work" was done under the direction of the military authorities who possessed the only complete organization of the time.

Professor Swain has perhaps unconsciously given a definition which, it seems to me, excels all others, where he calls engineering "the application of the laws of nature, the principles of mechanics and materials of construction to the business of the world." It seems to me that we have in these words a definition of engineering in its broadest sense.

Engineering Training.—This definition brings me right up to the present moment speaking to you as a body of young men who have entered one of the great engineering schools to learn something of how to apply "the laws of nature, the principles of mechanics, and the materials of construction to the business of the world." You have come to a great institution. Its graduates are to be found everywhere making good. Go from Tyrrell on the north to Laschinger on the south, start with Lash in Java and encircle the world, and you will find the alumni of Toronto. I myself am proud to be on the same list as Duggan, Stern, Thomson, Wright, Ross, Deacon, Mitchell, Fairbairn, Speller, Angus, Chalmers—I should not have started to name them personally, because they should be named by the hundreds —an honor list of which everyone should be proud. It has been said of Sir Christopher Wren in St. Paul's, "If you would see his monument look around you." I say to you, if you would see the monument of John Galbraith just look around the world at the engineering alumni of Toronto.

The definition necessarily implies broad-mindedness. You cannot be a good engineer and be narrow-minded. So, do not forget that this broad Dominion has other universities, older ones in the Old East and newer ones in the New West. Queen's and McGill are great universities. There are many great universities in the

States. England has a great number of the highest engineering schools in the world. So has France. Germany was well advanced with engineering training before some of the other countries began to be serious about it.

But your university training will not make you an engineer. It will equip you to become an engineer—if the engineering spirit were born in you. By hard work and the application of the training you will here receive you will, I trust, all become engineers.

You are now, doubtless, realizing the difficulties surrounding "engineering as a profession." Eliminating all those engineers who share in the profits of their labors, it will be seen that it reduces the number to a comparatively small number of men—small as compared with the number composing the profession of law or medicine. Yet, it cannot be said that those eliminated are not engineers. On the contrary, they are engineers in every sense of the word, and they are so recognized by all the great national engineering organizations. Many of the leading ship builders, bridge builders and contractors are amongst the best engineers of the world, and they have and are occupying the topmost positions of honor in the engineering world.

The idea of a part of the engineers taking a stand shoulder to shoulder with the other professions is growing fast. Already a powerful movement is taking place in this direction, and it is interesting to note here that the indefatigable secretary of the only really professional organization of engineers was a member of the class of 1884. I refer to Eugene W. Stern, secretary of the American Institute of Consulting Engineers. Let me, in passing, call attention to the pre-requisites of membership with these professional engineers. A member must be at least 35 years of age, he must be actively engaged in the independent practice of the profession, he must be a full member of one of the great recognized engineering bodies, he must have a high character, he must have attained a degree of eminence in the profession, and he must not be engaged in contracting. When you come to realize the requirements for admission to any of the great recognized engineering bodies and add to that all the other stipulations that have been named, you will see that the standard set up by the American Institute of Consulting Engineers is one of which the engineering world should be proud. The membership is jealously guarded and, of course, it is not great in numbers. At present I think there are less than 70. This organization illustrates to some extent the difficulties surrounding "engineering as a profession." One is forced to conclude that "engineering" is too great and too comprehensive to ever be confined within the narrow limits of a "profession" in the same way as law and medicine. As it looks at present, we should associate ourselves with the recognized engineering bodies first and, later, if our choice take us in that direction, the Institute of Consulting Engineers. In the meantime study the work that the Canadian Society of Civil Engineers is doing.

As I look at the whole question that there are in this world two classes of people, the producer and the non-producer. At the bottom of the non-producers I place the real estate men and the speculators. At the top of the producers I place the agriculturist and the engineer. Between these extremes live all the other callings, and I shall leave you, each for himself, to place them according as they may, in your judgment, be producers or non-producers. Under our present social system the agriculturist must come first, because we must have food and clothing. Next in order in the world's progress is the engineer. The Indian in his native state, the Arab with his caravan has no need of the engineer. The farther we get from the primitive the greater the need of those who are able to apply to our use and convenience the great sources of power in nature. The marvelous advances of the last century are engineering advances. The other professions are older than engineering. Art is centuries old, yet it is a question if the art of to-day is on the same plane as that of Greece and Rome centuries ago. The grandest examples of the work of modern architects are based on the ancient orders, and the advances of architecture in modern times are due to the engineer in introducing steel skeletons and reinforced concrete. In surgery wonderful progress has been made within a lifetime, but the skill of noted surgeons was developed only through the medium of the engineer's handiwork in fine instruments and electrical appliances. The physician heals the sick and deals with individuals, while the engineer holds in his hand the health of towns, cities and nations. The preacher has no particular use for the engineer excepting as illustrations in sermons. The lawyer lives on the engineer's quarrels and on the relations which by his ingenuity he has set up between others. The teacher helps to prepare the embryo engineer for his admission into a cold-blooded world and promptly forgets him in the future pursuit of embryology.

It is the engineer who harnesses the Niagaras of the world to transform the night of our cities into noonday and to turn the wheels of commerce. It is the engineer who develops the mining and furnishes the metal with which he builds machines that by their ingenuity compel us to stand in awe and admiration. It is the engineer who produces the steel to form a network of highways over our continents and that makes possible the myriads of floating palaces on our oceans. It is the engineer who has abolished famine and pestilence. It is the engineer who has annihilated distance with his telegraph and his telephone. It is the engineer who has made possible the conquest of the air. It is the engineer who places in the hand of the president of a nation the power whereby he is able with a touch to remove from a point thousands of miles away a barrier of nature separating two oceans. It is the engineer who furnishes the worker in the golden west with the machines whereby millions of bushels of wheat are each year made ready to enter the hopper that the engineer has constructed. It is the engineer who has made Canada of to-day what she is.

In concluding, Mr. Francis referred to the foregoing generalities as being accomplished by the summation of the efforts of individuals, and he impressed upon the members of the society the necessity of upholding the high ideals of the engineering profession.

RAPID DAM CONSTRUCTION.

Near San Antonio, Texas, a concrete dam 164 ft. high, and having a crest length of 1,580 ft., was recently completed in 12 months. It contained 300,000 cubic yards of concrete, and forms part of an irrigation scheme for an area of about 60,000 acres. It has a spillway 1,200 ft. long, which delivers into an adjoining ravine. The delivery of the water involved the use of semi-circular sheet-metal flumes, one of which was supported on towers for a length of 1,500 ft., the greatest height being 95 ft.

THE LEONARD LOCOMOTIVE AND CAR SHOPS OF THE NATIONAL TRANSCONTINENTAL RAILWAY AT QUEBEC, P.Q.

THE general layout of the repair shops of the National Transcontinental Railway at Quebec, P.Q., is such as to show that not only has convenience of operation been the general principle governing the design, but that future needs have also been provided for. Each shop is capable of extension without interfering with any other, and any department can be increased separately as occasion may require.

There are eleven buildings in all, of various dimensions, each suitably designed for the special work to be done in them. These buildings consist of a locomotive, erecting, machine and boiler shop, forge shop, freight car shop, power house, planing mill, dry kiln, lumber shed, forge stores and scrap bins, oil house, stores, and office building for the executive staff. The total area covered is about five and one-half acres. The locomotive, erecting, boiler and machine shops are all under one roof, and arranged as shown in the plan (Fig. 1). The building is 602 ft. 6 in. in length and 152 ft. wide. It is shown in cross-section in Fig. 2.

In the erecting shop there are eighteen pits, placed transversely, and over them a 120-ton crane operates, lifting locomotives into and removing them from, their respective positions. A 20-ton crane operates over the same area at a few feet lower level. It carries small material, and is designed for light and rapid service.

The transverse-pit layout has the advantage of doing away with many side doors in the building for the in-and-out movement of locomotives. There are two doors, conveniently placed, through which engines and material enter and leave. It will be noted that this arrangement is economical in the matter of heating. It dispenses also with the necessity of a transfer-table, with all its inconvenience from snow and ice. The practically unbroken side-wall permits the use of jib cranes, one serving the fronts of two locomotives, being capable of lifting smoke-stacks, main valves, smoke-box doors and rings, etc. The use of these very handy cranes would be most difficult if the wall of the shop had been cut up into a series of doors.

The cross-section of the shop (Fig. 2) shows the position of the cranes. The large crane is carried on a series of built-up columns, so that the heavy load is central over the line of foundations. As one crane does the work of lifting and placing each locomotive, there is no chance of confusion such as might occur when two cranes are used, and where two men do the work. The single powerful crane has also the advantage over the usual twin-crane arrangement in economy of first cost and maintenance.

All the overhead cranes are provided with effective safety appliances. One of the most important of these appliances prevents the load from being "over-wound" by the lifting-drum. It consists of a device which, when the maximum lift has been reached, automatically opens a switch on the hoisting circuit, thereby cutting off the current, and suddenly removing the driving power. The cessation of the current immediately brings into powerful action a gravity-operated brake, which is normally held out of service by the flow of current.

The direction in which the midway crane operates is a new departure in railway shop construction, and substantial advantages are secured. The midway is laid out so as to be alongside of the shops, and not at the ends of the buildings, as is frequently the case. The object

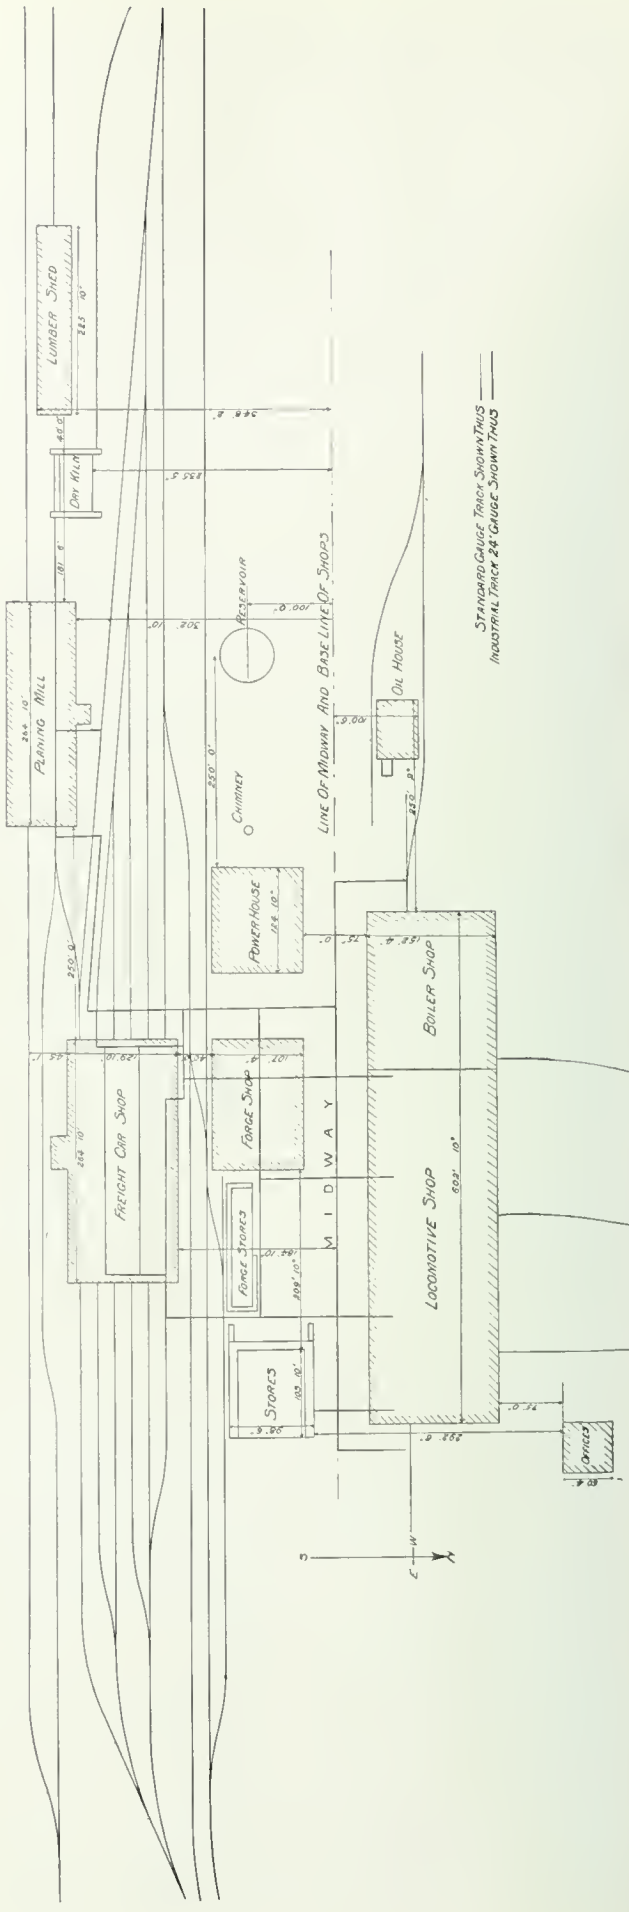

Fig. 1.—General Plan of the Leonard Locomotive and Car Shops, Quebec.

of this arrangement is that when material is brought by the midway crane from the storehouse, forge shop, or foundry to the machine, erecting or boiler shop, it is placed at the door nearest to the machine on which the material will be handled, or to the engine upon which it will be used. In this way the delivery of material is not concentrated at one spot at the extreme end of the building. It avoids distribution from a congested area, and it obviates long haul through the shop. Material is laid down at a point as near as possible to its destination, and economy of time and labor, as well as facility in handling, is thus secured.

The system of placing machines is such that the movement of material will be in one direction, and the distance over which any locomotive part is carried will not be unnecessarily lengthened by journeys forward from one machine and back to another. The continuous one-way movement of material saves time and labor and prevents interference.

The pits in the locomotive shops are supplied with steam, compressed air, hot and cold water. Depressions in the pit walls carry the pipes. By this arrangement the working space in the pits is not restricted, and the pipes are not where they can be easily damaged by workmen dropping material on them; and thus while being quite safe, they are out of the way.

The forge shop and the boiler shop are placed as near as possible to the power house. This is important, for in the case of the forge shop, where hammers are operated by live steam, the short distance between boiler and hammer reduces condensation and delivers steam where it is required with small loss. A similar condition holds good in a sense, for the delivery of compressed air to the boiler shop machinery. The nearer the source of supply, the less the pipe friction involved and the smaller the losses due to the forcing of air through the pipes.

Industrial tracks form convenient means of communication between the various shops. The buildings, cars, engines and supplies are protected by a water-system arranged to be readily put in use in case of fire. A further protection is afforded by reason of the use of concrete and steel in the various structures.

The shops are situated at Quebec, and have been named after Major R. W. Leonard, chairman of the National Transcontinental Railway Commission, under whose administration they were projected. The outlay has been carefully supervised, so that excellent results will be attained and full value received for the money expended. The permanent and substantial character of the shops and the size of the plant will be of material advantage to the city of Quebec, by providing steady employment for

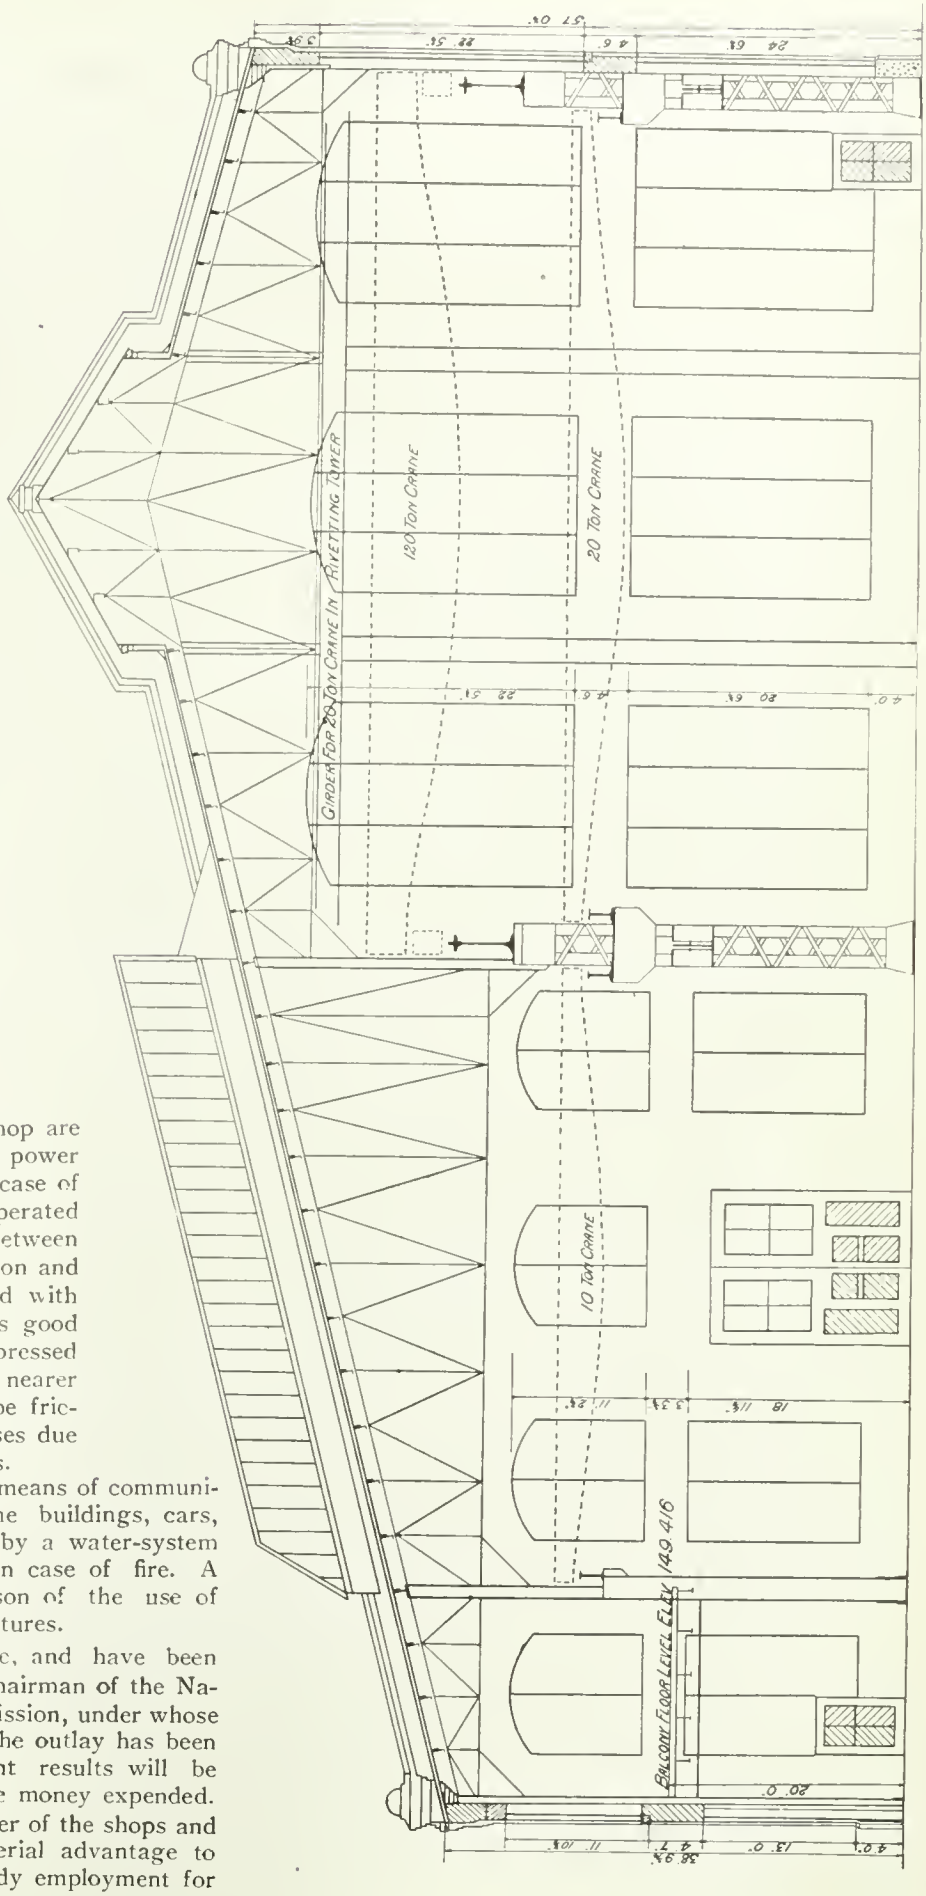

Fig. 2.—Cross-Section of Locomotive Shop—National Transcontinental Railway, Quebec.

a considerable number of men the year round. The whole plant has been laid out in such a way that the latest and most modern railway practice has been provided for, and the design will be second to none in the country.

The plant has been laid out under the supervision of Mr. Gordon Grant, Chief Engineer. The design of the plant, the relative size, arrangement and position of the buildings, together with the selection of the machinery and appliances, has been entrusted to Mr. W. J. Press, Mechanical Engineer, who has had charge of similar work at the Transcona Shops of the National Transcontinental Railway, which are now being operated, and which, in general plan and in kind and quality of equipment, are of the most up-to-date type. The Transcona and the Leonard Shops (when the latter is completed) will embody the latest design and the most modern practice, enabling them to be operated with a very high degree of efficiency. Altogether they will form a most valuable addition to the second of the great National "cross-continent" highways of Canada.

The contract for the construction of the shops was recently awarded to Mr. Joseph Gosselin, of Pt. Levis, Que., and construction work is under way.

A NEW CHEMICAL INVENTION.

While Mr. Henry S. Blackmore, one of the most distinguished chemists of the United States, was in Ottawa, he claimed that he had perfected a process of not only liquefying, but also of solidifying natural gas, and that either the liquid or solid could be used as a motor fuel. The fluid is ethereal in character, like gasoline; and from 8 to 10 gallons are produced from 1,000 cubic feet of gas. This fluid has the advantage over gasoline both in that it can be produced at a first cost of two cents per gallon, and in that it leaves no carbon deposit to clog the cylinder. In the form of a solid, a cubic foot of the fuel weights about 5 pounds, and comprises the condensed product of 2,500 cubic feet of natural gas. It has the appearance of crystallized paraffin, softens to putty-like consistency at 212 degrees, and at 312 degrees turns to gas again. The solid also is superior to gasoline in that a cubic foot of it will carry an automobile 12 to 15 times as far as a cubic foot of gasoline, and in that the solid as well as the liquid is safe to handle. Interests controlling the inventions of Mr. Blackmore have secured large gas fields in the United States and in Canada, and will manufacture this motor fuel at 10 cents per gallon or less; and natural gas in blocks will be shipped from the wells to the consumer.

WIRELESS RESEARCH.

The International Wireless Company has decided on the organization of committees in all the countries adhering to the wireless telegraph treaty, which was signed at London, in July, 1912, to aid the governments in extensive wireless observations and experiments. These will be carried out with the object, first, of determining a way to insure constancy and steadiness of wireless waves; secondly, measuring the variations in the signals and atmosphere disturbances at the different stations; third, comparing the intensity of the signals. These experiments will be conducted simultaneously on three days of each week, beginning in January. Special meteorological observations will also be made once a month. Reports of the work of the committees will be made to the wireless conference at Brussels in 1914 with a view to legislation.

THE MUNICIPAL ENGINEER AND PUBLIC HEALTH.

THE variety of problems that arrange themselves under the heading of "Duties of Municipal Engineers," is constantly being added to, and each unit continues to expand. Those which have to deal with public health were summarized by Mr. J. Antonisen, superintendent, Brandon Municipal Railway, in a paper which was read at the Public Health Congress in Regina some weeks ago. The subject was dealt with without effort toward comprehensiveness, but included those items only that fall within the borders of the engineer's work toward the establishment of a healthy community. According to Mr. Antonisen, they constitute the following lengthy list: A pure, plentiful water supply; proper sewage system; effective drainage system; well-organized system of collecting and destroying the garbage; sanitary lighting, heating and ventilating system for our public buildings and private houses; development of power to operate our public utilities and factories; cheap and safe means of transportation, both by urban and interurban and the larger railroad lines; proper construction of highways, roads, pavements and sidewalks; efficient maintenance and cleaning of our streets; proper city planning; liberal provision for park areas in our congested cities, and for playgrounds, public baths, comfort stations, and a hundred other items, which all come within the scope of the engineer's duties.

Of these, the first several are prominently important, and are dealt with by Mr. Antonisen as follows:—

Water Supply.—When the pioneer goes into unknown regions to find a new home for himself, his first problem is: Where can water be obtained for all kinds of domestic purposes? He locates his house near a lake, a river or a creek, and when other settlers follow, they ask the same question with respect to water supply. It is, therefore, not purely accidental that the majority of villages, towns and cities are located near rivers and lakes.

The pioneer's cabin becomes surrounded by settlers' houses; in course of time a village or small town grows up, and the community is gradually confronted with all the problems which have just been enumerated. At first the so-called practical men try to solve these questions, but sooner or later in the development of each town, the time comes when it becomes apparent to everybody that the state of things bespeak the need of an engineer.

By advertisement or by application to some large city a number of candidates for the position are obtained, and after due consideration the community selects their county or town engineer, who is then expected, for a salary of $75 to $125 per month, to be an expert in all branches of civil engineering. Thus the average town engineer puts up a bold front, commences to lick things into shape and, although he makes many daring leaps into darkness, he generally lands on his feet. By constant hard work and diligent study, seeking advice and information in engineering literature and from more experienced colleagues, he gradually develops into that modern wizard—the city engineer. During his development period he has laid out systems for waterworks, sewerage, built sidewalks, streets, bridges, subways, sewage disposal plants, reservoirs, water towers, dams, incinerators, grandstands, race tracks, and a thousand other things.

As long as the town is small it is contented to pump the water from a river or lake and using it without any

kind of treatment; it is considered all right to discharge raw sewage into the creek or river or lake, as long as the waterworks intake pipe is up-stream and the sewer outlet down-stream; or, in case of a lake supply, a couple of miles apart; but when the death rate rises up to uncomfortable figures, then the first question asked is: Have we got a pure water supply? The overworked, busy city engineer has worried over this question in idle moments, between midnight and sunrise generally, and has, perhaps, formed an opinion of what steps should be taken to safeguard against contamination of an existing pure supply, or procure a better supply than one already contaminated. Sound advice to the city engineer is: Get your council's permission to employ a consulting engineer of known repute; lay all your information, together with your own opinions, before him, and then let him decide what should be done. It is well-spent money to employ the consulting engineer, and when he has worked out the project, and it proves a success, give him the full credit for it, although you have furnished him with some useful information; because, if his scheme does not prove an unconditional success, he gets more than his full share of the blame.

Sewage Disposal.—Once a pure water supply has been secured, the engineer must turn his attention to the sewerage system, as this problem is of equal importance to the public health; not alone in his own town or city, but to all the inhabitants of the drainage area further down the stream or bordering upon the lake into which the sewage is being discharged. It was considered sufficient once upon a time to discharge the sewage raw into a flowing stream or a fairly large lake, and then trust to Nature for the rest; but Nature fails to respond to our trust, and we engineers are obliged to erect sewage disposal plants, a better name for which would, by the way, be sewage treatment plants.

This treatment of sewage in such a manner as to render it harmless is probably the greatest problem of modern engineering authority, and one that should not be tampered with, because a poorly or wrongly designed plant is worse than no plant at all. The province of Saskatchewan is to be congratulated upon the way in which this important problem is being dealt with. The Provincial Government has very strict rules regarding this subject. They employ their own experts, whose advice can always be obtained in designing a system, the plans of which must be approved by the government.

In connection with this matter there is one feature which could possibly be made a subject of recommendation to the government, and that is the operation of these plants after they are installed. No matter how scientifically a plant is designed, nor how properly it has been constructed, if a properly trained and enthusiastic man is not placed in charge of the operation to take proper observations of the results and see that proper results are obtained, the plant will be a dismal failure.

The conviction forced itself upon me, while city engineer in Moose Jaw, that the government ought to place a scientifically trained person in charge at each plant and contribute a portion of the cost of his salary as well as the cost of an experimental station, so that complete and reliable records could be obtained regarding the operation of the different plants.

Garbage Destruction.—Assuming, now, that an ample supply of pure water has been secured, and that there is in operation a plant where the sewage is being treated so successfully, that it ceases to be a menace to the public health. The system of collecting and destroying garbage is another important question. It is not exaggerating to claim that inside the limits of every city in Canada there are always hundreds of tons of garbage lying in a more or less advanced state of decay with the resulting dangers to children and adults. The air is poisoned by the emanating odors, but in spite of all this some cities are very careless and indifferent towards the garbage problem.

Here is a broad field for the engineer to organize a proper system of collecting garbage regularly and then also destroying it properly. When a town has grown to a size of 15,000 inhabitants, it can afford, and should erect, a garbage destructor which, when properly constructed and carefully managed, can be operated at a reasonable cost. The incinerator, which was erected during my stay in Moose Jaw, cost about $45,000, and had a capacity of 50 tons per 24 hours. It was operated without the use of any coal and developed enough steam for 50—75 h.p.

The most essential problem in connection with garbage is, however, to educate the public to co-operate with the authorities by reducing the garbage to a minimum, instead of having an abundance of barrels and boxes in the back yard filled to overflowing. There is no reason why the average household could not dispose of most of the garbage in the ordinary stove and furnace; the ashes can and should be kept separately and used for filling purposes; tin cans, when emptied, should be rinsed with water and then put on the bonfire, where it is permitted to have bonfires.

My attention has lately been called to a water-heating garbage burner, which is manufactured in Kewanee, Ill., and can be installed in ordinary private houses for from $150 to $250. It is claimed for this apparatus that it will destroy all house garbage and develop sufficient heat to provide hot water for domestic purposes. The municipal engineer should investigate such matters, and advocate their introduction in hotels, boarding houses, large private and public institutions, hospitals and asylums.

In smaller cities, which have not reached the stage where they can afford incinerators, the nuisance ground flourishes, and is generally very badly managed or not managed at all, but simply left as a perfect Gehenna. There is no necessity for such a state of affairs, as a nuisance ground, under proper management, can be made a smaller pestilence than at present by the display and use of common sense.

Fires should be maintained; a system of ditches should be dug, into which garbage that can not be destroyed in the fires can be dumped and afterwards covered with the excavated earth. On the average nuisance ground we can generally find enough combustible material, in shape of paper, rags and boxes, to maintain fires which will burn most of the garbage, or at least disinfect it, and in charge of the place are some old fellows who have been given that job because they are old ratepayers.

City Beautification.—But let us turn away from all this and consider the more pleasant tasks of the engineer, through which he promotes the comfort of his fellow-citizens and beautifies the city. These comprise matters such as building sidewalks, curbs, pavements, boulevards, parks and tree-planting. It is of comparatively small importance whether the sidewalks are laid at the property line or at the curb, as far as the public health is concerned; the main thing is to get a network of sidewalks

built so that the citizens can come back and forth from their homes without walking in ankle-deep mud, which is then dragged into the house. Dirt in every shape and form is a menace to health.

The boulevards should be made as wide as possible and trees planted thereon, as grass and trees have a beneficial effect upon the health of the inhabitants. A paved street is easily cleaned, as it can be swept with brooms and flushed with water, so that the dust and dirt can be removed into storm sewers or by street cleaning wagons.

No city can have too many parks and open spaces, as long as these can be provided for, while the land is cheap. The town engineer has to examine all plans of subdivisions, and he can often induce the owner of subdivisions to set aside a parcel of land for public parks and also get them to make some of the streets wider than the usual 66 feet. Provisions like these may seem unnecessary at the time, when the subdivision plans are submitted, but they prove themselves of great value to the public health when these districts become settled.

The roadways in residential sections of cities should be made as narrow as possible, just sufficient for the light traffic, as they produce dust and dirt, which is blown into the houses, whereas boulevards with grass are always clean, healthy and beautiful, when well kept.

As long as the town is small, the transportation problem does, of course, not signify, as the distances between residential and business sections are short, but when the land becomes very valuable, due to the progress of the city, and therefore the working classes must move away from the vicinity of their working places, then arises the necessity for rapid and cheap transit, and we build our electric street railways, which enable the man of moderate means to make his home in the outskirts or suburbs of a city, where land can still be bought or houses rented for a reasonable price.

The man who works in an office, shop or factory the whole day, needs change of air, when he is through with his day of labor, and the street cars, elevated and underground railways, as well as the steam-operated suburban trains, carry the working population back and forth between their places of work and their healthy homes at a small cost. We extend the water and sewer mains, electric light and telephone lines to the farthest limits of a city, so that there should be no excuse for overcrowding in tenement houses.

And when a city has reached the stage where this housing problem becomes an acute question, then we commence to talk of city planning, and we discover all the mistakes which have been made while the city was growing. And why were those mistakes made? Principally because the municipality had no power to control the city planning, and then, also, often because even though the authorities of a city had power to control the city planning, the engineer's advice was not obtained, but private interests dictated the policy of the controlling bodies.

This branch of engineering, the city planning, should be taken up more thoroughly by municipal engineers, because generally the town engineer has to pass all subdivision plans, and if he does not take a look into the future before passing a plan, it is pretty certain that nobody else will; and thus occur many blunders which it afterwards costs enormous sums to rectify.

The proper way is to let the city engineer lay out a city plan and then make property owners conform to this plan. That may appear autocratic to the free citizen of the new world, whose idea of liberty is often that he should have the right to disregard the rights of the community for his own personal advantage, but true liberty exists when law and order is most respected.

NEW DEPARTURES IN TELEPHONE.

An article in the *New York Telephone Review*, entitled "From a Limousine to the Depths of a Coal Mine," describes two types of special telephone equipment—e.g., a chauphone, or telephone for automobiles, and a special portable telephone equipment used in mine rescue work. The chauphone, which consists of a hand transmitter for the passenger connected to a loud speaking receiver at the chauffeur's ear, obviates the difficulties of speaking-tubes for automobile use. The mine rescue equipment has a special type of transmitter known as the "throat transmitter," since a man wearing an oxygen helmet which covers his month cannot use the ordinary type of telephone transmitter. The throat transmitter is light and compact, and is provided with a soft rubber cap, which adapts itself to the curves of the throat. The telephone equipment used by the men outside the mine or at the directing end consists of a chest-type transmitter and head-band receiver. The two are connected by a small wire cable, in 500-foot coils, carried in a leather case and fastened to the helmet man's belt, which pays out as he advances.

CANADA AND HER PAPER MANUFACTURING INDUSTRY.

When the Senate of the United States passed the Tariff Bill and removed the suggested countervailing duty of $2.00 per ton on chemical wood pulp manufactured in Canada, it threw open the gates of the United States to the wood pulp industry of Canada. The United States requires about 4,500 tons of paper daily, New York alone using 600 to 800 tons; and her wood pulp forests are fast disappearing. Her water powers not only are decreasing, due to the bareness of the hills, but are more valuable for other commercial purposes than for driving paper mills, that are very much inferior in supply of material and in limitation of power to competing Canadian establishments. For Canada is extremely fortunate in the possession of those three requisites underlying the manufacture of paper—i.e., cheap and abundant water power, cheap and contiguous wood supply, and ready transportation. And the United States has found that its manufacturers can no longer compete successfully in this business. Since 1911, when not more than 440 tons of paper per day were manutured, there has been an increase in capacity of 1,055 tons per day; so that up to date the total capacity of Canadian mills is 1,495 tons daily. At present the total production of United States mills is about 4,000 tons per day; but the increase of production in 1912 in the United States was 235 tons per day as compared with 430 tons per day in Canada; in 1913 up to date, 110 tons in contrast to 225 tons, which by January 1, 1914, will have been increased further by a capacity of 390 tons per day. Thus, whereas in 1909 and 1910, the capacity of Canadian mills was but 12 per cent. of that of United States mills, in 1914 the Canadian industry is substantially 40 per cent. of the American industry. So, for the interests of the republic, it was not a time to have restrictions placed upon Canadian wood pulp; and as far as Canada is concerned, the new tariff has meant the opening up of new towns in her backwood forests, and the great development of her lumber industry. Canada has taken precedence, because, in the words of Senator Weeks, of the United States Congress, "Canada is in a better situation to make the products which are absolutely necessary in this paper age of the twentieth century."

COAST TO COAST.

Edmonton, Alta.—Premier Sifton made the statement in the Provincial House on October 22nd that the Government will expend next year about $2,000,000 in telephone extensions.

Ottawa, Ont.—A West End Ratepayers' Association has been formed with the prime purpose of securing drainage for the district west of Rosemount Avenue, a matter which has been delayed for some time, much to the disadvantage of this section.

Vancouver, B.C.—The city solicitor has been instructed by Mayor Baxter to bring before the Railway Commissioners the matter of commencement on the C.P.R. tunnel from its west end reserve to the waterfront to obviate the great inconvenience to traffic.

Sutherland, Sask.—The program of civic works for which some time ago the ratepayers approved by-laws amounting to $200,000, will be commenced in its entirety early next season. However, grading operations on the thoroughfares is now in progress.

Vancouver, B.C.—The C.P.R. has presented to the city board of works plans in connection with the proposal to take over the railway reserve, which has become a warehouse district. But action upon these has been deferred until more comprehensive plans are produced by the railway.

Coquitlam, B.C.—A syndicate of Fort William, Minneapolis, and Winnipeg capitalists has selected Coquitlam as a grain elevator site. The head of the syndicate is Mr. J. H. Henderson, of Fort William, formerly head of the Grain Growers' Association elevators of that city.

Lethbridge, Alta.—The inefficiency of the Lethbridge waterworks system is shown in the report of City Engineer Harvey for the month of September. The report says that the city waterworks system sprang a total of 45 leaks, and this is a great increase upon the leakage of previous months.

Hamilton, Ont.—To endeavor to eliminate neglected features in connection with civic works in Hamilton, Alderman Byers is advocating the appointment of a works commissioner, who will closely inspect all works and conduct a cost system in connection therewith, and who will furnish a report weekly, or more frequently, to the city's board of control.

Vancouver, B.C.—Alderman Black, chairman of the civic water committee, has been considering with the water rights commissioner of Victoria the question of securing additional water supply for Vancouver. His desire is to obtain from the water rights and forestry departments of the Government full information in regard to the question of supplying additional water facilities from Seymour Creek.

Montreal, Que.—The firm of investment bankers, Nesbitt, Thompson & Company, of Montreal, have recently purchased $600,000 of the limited preferred stock of the Dominion Power and Transmission Company, Limited. This investment is a recognition of the important position the Power Company has taken and maintains in Hamilton and the surrounding territory.

South Vancouver, B.C.—A deputation from the Main Street Improvement Association has asked the Richmond Municipal Council to assist the association in its campaign to obtain the Main Street bridge across False Creek for the north arm of the Fraser River. The proposal is to remove this bridge from False Creek when it has been filled in, and when a sea wall 300 feet west of the bridge has been completed.

Victoria, B.C.—In connection with the construction and plans of the C.N.P. Railway's bridge across Selkirk water, Alderman Gleason has objected to the proposed pile structure across the beautiful waters of the Arm, and considers that at least a steel bridge should be erected. The council finally adopted a motion made by the alderman to leave the matter with the engineer and solicitor to bring the subject to the attention of the Canadian Northern representatives.

Toronto, Ont.—The new Danforth Avenue civic car line in Toronto has been duly opened with a formal ceremony and with evening illuminations, music, and processions in carnival dress. Those taking part in the official ceremony were Miss Hocken, daughter of the Mayor, the Mayor, and several of the city's aldermen and controllers. A dinner was served later in Playter's Hall; and a meeting was held in Riverdale rink, at which speeches were given by Hon. Dr. R. A. Pyne, Hon. A. E. Kemp, and Geo. S. Henry, M.P.P.

Vancouver, B.C.—The board of works for Vancouver has approved the plans of the southern approach to the Second Narrows bridge, and these have been placed before the Railway Commissioners at their sitting here on October 27th. The site of the approach was moved some sixty feet east, but the general location of the railway line was approved, subject to the bridge company's consent to construct retaining walls, and the necessary subways and bridges. The city engineer was authorized by the board to sign the plans upon these conditions.

Port Arthur, Ont.—The most modern elevator in the entire world, the new government elevator at Port Arthur, is now receiving the finishing touches to its construction. The contractors, the Barnett & McQueen Company, are still in charge of the contract, not having handed the elevator over to be operated under the government's control, nor will it be turned over until completed in every detail, which will perhaps not be for two or three weeks more. Although grain is being unloaded for storage, the full capacity of the big plant will not be called upon until such time as all the last bits of machinery are installed.

Fort William, Ont.—It is reported that the big Stanley Avenue sewer is nearing completion, and under favorable conditions will be finished this year. The open trench work running from the Kaministiquia River to a point 700 feet east of the Canadian Car and Foundry Company's plant was to be completed in October; after which, 300 feet of pipe will be laid under the car works, through which a tunnel will be run if possible. The trench has been built through a heavy loam and blue clay, and the workmen have experienced great trouble with water oozing into the cut when it had been dug to a certain depth. The entire length of the trench had to be shored up with long planks to keep the sides from caving in.

Elmira, Ont.—On October 29th the Hydro-Electric power was turned on in the skating rink at Elmira by Reeve I. Hilborn, and in the evening the current for the street lights was turned on by the Hon. Adam Beck. Delegates were present from all neighboring municipalities, and a band was in attendance to give the event an enthusiastic celebration. Many formal proceedings presided over by Reeve Hilborn, notably a "Made-in-Elmira" exhibition, were conducted by the municipal officials, and were lauded by the congratulatory speeches delivered by the guests of the day. A 250 horse-power current has been thus inaugurated in this enterprising village of a population of 200.

Peterboro', Ont.—At Peterboro', a street lighting system in connection with the Hydro-Electric system has almost been completed. Iron poles and brackets are now in position to support the magnetic arc lamps, which will be assembled in the course of a few days. There is, however, difficulty

arising in connection with the securing of a supply of electrical energy with which to operate the lamps. The present existing contract for the supply of power to the city by the Peterboro' Light and Power Company expires at the close of the present year. In the meantime the Power Committee of the City Council anticipate the successful issue of the expropriation proceedings which have been instituted with a view of obtaining civic control of a stated portion of the company's system in accordance with a special Act enacted by the Ontario Legislature.

Montreal, Que.—President W. G. Ross, of the Harbor Commissioners, in company with Lieutenant-Colonel Labelle and M. P. Fennell, assistant secretary, have made recently an inspection of the grain-handling facilities at Buffalo. As a result, Mr. Ross is advocating strongly that further terminals and grain-handling facilities at Montreal, and the improvement of this city's canal system must be undertaken as a national duty, and the national prestige of handling Canadian business through Canadian seaports, instead of allowing Canada's trade to be taken care of by United States ports, must be preserved. To keep pace with the demands of the development of the Canadian West, and of the increase in trade which will be brought with the completion of the Erie Canal, Buffalo is contemplating the erection at once of several new elevators. For like reasons, improvements are being constructed in connection with the trading port of that city.

Victoria, B.C.—Since the first of the month exceptional progress has been made on the Sooke Lake waterworks scheme, especially on the construction of the dam at Humpback Reservoir and of the dam and head works at the lower end of Sooke Lake. And Engineer Rust expects, that with favorable weather conditions the concreting of both localities will soon be completed. At Sooke Lake, the arrival of the four large metal gates which are to be placed in the gatehouse in such a manner as to permit of the entry of lake water at various levels, is expected daily, and the installation of these will be carried out immediately. Moreover, a start has been made in laying the temporary railway line along the right-of-way from the lake works to the point on the flow line grade above Cooper's Cove, Sooke Harbor, whence the concrete pipe lengths for the flow line will be carried to the pipe line grade by inclined railway and thence distributed by railway along the grade. At Humpback, early in November, the work will be almost completed as far as the city intends to carry it by day labor, and will be ready for the call of tenders for concrete flow line and steel pressure pipe line.

St. John, N.B.—The water distributing system of St. John has undergone a splendid improvement during the past year. The renewals in the water mains covering a very wide area of the city are a necessary supplement to the increased supply and pressure obtained through the new supplying main which was laid to Loch Lomond a few years ago. The great increase in supply and pressure available through the supplying mains was in some sections of the city unavailable owing to the deplorable condition of the distributing mains. These mains have been renewed in the city this past year to the extent of 11,410 feet of 8-inch iron mains; taking the place of mains which ranged in size from 1 inch up to 4 inches. The mains which have been replaced were practically all blocked up to a considerable extent by the corrosion of the pipes. The expenditure on the renewals amounted to $30,000. The department has prepared for a comprehensive scheme of supplying Lancaster and the West side by means of a 20-inch main, which will be laid across the new bridge at the falls. About 2,000 feet of new 12-inch water main has been laid from the Riverview Park out to the bridge. This main will be connected with the Strait Shore main, and both mains will feed the extension across the new bridge. The level of Spruce Lake is only a few feet above the level of Lancaster, and the water supply in this section is hardly adequate, and in view of the rapidity of the growth of that section will become increasingly inadequate. The level of Loch Lomond is sufficiently higher than Lancaster to give an efficient water service there. There will also be the advantage of two sources of supply.

PERSONAL.

DR. FRANK D. ADAMS, Dean of the Faculty of Applied Science, McGill University, Montreal, has been elected an honorary member of the American Institute of Mining Engineers as one of the 20 honorary members of that organization.

A. C. D. BLANCHARD, B.Sc., M.Can.Soc., C.E., formerly city engineer of Lethbridge, Alta., has accepted an appointment to the engineering staff of the Greater Winnipeg Water District. Mr. Blanchard assumed his new duties a few days ago.

T. C. KEEFER, C.M.G., of Ottawa, a past president of the Canadian Society of Civil Engineers, and of the American Society of Civil Engineers, and a member of the Institution of Civil Engineers of Great Britain, was recently elected by the unanimous vote, an honorary member of the American Society of Civil Engineers. When president of that society, Mr. Keefer experienced the distinction of being the first to hold the office, who was not a citizen of the United States, and the society has further extended this honor in the above way. Mr. Keefer is well known among engineers. He has been connected in the past with many of the most important engineering problems of Canada, being as a student the winner of Lord Elgin's prize on "The Railways of Canada," and being one of the first to advocate the construction of the Transcontinental Railway 50 years ago. Mr. Keefer, for a number of years, held a professorship in engineering at McGill University.

OBITUARY.

GEORGE CROFT, contractor, who was putting in the concrete work in connection with the harbor development at Cobourg, Ont., met death on October 29th, by accidental drowning. Mr. Croft was a brother of C. E. Croft of the R. and O. Line, and of Harry Croft, superintendent of government work at Cobourg.

COMING MEETINGS.

UNITED STATES GOOD ROADS ASSOCIATION.—Convention will be held at St. Louis, Mo., November 10th to 15th. Secretary, J. A. Rountree, L021 Brown-Marx Building, Birmingham, Ala.

NATIONAL MUNICIPAL LEAGUE.—Annual meeting will be held in Toronto, November 12-15. Secretary, C. R. Woodruff, 705 North American Building, Philadelphia, Pa.

AMERICAN ROAD BUILDERS' ASSOCIATION.—Tenth Annual Convention to be held in First Regiment Armory Building, Philadelphia, Pa., December 9th to 12th. Secretary, E. L. Powers, 150 Nassau Street, New York, N.Y.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS.—The annual meeting will be held in New York, December 2nd to 5th, 1913.

ORDERS OF THE RAILWAY COMMISSIONERS OF CANADA

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for small fee.

20648—October 22—Authorizing Twp. Saltfoot, Co. Wentworth, Ont., to construct and maintain highway known as 'Cochrane Road' across T.H.&B. Ry. in Lot 34, Con. 4, Tp. Saltfleet, Ontario, at its own expense. 2. Refusing application to construct highway known as 'Rosseay Road' across said Railway.

20649—October 23—Authorizing C.L.O.&W. Ry. (C.P.R.) to take certain lands for purpose of carrying out diversion of road allowance in Lot 34, Con. 8, Tp. Camden, Co. Lennox and Addington, and removing ground on north side of Co.'s right- of-way, in order to provide a non-obstructive view from said road allowance towards west as far as crossing of Bay of Quinte Ry. by C.L.O.&W. Ry. for a distance of 105 feet from said crossing, in accordance with provisions of Order No. 18696, dated February 13th, 1913.

20650—October 23—Authorizing C.P.R. to change present grade crossing in road allowance between Lots 24 and 25, Con. 3, Tp. Scarborogh, Co. York, Ont.; and construct additional track across said road allowance, at mileage 87.9 on Co.'s main line.

20651—October 23—Authorizing C.P.R. to construct road diversion in Lot 32, Con. 1, Tp. Scarborough, Ont., and to construct its tracks, by means of grade crossing, across said diversion, at mileage 90.4 on its main line, Toronto Subdivision.

20652—October 23—Approving location C.P.R. station at Lonsdale, Lot 23, Con. 2, Tp. Tyendinaga, Ont., at mileage 63.87 from Glen Tay; provided whenever it so develops that traffic on highway is blocked for more than 5 minutes at any one time by reason of location hereby approved, Board shall be at liberty to relocate said station.

20653—October 23—Authorizing C.P.R. to change present grade crossing on road allowance between Lots 34 and 35, Con. 1, Tp. Scarborough; and construct additional track (double track) by means of a grade crossing, across said road allowance, at mileage 91.2, on Con.'s main line, Toronto, Subdivision.

20654—October 23—Authorizing C.N.O.R. to construct across Third Street, town of North Bay, Ontario.

20655—October 22—Refusing application of village of Brechin for an Order directing C.P.R. to move its station from present location (approved by Order No. 15165, dated October 20th, 1912,) to a point nearer said village.

20656—October 22—Authorizing C.N.O.R. to construct, at its own expense, across Eglinton Avenue, between Lot 1, Con. 4, and Lot 5, Con. 3, Tp York, Co. York, Ontario.

20657—October 24—Authorizing C.N.R. to open for traffic that portion of its line from Macrorie to Tichfield, a distance of six (6) miles, and from the junction between Macrorie and Tichfield to Elrose, a distance of fifty (50) miles, in Prov. Sask.; trains operated over said line be limited to a speed not exceeding eighteen (18) miles an hour.

20658—October 24—Extending, until December 31st, 1914, time within which Quebec Oriental Ry. complete work of ballasting its railway from Metapedia to New Carlisle, with a complete lift of six (6) inches of ballast; and of renewing fences, gates, wooden culverts, and all decayed portions of trestles.

20659—October 23—Rescinding Order No. 19702, dated June 27th, 1913. 2. Approving Montreal and Southern Counties Ry. Co.'s Standard Passenger Tariff of Maximum Tolls, C.R.C. No. 4, on basis of 2½ cents a mile, to apply between Co.'s stations south of St. Lawrence River; said Tariff, with a copy of this Order, be published in at least two consecutive weekly issues of "The Canada Gazette."

20660—October 24—Dismissing application of Clifton Sand, Gravel and Construction Co., Limited, for an Order reducing, adjusting and fixing rates on sand, gravel and concrete material between Stamford, Ont., and surrounding points in Ontario, including Niagara Falls, Chippewa, Welland, Port Colborne, Thorold, Merritton, St. Catharines, Hamilton and Toronto and intermediate points.

20661—October 24—Authorizing town of Sarnia, Ont., to construct, at its own expense, highway across right of way and tracks of Pere Marquette Ry. at south limit of said town. 2. R.R. Co., at its own expense, raise its tracks so as to be level with highway, and keep cars 75 feet back from edge of crossing on each side. 3. R.R. Co. install improved automatic electric bell at said crossing, and thereafter maintain bell at its own expense. Town to reimburse R.R. Co. cost of installing said bell.

20662—October 24—Authorizing C.P.R. to construct road diversion in N.W. ¼ Sec. 8-11-9, W. 4 M., Alta.; and to construct tracks of its main line, Alta. Div., Lethbridge Subdivision, across said diversion.

20663—October 24—Amending Order No. 18110, dated November 23rd, 1912, by substituting name, "Robert W. King," for name, "King Constrnction Co.," wherever it occurs in said Order. 2. That words, "of the location of the said branch line, or spurs therefrom," following word "reason," where it appears in operative paragraph of said Order, be stricken out and following words substituted, "of the construction of the said branch line, or spurs therefrom, including damages, if any, occuring by reason of location of said branch line north of centre line of the said Sudbury Street." 3. That, with consent of all parties, Herbert E. Denton, Esquire, Junior Judge of the Co. York, be appointed Referee to ascertain and fix amount of compensation which Robert W. King, Wm. Bretzner, Mary Lyons, John McLean and John O'Neill are severally entitled to receive under terms of said Order No. 18110. 4. That costs of and incidental to said Reference, including those of said Referee shall be in discretion of said Referee. 5. That G.T.R. pay such, if any, snm or sums as said Referee may order to be paid to said claimants, or any of them.

20664—October 21—Directing that cost of installing new diamond, back-up derails, and derails necessitated by construction of double track at crossing by C.P.R. of G.T.R. in W. ½, Lot 14, Con. 2, Tp. Trafalgar, Co. Halton, Ont., at mileage 32.56 from Toronto, be paid by C.P.R. That cost of maintaining additional protection at said crossing be paid one-half by C.P.R., and one-half by G.T.R.

20665—October 27—Amending Order No. 180, dated July 6th, 1904, to provide further protection at crossing of Dundas Street, by G.T.R. and London Street Ry., city of London, Ont.

20666—October 25—Authorizing C.P.R. to open for traffic portion of double track from Pilot Butte, mileage 84.7 to Regina, mileage 92.0, Moose Jaw Subdivision, Prov. Sask.

20667—October 25—Authorizing C.P.R. to operate bridge No. 46.9 on Megantic Subdivision, Eastern Div.

20668—October 24—Recommending to the Governor in Council for sanction agreement entered into in duplicate, June 2nd, 1913, between C.P.R. and Kettle Valley Ry., providing for interchange of traffic between said two companies.

20669—October 24—Authorizing C.P.R. to construct siding for F. T. Proctor, Toronto, Ont., from point on S.W. limit of its main line, in Lot 10, 4th Con. West, Tp. Caledonia, Co. Peel, Ont., at mileage 24.5, Orangeville, Subdivision.

20670—October 23—Authorizing C.P.R. to construct, by means of grade crossing, its Ballast Pit spur across road al-

lowance between Indian Reserve and Tp. Thessalon, Dist. Algoma, Ont., mileage 3.08 of said spur, subject to certain conditions.

20671—October 24—Approving location C.L.O. and W. Ry. (C.P.R.) station at Bowmanville, in Subdivision, Lots 2 and 3, and Lot 13, Con. 1, Tp. Darlington, Co. Durham, Ont., lying west of Scugog Street, town of Bowmanville.

20672—October 25—Directing that New Ontario Farm and Townsites, Limited, and Lieutenant-Colonel Geo. A. Shaw, be declared parties interested and Respondents herein, together with Whitford Vanduson, the registered owner of land above mentioned. And authorizing C.N.O.R. to take, for purposes of efficient construction and operation of its railway, and in order to carry out works approved by Governor in Council on April 27th, 1910, portion Lot 13, Con. 1, Tp. Nepigon, Ont., paying compensation to parties entitled thereto in accordance with provisions of Railway Act.

20673—October 24—Approving revised location C.N.O.R. through Tp. York, and part city of Toronto, Ont., mileage 2.23 to 6.16 from Yonge Street, subject to certain conditions. And refusing Co.'s application for level crossing of C.P.R. main line.

20674—October 27—Authorizing C.N.R. to open for traffic its line from Alsask to Hanna, distance of 93 miles; and from Hanna to Munson, a distance of 40 miles.

20675—October 25—Authorizing C.N.R. to construct across Leitchfield Avenue, Athabasca, Alta., subject to terms of consent.

20676—October 23—Refusing application residents of La Conception, Que., for Order directing C.P.R. to employ an agent at La Conception. 2. C.P.R. provide telephone connection at La Conception Station with agent at Mont Tremlant, also with station at Labelle: That Conductors on Ry. Co.'s trains sell tickets to patrons boarding trains at said flag station or stations, on same basis and advantages as authorized at organized stations.

20677—October 24—Directing that C.N.O.R. forthwith construct livestock pass under its railway on farm of W. R. Kirk, Foresters Falls, Ont., on or beside his farm lane; pass to be 7 feet wide by 7 feet high, properly drained and paved. Co. also construct, at such points as Applicant may desire, grade crossing convenient and proper for farm purposes. Co. shall not block said grade crossing longer than five minutes at any one time when crossing is desired to be used.

20678—October 27—Rescinding Order No. 19468, June 4th, 1913; and Lake Erie and Northern Ry. is declared to have seniority as to trains over Brantford Street Ry., at point of crossing.

20679—October 23—Granting leave to Ottawa Electric Co. to erect poles and wires across C.P.R. on River Road, south of Hurdman's Bridge, Ottawa, Ont.

20680—October 23—Granting leave to Ottawa Electric Co. to erect poles and wires across C.P.R. on private road leading from River Road south, to Convent of Grey Nuns, near Hurdman's Bridge, Ottawa, Ont.

20681—October 27—Directing that, pending extension and operation of C.N.R. to Estevan, C.P.R. publish and file through freight tariff of class rates from Estevan, via Midale, to those points on C.N.R. to which through class rates, via Midale, are published and filed by C.P.R. from Weyburn, Sask., said through rates from Estevan not to exceed sums of published and filed local rates of C.P.R. to Midale and of C.N.R. from Midale to Weyburn destinations: Provided so long as Midale Transfer continues a non-agency, C.P.R. be permitted to consolidate less-than-carload shipments by holding them at Estevan until they approximate a carload of 20,000 lbs. in weight for transfer to C.N.R., without breaking bulk. Said tariff to be made effective not later than November 20th, 1913.

20682—October 27—Approving and authorizing clearances as shown on plan of door openings at factory of Canada Wire and Cable Company, Limited, Leaside, Ont.

20683—October 27—Approving plan showing method of temporarily reinforcing existing piers of New Brunswick Coal and Railway Co.'s Bridge No. 44.7 over Salmon River, near Chipman, New Brunswick.

TRADE ENQUIRIES.

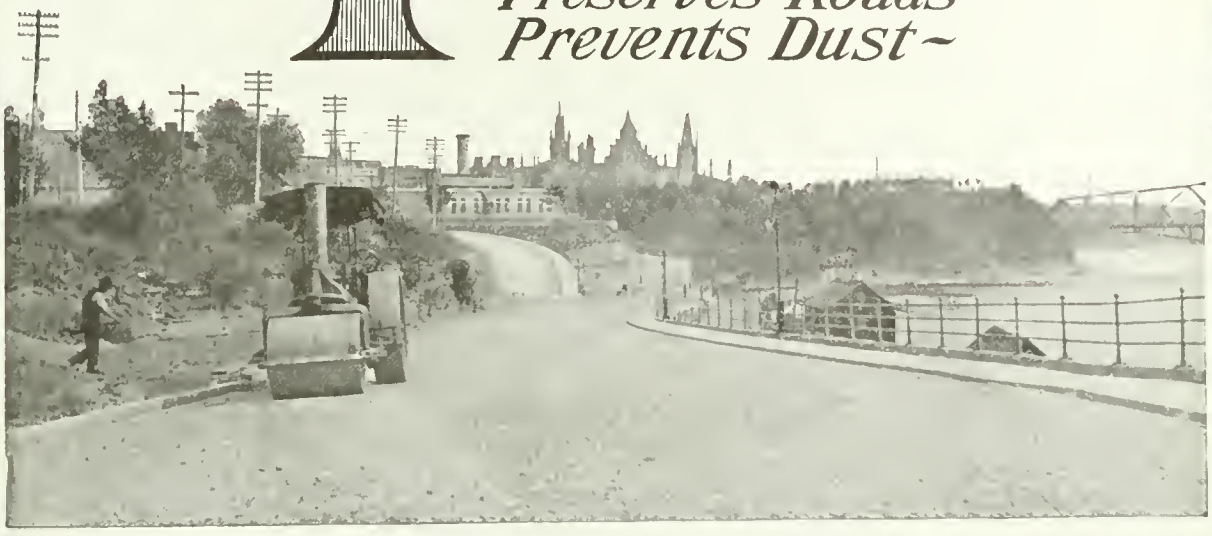
The following inquiries relating to Canadian trade have been received:—1105.—A Maritzburg firm of hardware merchants wishes samples and quotations of fencing wire. 1106.—A Natal firm desires quotations and samples of Canadian bolts and nuts. 1116.—A Natal firm of hardware merchants can handle a quantity of splitwood pulleys, small sizes, 6 to 18, and a few 24. 1163.—A South African firm wishes catalogues and quotations on Canadian-made shovels. 1168.—Quotations are requested by a South African firm of commission agents on Canadian lumber. 1175—A Johannesburg firm of lumber dealers requests quotations on best quality pine in the rough. Width, 12 inches and wider. 1176—A Johannesburg firm of lumber dealers desires quotations on best quality poplar lumber in the rough. Width, 12 inches and wider. 1177.—A Transvaal firm of lumber dealers desires quotations on No. 2 quality pine shelving. Width, 12 inches only. 1178.—A Johannesburg firm of lumber dealers request quotations on spruce shelving. Width, 12 inches only. 1179.—Quotations requested by a Johannesburg firm of lumber dealers on deals and timber of various sizes, all in the rough. 1181.—A Johannesburg firm of machinery dealers will take up a Canadian agency for above. 1182.—A Transvaal firm of machinery importers is willing to take up an agency for Canadian esbestos. 1204.—A Johannesburg firm of importers desires catalogues and prices of all kinds of Canadian-made mining tools. 1205.—Catalogues and prices are requested by a Transvaal importing house on all kinds of mining material. 1206.— A Johannesburg firm of mining material importers wishes catalogues and prices of Canadian manufactured mining machinery. 1289.—Wanted by a Bloemfontein firm, an agency for Canadian-made motor delivery waggons and vans. 1301.—An Orange Free State firm of importers requests prices and samples, if possible of Canadian-made leather belting. 1306.—A South African firm of hardware importers desires catalogues and prices of Canadian-made brickmaking machinery. 1308.—An Orange Free State firm of hardware merchants desires catalogues and prices on cranes and elevators of Canadian manufacture. 1309.—A South African firm of general merchants desires catalogues and prices on Canadian-made irrigation machinery. 1310.—An Orange Free State firm of hardware importers would like to communicate with Canadian manufacturers and exporters of milling machinery. Catalogues and prices requested. 1311.—A South African firm of general merchants requires catalogues and prices on sawing machinery of Canadian manufacture. 1312.—A South African firm of general importers wishes to correspond with Canadian manufacturers and exporters of mining machinery. Catalogues and prices required. 1313.—A Bloemfontein firm of hardware dealers would like to be placed in communication with Canadian manufacturers and exporters of windmills. Catalogues and prices requested. 1336.—A Capetown firm of commission agents wishes to be placed in communication with Canadian manufacturers and exporters of forges. 1374.—Samples and prices are requested on bolts and nuts of Canadian manufacture by a Natal firm. 1481.—A Transvaal firm of importers asks for catalogues and prices on mining tools of Canadian manufacture. 1482.—A South African firm of importers requests prices and catalogues on Canadian-made shovels.

The names of the firms making these inquiries may be obtained upon application to:—"The Inquiries Branch the Department of Trade and Commerce, Ottawa, or the Secretary of the Canadian Manufacturers' Association, Toronto; or the Secretary of the Board of Trade at London, Toronto, Brandon, Halifax, Montreal, St. John, Sherbrooke, Vancouver, Victoria, Winnipeg, Calgary, and Chambre de Commerce du District du Montreal."

The following was among the inquiries relating to Canadian trade received at the office of the High Commissioner for Canada, 17 Victoria Street, London, S.W. An engineer, in Yorkshire, who has, for many years' past specialized in the manufacture of brickmaking machinery, would like to correspond with manufacturers in Canada who might be disposed to enter into negotiations for the manufacture of machines from his patterns and drawings.

Tarvia

Preserves Roads
Prevents Dust~



Lady Grey Road, Government Road, Ottawa, Ont. Canada's Mint in foreground. Parliament Buildings in background. Tarvia Modern Pavement finished Aug. 1, 1913.

A New Principle in Road Building

IT has long been recognized by engineers that one of the greatest causes of the destruction of macadam roads by traffic has been the internal movement caused by the passage of heavy loads. The endless shifting and creeping of the lower courses of stone causes a grinding and pulverization which destroys the stone and breaks the bond.

To reduce this internal movement engineers have buried the larger stone under successive layers of finer stone. This fine stone forms dust more rapidly but the dust serves to protect the foundation of the road by acting as a cushion. Modern traffic makes the use of such dust cushions quite impracticable, for the automobiles not only stir up the dust but create entirely new conditions by scouring the surface of the road and breaking the bond with the backward thrust of their driving wheels.

The possibility of making roads automobile-proof by using Tarvia as a binder from top to bottom of the wearing-course during the construction of the road has now been satisfactorily demonstrated. The Tarvia fills the voids and forms a tough, durable matrix in which the stone cannot shift or grind. Consequently it has become possible to use large stone in a much greater proportion of the construction. The fine screenings and stone chips are used only on the surface as a finishing coat.

Traffic wearing away the surface strikes the layer of large stone in the tarvia matrix and makes little or no impression upon it. The large stone pulverizes but slowly and cannot be torn loose by automobile wheels. It does not change contour, sheds water instantly, is free from dust, costs but a trifle more to build than ordinary macadam, costs much less to maintain.

RAILWAYS—STEAM AND ELECTRIC.

Brantford, Ont.—It has been intimated that the management of the Brantford and Hamilton Radial Company is considering the advisability of double-tracking its line between Brantford and Hamilton. Also from what can be learned, the construction of another track between the points mentioned will be started in the spring.

Hamilton, Ont.—It has been learned that the Toronto, Hamilton and Buffalo Railway Company has in serious contemplation the addition to its services between Hamilton and Waterford, and particularly between Hamilton and Brantford, of steel gas-electric motor cars. It is understood that the company has ordered at least two of its engineers to prepare for the examinations on gas-electric engines, and that the motor cars will be of the latest type and design.

Medicine Hat, Alta.—An arrangement has been completed by which work on the railway spur to the west industrial site will be completed immediately. The financial responsibilities have been arranged for by Mr. A. M. Grace; and the C.P.R. has agreed to supervise the construction work and furnish the necessary motive power for the operation of the spur, which will be completed within the next two or three weeks.

Nelson, B.C.—By an overwhelming majority, the stockholders of the Nelson Street Railway Company voted to sell out to the city for 50 cents on the dollar, payable in 20-year 5 per cent. debentures. A by-law to authorize the issuance of bonds is to be submitted to the people at the same time as the by-law to purchase the gas plant for $50,000.

Ottawa, Ont.—It is stated that the tenders received by the Department of Railways for the Intercolonial terminals at Halifax do not meet with all the requirements, and it is understood that they will not be considered, but that new tenders will be called.

Owen Sound, Ont.—At a recent meeting of the Owen Sound board of trade, a resolution was adopted requesting the town council to appeal to the Ontario Government through the Hydro-Electric Commission to investigate the question of constructing a radial railroad from Owen Sound to Guelph. The government will be asked to furnish estimates of the cost.

Toronto, Ont.—Mr. T. J. Glover, promoter of the Forest Hill Railway, has announced that the company will spend $50,000 within a year on active construction work. Until the plans have been settled finally, the company will not declare the route of the road.

Vancouver, B.C.—It is reported that Sir Richard McBride, Premier of British Columbia, has concluded a deal with the Standard Oil Company to give them a charter at the coming session of the Provincial Legislature for a railroad to be built through to Alaska. The line is to run in connection with the Chicago, Milwaukee and St. Paul Railway, with headquarters at Seattle, linking the Pacific Great Eastern with Fort George.

Vancouver, B.C.—A reciprocity arrangement has been suggested by the Board of Railway Commissioners to deal with the respective applications from the Wellington Colliery Company to cross the tracks of the E. and N. Railway and vice versa.

Victoria, B.C.—The officials of the C.N.P. Railway Company are engaged in the preparation of plans for continuing the road towards the north of the Island. The announcement that no further contracts will be awarded until the Saanich work, now in progress and due to be finished by the end of January is concluded, does not mean that a line as far as Alberni, or even as far as Nootka Sound, shall be the extent of the company's operations. It has been announced that several survey parties have been employed in the country north of Alberni canal, and the impression is given that, as soon as the enterprise now in hand is completed, the company will undertake the penetration of the Island's extreme north. A definite survey has been prepared for a road connecting with the Canadian Northern Pacific at Alberni and running through to Nootka Sound, reaching the latter harbor by a route which, in its final stages, skirts the banks of the Muchalat Arm. En route, a branch has been run to Duncan Bay. This survey, except in some minor particulars, has been adopted, and, when the contractors are relieved of the work now in hand between this city and Alberni, it is probable that tenders will be called for this section. No actual line has been surveyed north of Nootka, but the report of a reconnaissance party, which has been in the field for some months, is said to have been of a very favorable character as to the practicability of continuing the road through

MANNESMANN TUBES

Six Hundred Authorities Are Using Mannesmann Tubes

in Great Britain in varying quantities up to 15 miles; in Canada, to 17 miles.

Seven hundred miles of weldless steel spigot and faucet tubes—quite apart from flanged tubes and lapwelded spigot and faucet tubes—are in use in the United Kingdom, as well as large quantities in Canada, Australia, South Africa, South America, India, China, New Zealand and Europe.

We are constantly adding new customers to our list, and, what is of even greater significance, more frequently still receiving repeat orders.

Solid drawn tubes are used in places where it is impossible to use cast-iron pipes or lapwelded tubes, as well as in places where the conditions are more normal.

In the past five years the sale of Mannesmann weldless steel spigot and faucet tubes (home trade alone) increased one thousand per cent., and during the last financial year reached the figure of about 5,000 tons, equal to 15,000 tons of cast-iron, in addition to a large export business.

BOOKLETS ON REQUEST

to Quatsino and the north end of the Island. It is said that it has been found that the summit in the Kla-Anch River country is not as formidable as has been thought, and that it will be possible to pick a first-class route into the most northerly regions of the Island.

Winnipeg, Man.—A spur line to serve the premises of the Midland railway industrial site has been approved by the Winnipeg works and property committee.

Winnipeg, Man.—The city light and power company has been granted permission by the public utilities commission to extend a line into the Grand Trunk Pacific shops, with the understanding that proper safety precautions be taken.

Winnipeg, Man.—Sir Thomas Shaughnessy, president of the C.P.R. Company, has assured Mr. Geo. H. Bradbury, M.P. for Selkirk constituency, that the extension of the Selkirk line to Icelandic River will be completed next summer without fail. This stretch of 20 miles is already graded and awaiting steel.

GARBAGE, SEWAGE AND WATER.

Fredericton, N.B.—As an endeavor towards securing a better quality of water than that reported by Mr. H. H. Hagerman, the analyst, the Board of Health has decided to address a letter to the city council, asking that steps be taken to remedy conditions at the filtration plant in connection with the Municipal Water Department, and also to forward to Alderman Everett, chairman of the water committee, a copy of the analyst's report. Immediate action by the council will be requested.

Medicine Hat, Alta.—Chief Provincial Engineer Owen is investigating the protest of Medicine Hat against sewerage from the town of Redcliff being drained into the Saskatchewan River above the water intake of Medicine Hat's waterworks system.

Medicine Hat, Alta.—Among other by-laws passed by the city council of Medicine Hat to be submitted to the people, in the event of the assent of the burgesses, upon the 29th of November, are one providing for borrowing $175,000 upon debentures to pay for extending and improving the waterworks system, and one for $60,000 to pay for the construction of surface and storm sewers throughout the city.

Montreal, Que.—The program of sewers to be undertaken next year will include the finishing of the trunk sewers from Notre Dame de Grace and from St. Denis wards to the Back River, and the construction of a new trunk sewer through the east end to Bout de l'Isle. The laying of miner sewers only where most needed will also form a small part of the program of sewer construction. The cost of the sewer from St. Denis ward alone will be in the neighborhood of $1,000,000.

Ottawa, Ont.—Tenders will be received up till November 6th for the construction of the West End intercepting sewer. Plans and specifications may be obtained from Arch. Currie, City Engineer, City Hall, Ottawa, Ont

+—Port Arthur, Ont.—The city of Port Arthur is installing a complete new waterworks system, comprising a duplicate pipe line of welded steel pipe of 24-inch diameter. This pipe line will be about five miles long, totalling 10 miles of pipe. The pipe is being delivered now, a considerable amount having already arrived by the boat-load manufactured in Coatbridge, Scotland, all subjected to test of 500 lbs, to the square inch. MESSRS. DRUMMOND McCALL of Montreal are the contractors for the delivery of this pipe and special parts. Six miles of pipe are already on hand, and it is hoped to have the balance by the close of navigation. A complete and up-to-date pumping station is being erected at the shore end of the intake, and the entire system will be completed and in operation by the summer of 1914.

Toronto, Ont.—The works department of Toronto will likely call for tenders within two weeks for one or two 20-million gallon pumps, 110 pounds pressure, for the main pumping station. Tenders will be asked on both high duty and centrifugal pumps. These two proposed pumps will bring the capacity of the main pumping station up to 106,000,000 gallons daily, or sufficient to handle the city's needs even after the installation of the filter plant.

▲—Toronto, Ont.—Tenders will be received up till November 15th for the construction of a sewer on Bathurst Street, in the Township of York. Plans and specifications may be obtained from Frank Barber, C.E., Township Engineer, 57 Adelaide Street East, Toronto, Ont.

Vancouver, B.C.—Early in November, the Burrard Peninsular sewerage commission will meet to consider calling for tenders for this winter's program of sewerage construction. This winter's work on the construction of the Greater Vancouver sewerage system will involve an expenditure of approximately $400,000; and in the spring $2,500,000 will be raised by the sale of bonds guaranteed by the Provincial Government to continue the work.

+—Victoria, B.C.—The city council has approved the letting of the contract for the construction of the concrete flow line to the GRAFF CONSTRUCTION COMPANY, providing the company satisfies the water commissioners on or before November 10 concerning certain phases of their tender for the Sooke Waterworks pipe-line.

Welland, Ont.—Hon. Frank Cochrane, in a letter to Mayor Goodwin, announces that the Government will not pay for all the loss Welland will suffer by reason of the demoralization of the waterworks system and sewage system when the canal is enlarged. He does not say just what proportion the Government will pay, but leaves the inference that the town will not be forced to assume the entire burden.

Winnipeg, Man.—The Northwest Ratepayers' Association are endeavoring to draw the attention of the Board of Control to the necessity of constructing a culvert across McPhillips Street at some convenient point to take away the surface water in the spring, and also a water main in Magnus Avenue, near the Stonewall branch of the C.P.R. to do away with the dead end in the vicinity.

Winnipeg, Man.—Mayor Deacon of Winnipeg has been requested to further the interests of Canadian contractors in the awarding of contracts for the Shoal Lake water scheme.

LIGHT, HEAT AND POWER.

Ayr, Ont.—A by-law is to be submitted to the municipality of Ayr on December 1st, concerning the making of a contract with the Hydro-Electric Power Commission for the supply of power to Ayr at an approximate cost of $38 per horsepower.

Halifax, N.S.—The result of the meeting of the Halifax Medical Council in connection with the typhoid epidemic raging in the city, was to adopt the following resolution and send it to the city Board of Health:—"Resolved that this society represent to the city Board of Health, its belief that the entire watershed of the lakes from which the city water supply is obtained, should become the property of the city, and that no person should be permitted to reside or trespass upon the watershed."

Kildonan, Man.—The municipal council has instructed Engineer Parr to negotiate with the solicitors the matter of by-laws for paving Main Street and East Kildonan road on the east and west sides of the river, the width to be 20 feet, and to be constructed adjacent to the proposed car line in the centre of the street. The engineer is also to furnish at once complete plans and estimates.

London, Ont.—The Ontario Hydro-Electric Power Commission are considering the estimates which are now in their hands for the proposed contract for hydro power between the London street railway and the local water commission. The estimates include the street railway company's revision.

London, Ont.—The London Street Railway and Water Commission has completed to all practical purposes the agreement by which the street railway will use the hydro-electric power. The company is to take a minimum of 1,000 horsepower, direct current; and in order to convert the power to alternating current a rotary generator will be installed at a cost of $20,000. It is expected that the agreement will be finally signed within a couple of days, and this agreement will run for 12 years—e.g., to the end of the present franchise of the street railway.

Medicine Hat, Alta.—Two by-laws will be voted upon at Medicine Hat on November 20th in connection with the city's light and power department, the first to provide for borrowing $150,000 upon debentures to pay for increasing and extending the electric light and power plant and for extending and improving the electric light and power systems; the second, to provide for borrowing $50,000 upon deben-

tures for extending the city's gas system, and for drilling, boring, and constructing gas wells for any purpose authorized by the Medicine Hat charter.

New Glasgow, N.S.—The Pictou County Electric Company are enlarging the capacity of their power plant at Stellarton. An outfit that will double the present equipment, consisting of boilers, generators, engines, etc., has been purchased and will be completely installed within a month's time.

Ottawa, Ont.—The control of the Great Falls on the Winnipeg River has passed into the hands of the Winnipeg Electric Railway. The lease runs for a period of 21 years, renewable for three further similar periods, or altogether for 84 years. The Government will control the rates to be charged to the consumer, and the rental will be considered at every renewal. The Government further reserve the right at the end of each period or at the conclusion of the 84 years to buy back the development. According to the new agreement the development must be carried out as a component part of a comprehensive scheme of power development comprising all the falls on the river between Lac du Bonnet and Lake Winnipeg. This scheme contemplates the concentration at the various falls of the river at three points where 75,000 horsepower can be developed. These three points are Pine Falls, Great Falls and McArthur Falls. Surveys and investigations leading up to the extensive power scheme have been under way for the past three years and have just been completed. Work has been carried on by expert engineers under the advice of consulting engineers prominent in hydro-electric practice. A full report of this investigation is under preparation and will be published at an early date. J. T. Johnston, hydraulic engineer of the waterpower branch, is now on his way to Winnipeg to confer with the engineer retained by Sir William Whyte and to satisfy the department that the Great Falls development will not be inimical to the more comprehensive scheme of development proposed.

Ottawa, Ont.—City Bacteriologist Race reported rather favorably on the present condition of the Ottawa River water at a Board of Health meeting recently. Only in one ward, Capital Ward, were the marked signs of contamination most prevalent. This he attributed to the number of dead ends of pipes in that section and advocated more frequent flushing. He regarded, however, the Gatineau lakes as the solution of Ottawa's water problem.

Regina, Sask.—The city commissioners have opened tenders for a 3,000 k.w. turbo-alternator, which it is estimated will be required about a year from now. They have also referred to the decision of the Fire, Light and Power Committee a recommendation for a contract for the supply of a travelling crane for the new power house based upon the tenders which have been received.

St. Catharines, Ont.—The Hydro-Electric by-laws, which were voted upon at St. Catharines on October 30th, met with very slight opposition. The city will now be enabled to sign the contract with the Hydro-Electric Commission, and to issue $116,000 debentures for the establishment of a distributing system and stepping-down plant to use the Hydro power, which is to be sold to the city at $14 per horsepower.

+—Toronto, Ont.—An agreement of contract has been signed between the TORONTO HYDRO-ELECTRIC COMMISSION and the T. Eaton Co., Limited, for the supply of 2,000 kilowatts, or about 2,500 horsepower, of electrical energy from the commission. This additional amount of energy is required by the T. Eaton Company as a supplement to the supply generated by its own plant, and will cost the company about $50,000 per year. This contract is the largest yet obtained by the commission with the possible exception of the agreement for the supply for the dredging operations in Toronto Bay; and the commission will have to increase its supply from the provincial commission to meet the requirements of the new contract.

Welland, Ont.—The report of the provincial analyst received by Dr. Howell, M.O.H., on samples of water recently sent to be tested, has shown the spring water at the east end of the canal to be badly contaminated, and the well has been closed to the public.

Winnipeg, Man.—Tenders will be received up till December 1st, 1913, for the supply of d.c. and a.c. meters as may be required by the city Light and Power Department during one year from the date of contract. Plans and specifications may be obtained from the city Light and Power Department, 54 King Street, Winnipeg, Man. Signed, M. Peterson, Secretary, Board of Control, Winnipeg.

Winnipeg, Man.—Public Utilities Commissioner Robson announced recently that, in accordance with the policy outlined at the last session of the Manitoba Legislature, he is now prepared to go to outside points in the province to hear representations in regard to water power, this with a view to the establishment of a hydro-electric commission for Manitoba.

BRIDGES, ROADS AND PAVEMENTS.

Assiniboia, Man.—Tenders will be received up till November 25th for the construction of an asphalt pavement on the north side of Portage Road, for approximately 7¼ miles. Plans and specifications may be obtained from Frank Ness, Clerk, Rural Municipality of Assiniboia, Man.

Edmonton, Alta.—A petition signed by all the wholesalers in the district on 103rd and 10th Streets has been presented to the city commissioners, asking for the opening of a subway under the Canadian Northern yards on 104th Street, and has been referred to the city council.

Guelph, Ont.—Though the time limit set for the contractors who are building the Heffernan Street bridge has expired, the bridge is far from being completed.

Kamloops, B.C.—The Canadian Northern Pacific Railway Company are commencing the construction of the second bridge across the North Thompson River above Kamloops. The structure is to be a seven 80-foot deck girder span bridge.

Kildonan, Man.—In a recent meeting of council, it was suggested that a bridge should be built over the Red River to give better communication between the communities on the two sides of the river. A committee was appointed, also, to wait upon the provincial minister of public works to see what grants the department would allow for improvements to the roads of the municipality.

Le Pas, Man.—It is announced that work on the steel bridge across the Narrows at Cormorant Lake, on the Hudson Bay Railway is to be commenced soon, and that the two abutments for the cantilever bridge across the Nelson River will be built this winter. The necessary cement is to be hauled from Whiskey Jack Portage on Cross Lake, at the head of Lake Winnipeg.

Medicine Hat, Alta.—The city council has passed a by-law to be submitted to the people on November 29th for the borrowing of $50,000 upon debentures for grading and gravelling of streets and for purchasing road construction plant and machinery.

Ottawa, Ont.—Ex-Mayor Charles Hopewell appeared on behalf of the Ottawa Valley Motor Car Association before the Public Roads and Highways Commission, which met in Ottawa recently, and advanced reasons for the construction of an adequate highway between Ottawa and Prescott.

Toronto, Ont.—Mr. Frank Barber, engineer for York Township, has completed, in accordance with the order of the council, some weeks ago, plans for a high-level bridge over the West Don River, alongside the C.P.R. viaduct No. 3, and approximately at the corner of Leslie Street and Eglinton Avenue. The construction of this bridge will mean that Eglinton Avenue will be made a through road on high level.

▲—Toronto, Ont.—Tenders will be received up till November 8th for the construction of Rocmac Pavement on Spadina Road, in the Township of York. Plans and specifications may be obtained from Frank Barber, C.E., 57 Adelaide Street East, Toronto, Ont.

▲—Toronto, Ont.—Tenders will be received up till November 14th for the construction of pavement on King and Guelph Streets, Preston, Ont. Plans and specifications may be obtained from Frank Barber, C.E., 57 Adelaide Street East, Toronto, Ont.

Vancouver, B.C.—Mr. O. S. Bowen, Seattle, the assistant chief engineer of the Great Northern Railway, stated recently in Vancouver that the railway corporation propose to commence in the near future work on the permanent bridge over the Grandview cut at Broadway. The structure will be of 4-plate girder spans, and of the best type of construction.

Vancouver, B.C.—The Ward Four Ratepayers' Association has endorsed the extension of Venables Street along the British Columbia Electric Railway Company's right-of-way.

700 Bullitt Building Philadelphia, Pa.

Estimates of that scheme and of the alternate plan of a route by Prior Street were submitted to the association, but a resolution was passed approving the former; and coupled with it was a condition requiring the British Columbia Electric Railway Company to lay double tracks on Prior Street from Campbell Avenue to Main Street, when requested to do so by the city council.

Vancouver, B.C.—The civic board of works and the C.P.R. officials have come to an agreement concerning the taking over, by the city, of Hamilton and Mainland Streets, which lie in the C.P.R. warehouse reserve. The railway company is to pay for half the paving of the streets on which their tracks run, including the 6-foot sidewalk, and will, moreover, arrange with the property owners as to the building of the concrete platform at the side of the portion of the street to be taken over by the city.

Vancouver, B.C.—The Board of Railway Commissioners has decided with respect to the application made by the V.V. and E. Railway for the purpose of diverting Gunn Road and Brunette Road and a protest from the municipality of Coquitlam on the same question, that a previous order issued by the Board covered the situation. Chairman Drayton directed that a conference be held between the railway engineers and the city of New Westminster to settle other debated points.

Vancouver, B.C.—The Great Northern Railway has been given a peremptory notice by the Railway Board of Commissioners to reach an agreement with the city of Vancouver within 30 days respecting plans for the proposed overhead bridges at Hastings, Pender, Keefer and Harris streets. And seven days, after the expiration of the 30-day limit set for the railway company, were allotted the company and the city to forward the result of their conferences on the viaduct question to the Board of Commissioners for approval.

+—Victoria, B.C.—The contract for the erection of Taghun Bridge, near Nelson, B.C., involving an expenditure of about $75,000, has been awarded by the Department of Public Works. The CANADIAN NORTHWESTERN STEEL COMPANY will supply the steelwork at approximately $4.45 per 100 pounds of metal. HUDSON KING AND PHELAN BROTHERS were awarded the contract for concrete substructure and the work of erection, at a cost of about $55,000. The work is to be commenced at once, so as to have the bridge completed for the early summer traffic next year.

Victoria, B.C.—The Inner Harbor Association has added its objection to that of the city council made recently, to the erection of a trestle viaduct by the C.N.P. Railway Company over the Victoria Arm. The association object for several reasons, its first one endorsing that of the city council, e.g., that a pile viaduct and bank would be the ugliest form by which the beautiful stretch of water, the Victoria Arm, could be crossed.

Victoria, B.C.—A proposal is being made before the Federal Government for a resolution to set aside a large sum for the construction and maintenance of highways, the money to be divided among the provinces upon a subsidy basis.

INDUSTRIAL WORKS.

Fredericton, N.B.—The survey being conducted by the Dominion Government Department of Public Works to make the final estimates of the dredging work done in the St. John River last summer was completed last week.

Le Pas, Man.—As much work as weather will permit is to be done on the Hudson Bay Railway terminals east of Le Pas this fall, and next spring work will be commenced on the roundhouse and machine shops, plans for which have been prepared. The site of the $75,000 station has not yet been determined; but this building is to be completed by January 1st, 1915.

Ottawa, Ont.—Tenders will be received up till December 1, 1913, for the construction of a wharf at Heustis Landing, Queen's Co. N.B. Plans and specifications may be obtained from the Department of Public Works, Ottawa, Ont. R. C. Desrochers, Secretary.

Montreal, Que.—The Harbor Commissioners have completed the purchase of a block of east end land for $163,312, which has been secured for harbor extension down the river.

New Westminster, B.C.—At the recent meeting of the Board of Railway Commissioners held in Vancouver, it was agreed that an arrangement should be made later to decide on an application made by the city of New Westminster for an order to apportion the cost of a concrete retaining wall to replace wooden crib work in front of the Penitentiary Grounds.

▲—Ottawa, Ont.—Tenders will be received up till November 18th for the construction of Section No. 5, Welland Ship Canal. Plans and specifications may be obtained from the office of the Chief Engineer, Department of Railways and Canals, Ottawa. Signed, L. K. Jones, Esq., Assistant Deputy-Minister and Secretary, Department of Railways and Canals.

▲—Ottawa, Ont.—Tenders will be received up till November 20th, 1913, for the construction of about 6,500 lineal feet of quay wall, foundations for buildings, sewers, dredging and filling of reclaimed areas. Plans and specifications may be obtained from L. K. Jones, Esq., Assistant Deputy Minister and Secretary, Department of Railways and Canals, Ottawa, Ont.

▲—Ottawa, Ont.—Tenders will be received up till December 2nd, 1913, for the construction of a wharf and warehouse at Richard's Landing, St. Joseph Island, Algoma District, Ont. Plans and specifications may be obtained from the Department of Public Works, Ottawa, Ont. R. C. Desrochers, Secretary.

Ottawa, Ont.—The award of contract for Section 3, Welland Ship Canal, to Baldry, Yerburgh, and Hutchinson, at $5,377,185, has been formally confirmed by the Cabinet of the Dominion Government; and tenders for the 5th division are called. This divison is 3 miles in length, extending from a point in Port Robinson to a point in about the centre of Allenburg. Comparatively little rock-cutting will have to be done on this section, and the cost is not expected to exceed three million dollars.

Ottawa, Ont.—Tenders will be received up till December 9th for the construction of wharves at Victoria Harbor, B.C. Plans and specifications may be obtained from the Department of Public Works, Ottawa, Ont. R. C. Desrochers, Secretary.

Ottawa, Ont.—Tenders will be received up till November 24th for the construction of East Breakwater Pier at Seal Cove, Grand Manan Island, Charlotte Co., N.B. Plans and specifications may be obtained from the Department of Public Works, Ottawa, Ont. R. C. Desrochers, Secretary.

Ottawa, Ont.—Tenders will be received up till November 12th, 1913, for improving the lower entrance to Lock No. 20. Plans and specifications may be obtained from the Department of Railways and Canals, Ottawa, Ont. L. K. Jones, Esq., Assistant Deputy Minister and Secretary.

Ottawa, Ont.—Tenders will be received up till December 1st, 1913, for the construction of an extension to the wharf at Callendar, Ont. Plans and specifications may be obtained from the Department of Public Works, Ottawa. R. C. Desrochers, Secretary.

Saskatoon, Sask.—The commissioners have recommended to the city council the construction this year of a concrete tunnel at the pumping station between the intake well and the low water pump well; and that James Priel, contractor for the tunnel now in course of construction at the pumping station, be allowed to undertake this additional work for $6,013 plus extras incurred on account of the lateness of the season.

St. John, N.B.—A committee from the board of trade is to be appointed to sit with the Common Council in a joint meeting with the Minister of Public Works. The committee will ask for the immediate letting of contracts for the construction of two new concrete docks on the West side, and that these new berths be rushed to completion to be ready in plenty of time for next season. The committee will urge also the construction of a new grain elevator with the new conveyers and general equipment necessary to provide grain facilities for the new berths desired. Finally, the completion of the entire contract in connection with the development at Courtenay Bay will be urged within a time limit of two and a half years instead of three and a half years as the contract now stands.

Toronto, Ont.—It is understood that the Canadian Stewart Company, Limited, C.P.R. Building, Toronto, desire to sub-let to other contractors considerable sea wall, ship channel and crib work in connection with its Toronto Harbor contracts.

(Continued on page 88a.)

Why Lose Time "Shopping"

When You Can Buy Anything You Want

"Under One Roof"?

It is just as great a convenience to engineers, contractors and builders to be able to get their supplies from one house as it is to the general public to shop in a large modern department store. The rise of the department store has been the result of economic conditions.

Likewise our business has evolved into a departmental house in the mechanical world in obedience to the same economic law.

This bringing together of a vast number of lines and classifying them according to departments is the kind of combination in industry that makes for efficiency, economy and better service.

Canada's Departmental House for Mechanical Goods

Can supply you with material all the way from nuts to machine tools and oil engines.

Our business is divided into about a dozen diff rent departments, as follows:—Scale Department, Engine Department, Valve and Steam Goods Department, Pump Department, Electrical Department, Transmission Department, Railway and Contractors' Supply Department, Small Tool and Supply Department, Safe and Typewriter Department, and Motor Truck Department.

From time to time we advertise products from the different departments that we think readers of *The Canadian Engineer* are interested in, but you should not by any means infer that those are the only goods we handle.

In this new series of advertisements we wish to drive home the fact that we are literally a "Departmental House for Mechanical Goods."

All you need to do is to make known to us your requirements. Write, telephone, or call.

The Canadian Fairbanks-Morse Co.

LIMITED

TENDERS CALLED FOR

Sealed tenders addressed to the undersigned and endorsed "Tender for Construction of Wharfs at Victoria Harbor, B.C.," will be received at this office until 4 p.m., on Tuesday, December 9, 1913, for the construction of Wharfs at Victoria Harbor, B.C.

Plans, specification and form of contract can be seen and forms of tender obtained at this Department and at the District Engineers' offices at New Westminster, B.C.; Victoria, B.C.; Confederation Life Building, Toronto, Ont.; Post Office Building, Montreal, P.Q.; and on application to the Postmaster at Vancouver, B.C.

Persons tendering are notified that tenders will not be considered unless made on the printed forms supplied, and signed with their actual signatures, stating their occupations and places of residence. In the case of firms, the actual signature, the nature of the occupation, and place of residence of each member of the firm must be given.

Each tender must be accompanied by an accepted cheque on a chartered bank, payable to the order of the Honorable the Minister of Public Works, equal to five per cent. (5 p.c.) of the amount of the tender, which will be forfeited if the person tendering decline to enter into a contract when called upon to do so, or fail to complete the work contracted for. If the tender be not accepted the cheque will be returned.

The Department does not bind itself to accept the lowest or any tender.

By order,
R. C. DESROCHERS,
Secretary.

Department of Public Works,
Ottawa, October 27, 1913.

Newspapers will not be paid for this advertisement if they insert it without authority from the Department.—45197.

Sealed tenders addressed to the undersigned, and endorsed "Tender for Harbor and River Improvements in the Mission River, Fort William, Ont.," will be received at this office until 4 p.m., on Friday, November 21, 1913, for the construction of the Harbor and River Improvements.

Plans, specifications and form of contract can be seen and forms of tender obtained at this Department and at the offices of W. P. Merrick, Esq., District Engineer, Fort William, Ont.; J. G. Sing, Esq., District Engineer, Confederation Life Building, Toronto, Ont.; J. L. Michaud, Esq., District Engineer, Post Office, Montreal, P.Q.

Persons tendering are notified that tenders will not be considered unless made on the printed forms supplied, and signed with their actual signatures, stating their occupations and places of residence. In the case of firms, the actual signature, the nature of the occupation, and place of residence of each member of the firm must be given.

Each tender must be accompanied by an accepted cheque on a chartered bank payable to the order of the Honorable the Minister of Public Works, equal to ten per cent (10 p.c.) of the amount of the tender, which will be forfeited if the person tendering decline to enter into a contract when called upon to do so, or fail to complete the work contracted for. If the tender be not accepted the cheque will be returned.

The Department does not bind itself to accept the lowest or any tender.

By order,
R. C. DESROCHERS,
Secretary.

Department of Public Works,
Ottawa, October 22, 1913.

Newspapers will not be paid for this advertisement if they insert it without authority from the Department.—46879.

DEPARTMENT OF RAILWAYS AND CANALS, CANADA.

ONTARIO—ST. LAWRENCE CANALS, CORNWALL CANAL.

Sealed tenders addressed to the undersigned and endorsed "Tender for Improving Lower Entrance to Lock No. 20," will be received at this office till 16 o'clock on Wednesday, November 12th, 1913.

Plans, specification and form of contract to be entered into can be seen on or after this date at the office of the Chief Engineer of the Department of Railways and Canals, Ottawa, and at the office of the Superintending Engineer of the Ontario-St. Lawrence, Cornwall, at which places Forms for Tender may be obtained.

An accepted bank cheque on a chartered bank of Canada for the sum of $2,000 made payable to the order of the Minister of Railways and Canals, must accompany each tender, which sum will be forfeited if the party tendering declines entering into contract for the work, at the rates stated in the offer submitted.

The cheque thus sent in will be returned to the respective contractors whose tenders are not accepted.

The cheque of the successful tenderer will be held as security, or part security, for the due fulfilment of the contract to be entered into.

The lowest or any tender not necessarily accepted.

By Order,
L. K. JONES,
Assistant Deputy Minister and Secretary.

Department of Railways and Canals,
Ottawa, 31st October, 1913.

Newspapers inserting this advertisement without authority from the Department will not be paid for it.—50153.

DEPARTMENT OF RAILWAYS AND CANALS, CANADA.

CANADIAN GOVERNMENT RAILWAYS.

HALIFAX OCEAN TERMINALS RAILWAY, HALIFAX, N.S.

CALL FOR NEW TENDERS.

Sealed tenders addressed to the undersigned and endorsed "Tender for Docks, First Unit, Contract No. 3," will be received at this office until 12 o'clock noon, Thursday, November 20, 1913, for the construction of about 6,500 lineal feet of quay wall, foundations for buildings, sewers, dredging of harbor to a depth of 45 feet at low water and filling reclaimed areas.

Plans and specifications and form of tender may be seen and full information obtained at the office of the General Manager, Moncton, N.B., at the office of the Chief Engineer of the Department of Railways and Canals, Ottawa, and at the office of the Superintending Engineer, Halifax, N.S.

The right is reserved to reject any or all tenders.

By Order.
L. K. JONES,
Assistant Deputy Minister and Secretary.

Department of Railways and Canals,
Ottawa, 30th October, 1913.

Newspapers inserting this advertisement without authority from the Department will not be paid for it.—50200.

Insurance Engineering

We maintain a skilled force of engineers and inspectors to advise in regard to the insurance of industrial undertakings.

We offer our services as consultants to engineers and architects who have charge of industrial construction. We have a thorough knowledge of fire protection and the many matters which govern insurance rating.

Manufacturers are invited to permit us to make an inspection and to let us make suggestions regarding fire protection which will add security and also likely more than pay for themselves through reduced insurance rates.

Insurance may be placed through our firm in the same manner as it would be through other insurance brokerage firms. The service rendered—in most cases without cost to our clients—by our staff of inspectors and engineers makes it profitable for owners who are placing insurance on industrial undertakings to place the insurance through our firm.

TENDERS CALLED FOR

DEPARTMENT OF RAILWAYS AND CANALS, CANADA.

WELLAND SHIP CANAL.

SECTION No. 5.

NOTICE TO CONTRACTORS.

Sealed Tenders, addressed to the undersigned and marked "Tender for Section No. 5, Welland Ship Canal," will be received at this office until 12 o'clock noon on **Tuesday, November 18th, 1913.**

Plans, specifications and form of contract to be entered into can be seen on or after this date at the office of the Chief Engineer of the Department of Railways and Canals, Ottawa, and at the office of the Engineer in Charge, St. Catharines, Ontario.

Copies of plans and specifications may be obtained from the Department on the payment of the sum of fifty dollars. To bona fide tenderers this amount will be refunded upon the return of the above in good condition.

Parties tendering will be required to accept the fair wages schedule prepared or to be prepared by the Department of Labor, which schedule will form part of the contract.

Contractors are requested to bear in mind that tenders will not be considered unless made strictly in accordance with the printed forms, and in the case of firms, unless there are attached the actual signature, the nature of the occupation, and place of residence of each member of the firm.

An accepted bank cheque on a chartered bank of Canada for the sum of $100,000.00 made payable to the order of the Minister of Railways and Canals, must accompany each tender, which sum will be forfeited if the party tendering declines entering into contract for the work, at the rates stated in the offer submitted.

The cheque thus sent in will be returned to the respective contractors whose tenders are not accepted.

The cheque of the successful tenderer will be held as security, or part security, for the due fulfilment of the contract to be entered into.

The lowest or any tender not necessarily accepted.

By order,

L. K. JONES,
Assistant Deputy Minister and Secretary.

Department of Railways and Canals,
Ottawa, 29th October, 1913.

Newspapers inserting this advertisement without authority from the Department will not be paid for it.—50010.

PROPOSED GOVERNMENT BUILDINGS, OTTAWA, ONT.

EXTENSION OF TIME.

Notice is hereby given that the time for the reception of designs in the first competition for the erection of Departmental and Courts Buildings, is extended for three months to Thursday, April 2nd, 1914.

By order,

R. C. DESROCHERS,
Secretary.

Department of Public Works,
—49657. Ottawa, October 23, 1913.

Sealed tenders addressed to the undersigned and endorsed "Tender for Wharf and Warehouse at Richard's Landing, Ont.," will be received at this office until 4 p.m., on Tuesday, December 2, 1913, for the construction of a Wharf and Warehouse at Richard's Landing, St. Joseph Island, Algoma District, Ontario.

Plans, specification and form of contract can be seen and forms of tender obtained at this Department and at the District Engineer's offices, Sault Ste. Marie, Ont.; Confederation Life Building, Toronto, Ont., and on application to the Postmaster at Richard's Landing, Ont.

Persons tendering are notified that tenders will not be considered unless made on the printed forms supplied, and signed with their actual signatures, stating their occupations and places of residence. In the case of firms, the actual signature, the nature of the occupation and place of residence of each member of the firm must be given.

Each tender must be accompanied by an accepted cheque on a chartered bank, payable to the order of the Honorable the Minister of Public Works, equal to ten per cent. (10 p. c.) of the amount of the tender, which will be forfeited if the person tendering decline to enter into a contract when called upon to do so or fail to complete the work contracted for. If the tender be not accepted the cheque will be returned.

The Department does not bind itself to accept the lowest or any tender.

By Order,

R. C. DESROCHERS,
Secretary.

Department of Public Works,
Ottawa, October 31, 1913.

Newspapers will not be paid for this advertisement if they insert it without authority from the Department.—48268.

SPECIAL NOTICE TO CONTRACTORS.

RE GREATER WINNIPEG WATER SUPPLY.

(Estimated Cost $13,500,000.)

Notice is hereby given to Contractors that tenders will be invited early in the year 1914 for the construction of works necessary for the delivery of water from Shoal Lake to the Greater Winnipeg Water District. The following is a brief description of the proposed works:—

1. A dyke and channel for the diversion of the Falcon River into Snowshoe Bay.
2. 85 miles concrete aqueduct.
3. 10 miles pipe line (probably 1916 work).
4. 900 lineal feet tunnel under Red River.
5. 85 miles of construction railway.
6. Telephone line.
7. Clearing and ditching.

The fall season of the year affords the best opportunity for inspection of proposed route of the aqueduct, and it is recommended that contractors having a view to tendering on the work should send their inspectors over the line at as early a date as possible.

Particulars as to estimated cost of the work and map of approximate location and profile of aqueduct may be obtained from the undersigned.

M. PETERSON,
Acting Secretary of the
Administration Board,
Greater Winnipeg Water
District.

City Hall,
Winnipeg, Canada,
October 6th, 1913.

Note.—Copy of report of the Consulting Engineers, plan and profile of work and typical details of design may be seen at the office of *The Canadian Engineer*, 62 Church Street, Toronto.

(For further Tenders see pages 84 and 88.)

MEXICAN EAGLE ASPHALT

TRADE MARK

Delivered to meet the specifications of the American Society for Municipal Improvements, the Association for Standardizing Paving Specifications or any other standard specifications

Purchase MEXICAN EAGLE ASPHALT because:

1—It is more cementitious than other asphalts.

2—Water will not readily injure it.

3—Exposure to sun and air will not cause its deterioration.

4—It has great cohesive strength.

5—It is more ductile and flexible than other asphalts.

6—Shocks will not crack it. It is very malleable.

7—We will supply asphalt having the proper penetration for your needs.

8—It is best adapted to Canada's climate—will not mark in hot weather—nor are snow or ice likely to crack it.

9—It has over 99 per cent. bitumen. Purest on the market—therefore free from deleterious matter.

10—It is so constituted that it will not be injured by the heat necessarily applied to melt it for paving operations.

Samples, prices, analyses, etc., on request.

TRANSPORTATION BUILDING — MONTREAL

TENDERS CALLED FOR

CANADIAN GOVERNMENT RAILWAYS.

TENDER.

Sealed tenders addressed to the undersigned and marked on the outside, "Tender, Diversion of Line, North Sydney to Leitches Creek," will be received up to and including

Monday, November 10th, 1913,

for the construction of a line of railway from North Sydney to Leitches Creek, N.S.

Plans and specification may be seen at the office of the undersigned at Ottawa, Ont., at the Station Master's Office, North Sydney, N.S., at the office of the Resident Engineer, at New Glasgow, N.S., and at the office of the Chief Engineer, Moncton, N.B., where forms of tender may be obtained.

All the conditions of the specification must be complied with.

L. K. JONES,

Assistant Deputy Minister and Secretary, Department of Railways and Canals.

Ottawa, Ont., October 24th, 1913.

RURAL MUNICIPALITY OF ASSINIBOIA.

NOTICE.

Sealed tenders, marked "Tenders for pavement," will be received by the undersigned up to 4 o'clock p.m., on Tuesday, the 25th day of November, 1913, for the construction of an asphalt pavement, on the north side of Portage Road, from the westerly limit of Lot 113, St. Charles, to the westerly limit of the Municipality—an approximate length of 7¼ miles—the first 1¼ miles to be 24 feet in width, and the balance 16 feet in width.

Plans and specifications may be seen at the office of the Municipal Engineer, Municipal Hall, St. Charles.

A marked cheque for 5 per cent. of the amount of tender must accompany each tender, which will be forfeited, should the successful tenderer refuse or neglect to enter into a contract, or to proceed with the work, as required in the specifications.

Tenders will also be accepted for pavements other than asphalt, in which case persons tendering must furnish plans, specifications and details of same.

The lowest or any tender not necessarily accepted.

By order of the Council.

FRANK NESS, Clerk,
Rural Municipality of Assiniboia.

Kirkfield Park P.O., Man., October 24th, 1913.

TENDERS FOR ROCMAC PAVEMENT.

Sealed Tenders plainly marked as to contents will be received at the office of the undersigned up to **Six o'clock of Saturday, November 8th, 1913,** for the construction of Rocmac Pavement on Spadina Road in the Township of York.

Plans, specifications and all information may be obtained at the office of Frank Barber, C.E., 57 Adelaide Street East, Toronto.

The lowest or any tender not necessarily accepted.

FRANK BARBER,
Township Engineer.

Toronto, November 4th, 1913.

TENDERS FOR IRON POSTS.

Sealed tenders addressed to the undersigned and endorsed "Tenders for Iron Posts," will be received at the Department of the Interior, up to noon of the 1st day of December, 1913, for the furnishing of fifteen thousand small and five hundred large iron posts for use on the survey of Dominion Lands, to be delivered at Edmonton on or before the 31st day of January, 1914.

Forms of tender and detailed information may be obtained from the Surveyor-General of Dominion Lands, Ottawa.

The tender must be accompanied by an accepted cheque on a chartered Canadian bank for the sum of two hundred dollars, payable to the order of the Deputy Minister of the Interior. This cheque will be forfeited if the party whose tender is accepted declines to enter into a contract to deliver the posts or fails to carry out the contract. If the tender is not accepted the cheque will be returned.

The Department does not bind itself to accept the lowest or any tender.

Newspapers copying this advertisement without authority from the Department will not be paid.

L. PEREIRA,
Secretary.

Department of the Interior,
Ottawa, October 31st, 1913.

TENDERS FOR CONSTRUCTION OF SEWER.

Sealed Tenders plainly marked as to contents will be received at the office of the undersigned up to **Noon of Saturday, November 15th, 1913,** for the construction of a Sewer on Bathurst Street in the Township of York.

Plans, specifications and all information may be obtained at the office of Frank Barber, C.E., 57 Adelaide Street East, Toronto.

The lowest or any tender not necessarily accepted.

FRANK BARBER,
Township Engineer.

Toronto, November 4th, 1913.

TENDERS FOR PAVEMENT.

Sealed Tenders plainly marked as to contents will be received at the office of the undersigned, up to **Noon of Friday, November 14th, 1913,** for the construction of pavement on King and Guelph Streets, Preston, Ont.

Plans, specifications and all information may be obtained at the office of Frank Barber, C.E., 57 Adelaide Street East, Toronto.

The lowest or any tender not necessarily accepted.

FRANK BARBER,
Engineer.

Toronto, November 5th, 1913.

(For further Tenders see pages 84 and 86.)

CANADIAN STEWART CO., LIMITED

C. P. R. BUILDING, TORONTO

INDUSTRIAL WORKS.

(Continued from page 82.)

Victoria, B.C.—The city council has authorized the construction of a concrete retaining wall on the west side of Gorge Park at a cost of $1,000.

Victoria, B.C.—Mr. J. S. MacLachlan, Dominion District Engineer, has been devising methods for the improvements to be carried out at the Canadian Collieries wharf at Union Bay, and also for river and navigation improvements at Courtenay. In addition, Mr. MacLachlan has located a site for the new wharf at Roy's Beach.

Victoria, B.C.—The city council will advertise for new tenders for the telephone pole line for the waterworks, the city engineer to put in an estimate on the whole of the work in the event of Mr. F. H. Folsom declining to accept the work at the price quoted by him last July. The tenders will be invited on the whole or part basis.

Victoria, B.C.—The council has decided by a majority vote to call again for tenders for rivetted steel pipe, the new tenders to be in by November 10, so as to give local contractors an opportunity to bid again on the specifications.

Weston, Ont.—The Weston, Water, Power, and Light Commission has decided to lay a 4-inch water main on the north side of St. John's Road at the request of the York Colonization Company. The pipe will be laid for 600 feet westerly on the road from the Weston Road.

Weston, Ont.—Water mains are being extended on several of the municipality's streets, and the contractor, G. B. Moogk, expects to have the work completed before winter frosts set in.

West Vancouver, B.C.—Tenders will be received for the construction of a breakwater at the wharf at Fourteenth Street, D.L., 237, West Vancouver, B.C. Plans and specifications may be obtained from T. F. Merrick, Esq., Manager, West Vancouver Ferry Co., Limited, West Vancouver, B.C.

West Vancouver, B.C.—The by-law to provide a wharf at the foot of Twenty-Fifth Street in Dundarave at a cost of $40,000 has been carried.

+—Winnipeg, Man.—Contracts have been awarded for the installation of water mains in St. Vital, by the city council to the GUILBAULT COMPANY, LIMITED, the contract price being $58,000. It is hoped that the first unit for 1½ miles along St. Mary's road from the boundary of St. Boniface, will be completed by next spring, when it is expected that tenders for further work, entailing an expenditure of $100,000, will be called.

MISCELLANEOUS.

Fort William, Ont.—The city council has made final arrangements for appointing an electrical inspector, and also passed a by-law such as is authorized by the hydro-electric commission for appointing its inspectors.

Lethbridge, Alta.—An agreement has been made with the city by the P. H. Rice Malting Company, of Winnipeg, by which the company will construct a malting plant and elevator at Lethbridge. The plant will cost $200,000, and will include a 100,000 bushel concrete storage elevator. The new industry has been incorporated under the name of the Lethbridge Alberta Malting Company, and will have a capital stock of $350,000.

Medicine Hat, Alta.—On the 29th of November, the people of Medicine Hat will vote upon a by-law to provide for borrowing $12,000 upon debentures to purchase additional fire apparatus for the city fire department.

▲—Ottawa, Ont.—Tenders will be received up till December 1st, 1913, for the furnishing of 15,000 small and 500 large iron posts for use on the survey of Dominion Lands, to be delivered at Edmonton on or before January 31st, 1914. Plans and specifications may be obtained from the Surveyor-General of Dominion Lands, Ottawa, Ont. Signed, L. Pereira, Secretary, Department of the Interior.

Saskatoon, Sask.—At present, local contractors are experiencing a somewhat serious cement shortage, not 100 bags being in the city. Mr. F. J. O'Leary, a prominent contractor, is engaged in the construction of a large block in the

city; and in connection with that, in the pouring of a concrete slab 17,000 square feet and 8½ inches thick, which will support 1,000 pounds to the square foot. This is the largest slab yet undertaken in Saskatoon.

Toronto, Ont.—The city has decided to build this winter a $15,000 scow, and this construction will be supervised by Mr. Charles Margerison, the new superintendent of the city's marine plant.

Toronto, Ont.—The Hydro-Electric Power Commission of Ontario will likely call for tenders within the next couple of months for impulse or special design reaction water turbines, 500-foot head, for about 2,600 feet of lapwelded or rivetted steel pipe, 30-inch diameter, from approximately 100 to approximately 500 pounds per square inch pressure; and for from 4,000 to 6,000 feet of wood stave pipe, 36-inch to 54-inch diameter, 50 pounds per square inch pressure. It is understood that this equipment will be needed in connection with the proposed development at Eugenia Falls, Ont. The Hydraulic Engineer for the Commission is H. G. Acres, Continental Life Building, Bay and Richmond Streets, Toronto, Ont.

+—**Toronto, Ont.**—The contract has been awarded by Mr. Geo. W. Gouinlock, Temple Building, Toronto, to MESSRS. T. CANNON AND SON, for the erection of a storage tank and other works for Messrs. Lever Brothers.

Toronto, Ont.—Tugs, barges, derricks, hoisting machinery, pile driving outfits, etc., will be purchased by the Canadian Stewart Company, Limited, C.P.R. Building, Toronto, in connection with its contracts for Toronto Harbor. It is understood that they are ready to receive proposals on this equipment.

+—**Vancouver, B.C.**—The contract has been awarded MESSRS. CAMPBELL BROS., for the construction of the new passenger station which the British Columbia Electric Railway Company is erecting at the south end of the Granville Street bridge as a terminal for its Lulu Island line. The substructure, consisting of heavy pile and timber work supporting the platform on the level of the bridge, was constructed last summer and work on the station proper is to be commenced by Campbell Bros. immediately, and be completed so as to allow the company to start operation into the new terminal about the first of the year. The total expenditure on the new terminal will be in the neighborhood of $40,000.

Vancouver, B.C.—The Board of Railway Commissioners, in its session held at Vancouver recently, reserved decision on the Coquitlam station site controversy, in order to give the members of the Commission an opportunity to review the previous evidence and to give the question further consideration.

Vancouver, B.C.—Tenders will be received up till November 10th, 1913, for the construction of a Sanatorium at Tranquille, B.C., of reinforced concrete. Plans and specifications may be obtained from Dr. Fagan, Provincial Board of Health Office, Victoria, B.C. Signed, S. B. Barron, Assistant Secretary, B.C. Anti-Tuberculosis Society, Vancouver, B.C.

Winnipeg, Man.—Mr. C. F. Roland, Industrial Commissioner, has left for Great Britain to take up the question of financing the proposed industrial scheme in Winnipeg. The scheme is to erect in units, buildings which will cost ultimately $10,000,000, and which are to be used by small manufacturers.

CURRENT NEWS.

Calgary, Alta.—The report of the city commissioners of Calgary shows a saving to the city of $35,000 during the past year made by the city paving plant as compared with the cost of paving by contract done in previous years. The municipal plant has laid this year 52 miles, or 140,000 square yards of pavement at an average cost of $2.15 per yard.

Drummondville, Que.—Effective proof of the commencement of construction on the St. Francis Valley Railway, formerly known as the L'Avenir and Melbourne, is furnished by the fact that engineers are surveying the line between Melbourne and Drummondville. The charter of the company was amended at the last session of the legislature extending the line so as to reach the St. Lawrence River, and it is expected that ultimately it will be built to the city of Sorel. Subsidies have been voted by both the provincial and federal governments for the 28 miles between Drummondville and Melbourne, and it is fully expected that the part of the grading on this section of the line will be made this fall.

Fredericton, N.B.—The contractors, Messrs. McLaggan, McBean and Bell have commenced operations on the construction of the new Intercolonial Railway freight sheds at Fredericton.

Galt, Ont.—The electric pumps at the waterworks station, which are being driven by a 150 h.p. auto-synchronous motor, have been found to operate satisfactorily, but until official test has been made of the pumps, they will not be taken over formally by the Water Commission.

London, Ont.—The departmentally constructed pavements in South London have been completed, and are so satisfactorily to the engineering department and Board of Works, that more concrete pavements will be constructed next year on the civic engineering plan.

Nelson, B.C.—Good progress is reported by Mr. A. J. Becker, contractor in charge of the crosscut tunnel which is being driven at the Apex mine, near New Denver. The tunnel will tap the ore at a depth of 275 feet, and it will be 417 feet in length. Already 100 feet have been driven, and it is expected to reach the vein about February 1st.

Ottawa, Ont.—The Dundonald Park well is now yielding 250 gallons of water per hour, or 6,360 gallons per day. However, boring operations will be continued for a few more feet in order to locate a greater flow.

Ottawa, Ont.—Early in October there were but eight miles of rails to be laid before the Transcontinental Railway would be connected from Moncton without intermission to the Rockies; and this gap was at a point about 200 miles east of Cochrane.

Port Arthur, Ont.—Nine new siding tracks of the C.N.R. in the south section of the yards, between the first river and the coal docks, have been completed and now furnish the company with ample storage.

Queen Charlotte, B.C.—Excellent progress is reported on the telegraph line for Graham Island, which soon will have reached Queenstown. The route of the line has been changed, and it will now run to Gold Creek, and thence to Myre Lake. It is intended eventually to connect Sandspit with Skidegate by cable across the inlet.

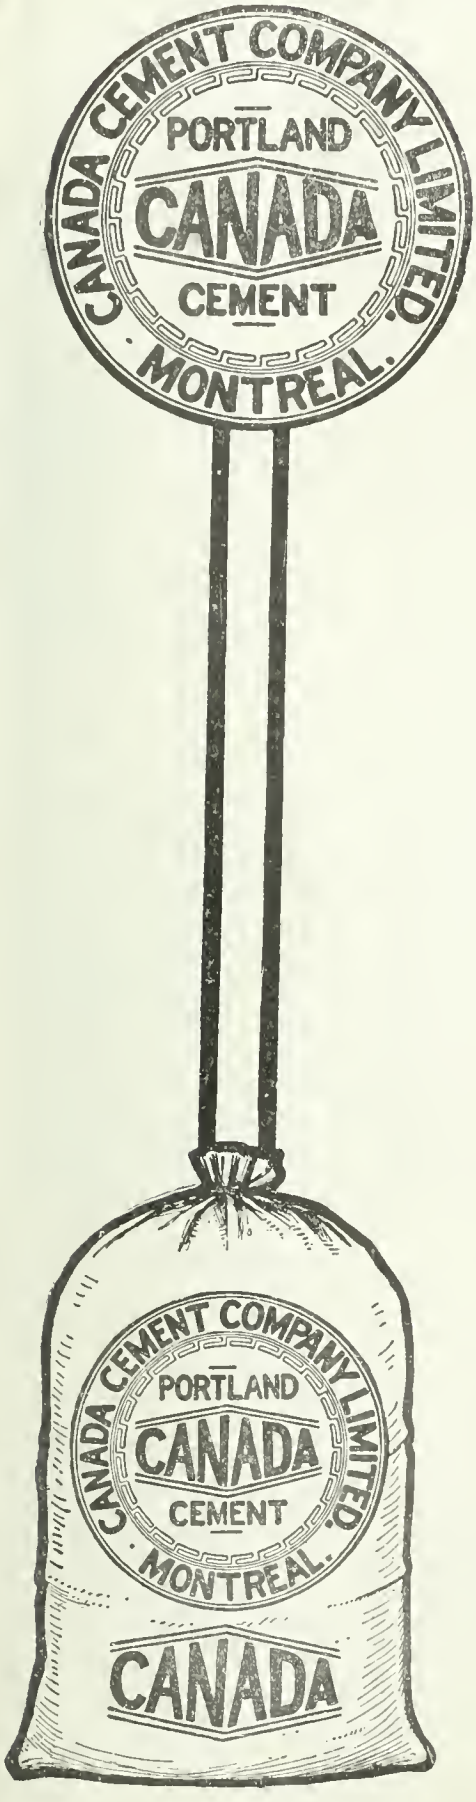
MONTREAL MARKET LETTER

Montreal, November 4.

Iron and steel men are not feeling any more cheerful as the days go by. For a long time past there has been a feeling that possibly the depression in the United States might extend across into Canada and at the moment there is fear that such a development is imminent. Car companies are beginning to feel the effects of the financial stringency—or of the lack of orders from the railway companies, whatever the reason may be for this lack. At the last annual meeting of the C.P.R., Sir Thomas Shaughnessy made a statement which is subject to the interpretation that the C.P.R. will not spend as much money in new construction and new cars in the near future as it has spent in the immediate past. This tendency in the case of the C.P.R. is hardly because of lack of money, inasmuch as the railway is exceptionally well supplied in that particular. In the case of the C.N.R., it is likely that the demands for new cars in the coming few years will be much greater than in the past, and this in all probability is the case also with the G.T.R. or G.T.P. It is thought, however, that these roads, also, will go light in the matter of ordering cars, just now, owing to the difficulty of obtaining money. Some of the car companies have been urging the Government, lately, to place orders for the I.C.R. in order to keep the car works operating. All this has a significance. Up to the present the iron and steel works have not complained of lack of orders, but there is a feeling of uncertainty over the possible effect of the lowering of the tariff in the United States. Structural steel works, including bridge companies, are all well supplied with orders, so far, and some are working overtime.

No changes in price are reported this week. The movement in pig iron is probably more active, owing to the approach of the end of the season.

PERMANENCE—



an ideal that is now attainable

THE superiority of concrete over all other materials for the building of permanent structures is now generally admitted.

The next step towards ideal construction, is to realize that for satisfactory concrete work, it is necessary to use a cement that is uniformly high-grade

CANADA Portland CEMENT

is the selection of the leading engineers, architects and contractors. Their experience has proved that in this brand they can obtain a certainty of success.

With concrete coming into more and more general use for the construction of buildings, bridges, viaducts and highways, it is vitally important that those in authority on such matters should select the best materials obtainable.

Use the cement that our best architects and engineers have selected for their most important undertakings. Select Canada Cement — it costs no more than any others.

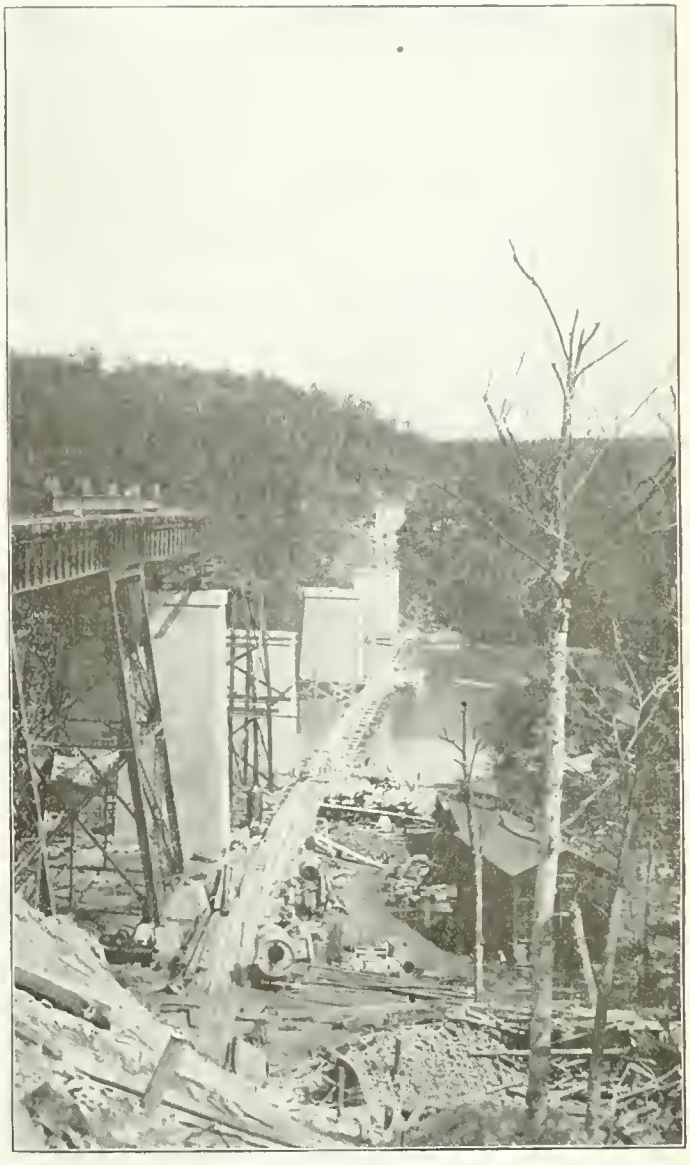
NEW INVENTION IN ELECTRIC SIGN OPERATION.

Hitherto, the operation of electric signs has been effected by the flash system; and, though now many beautiful and wonderful works of art emblazon the streets of all large cities, the amount required annually to maintain these is a matter of important consideration, and has been engaging the attention of electricians for years in efforts to invent some device or new method that will reduce the cost of operation. Mr. F. C. Brodie, of 282 Ninth Avenue, Moose Jaw, Sask., has perfected an electric sign which can be operated not only at a great decrease in expense, but also with great economy in labor. By means of slight changes in the interior mechanism of his invention, a corresponding change of letters, words, mottoes, names, or phrases can be produced in the electrical sign. Additional features of the machine are that foreign languages can be produced as easily as the English language, that pictures may be shown as readily as letters, that bulletins can also be produced effectively, since the message to be given can be changed to what is desired in a very few minutes, and, by placing a new cylinder in the machine, it may be kept in operation while the change of bulletin is being set on another cylinder; and that the controller for the sign apparatus can be placed anywhere within a building, while the sign itself might be placed upon the roof.

ONE OF OUR RECENT BRIDGE CONTRACTS

FEBRUARY, 1913



AUGUST, 1913

CONSTRUCTED IN SIX MONTHS

Substructure of 965 ft. BRIDGE—Some of these piers were carried to a depth of over 100 ft. below water level, by pneumatic caissons.

THE FOUNDATION COMPANY LIMITED

MONTREAL VANCOUVER

MARKET CONDITIONS

Montreal, November 3rd, 1913.

Bar Iron and Steel—Trade is reported active. Bar iron, $2.05 per 100 pounds; best refined horseshoe, $2.30; forged iron, $2.20; mild steel, $2.15; sleigh shoe steel, $2.15 for 1 x ⅜ base; tire steel, $2.25 for 1 x ⅜ base; toe caulk steel $3; machine steel, iron finish, $2.25.

Cement—Canadian cement is quotable, as follows, in car lots, f.o.b., Montreal:—$1.35 to $1.40 per 350-lb. bbl., in cotton bags, adding 10c. for each bag. Good bags re purchased at 10c. each. Paper bags cost 2½ cents extra, or 10c. per bbl. weight.

Chain—The market is quoted per 100 lbs. as follows:—¼-in., $5.65; 5/16-in. $4.70; ⅜-in., $4.00; 7/16-in., $3.65; ½-in., $3.45; 9/16-in., $3.45; ⅝-in., $3.35; ¾-in., $3.25; ⅞-in., $3.15; 1-in., $3.05.

Explosives and Accessories—Dynamite, 50-lb. cases, 40 per cent. proof, 15c. in single case lots, Montreal; 50 per cent., 16½c., and 60 per cent., 18c. Blasting powder, 25-lb. kegs, A, $1.85, and B, $2.35 per keg. Special quotations on large lots of dynamite and powder. Detonator caps, case lots, containing 5,000, 75c. per 100; double strength, $1, and broken lots higher; electric blasting apparatus:—Batteries, 1 to 10 holes, $13.50; 1 to 10 holes, $20.50; 1 to 50 holes, $41. Wire, leading, 1c. per foot; connecting, 50c. per lb. Fuses, platinum, single strength, per 100 fuses:—4-ft. wires, $3; double strength, $3.50; 6-ft. wires, $3.54, and double, $4.04; 8-ft. wires, $4.08, and double, $4.58; 10-ft. wires, $5, and double, $5.12.

Galvanized Iron—The market is steady. Prices, basis, 28-gauge, are:—Queen's Head, $4.40; Colborne Crown, $4.20; Apollo, 10¾ oz., $4.30. Add 25c. per 100 lbs. to above figures for less than case lots; 26-gauge is 25c. less than 28-gauge, American 28-gauge and English 26 are equivalents, as are American 10¾ oz., and English 28-gauge.

Galvanized Pipe—(See Pipe, Wrought and Galvanized)

Iron.—Following prices are on dock. No. 1 Summerlee, $21.75 per ton; selected Summerlee, $21.25; soft Summerlee, $20.75 per ton. No. 3 Middlesboro irons are about $19 per ton. Carron iron number for number and grade for grade is quoted about the same price as Summerlee. Canadian iron sells here at about $19 to $19.50 per ton, on track.

Lath—See Lumber, etc.

Lumber, etc.—Prices on lumber are for car lots, to contractors, at mill points. Red pine, mill culls out, $20 to $22 per 1,000 feet; white pine, mill culls, $20. Spruce, 1-in. by 4-in. to 6-in., $21; 1 x 7 to 9, $24 per 1,000 ft.; mill culls, $18. Hemlock log run, culls out, $19. Railway Ties, Standard Railway Ties, hemlock or cedar, 56 to 55c. each. Telegraph poles; seven-inch top, cedar poles, 25-ft. poles, $2, each; 30 ft., $3.75; 35-ft., $4.50 each; 40-ft., $6; 45 to 50, 16c. per foot. Laths: Quotations per 1,000 laths, at manufacturers' points. Spruce 4-ft. x 1½ in., mill run, $3 to $3.25; pine, 4-ft. x 1⅜-in., mill run, $3.25 to $3.75. Shingles: Cedar shingles, same conditions as laths, X, $2 10; XX, $2.40; XXX, $2.80.

Pipe—Cast Iron—The market is dull and rather easy:—$34 for 6 and 8-inch pipe and larger; $35 for 40-inch at the foundry. Pipe, specials, $3 per 100 pounds. Gas pipe is quoted at about $1 more than the above.

Pipe—Wrought and Galvanized—Demand is fair and the market steady: —¼-inch $5.50, with 63 per cent. off for black, and 48 per cent. off for galvanized; ⅜-inch, $5.50, with 63 per cent. off for black, and 48 per cent. off for galvanized; ½-inch, $8.50, with 69 per cent off for black, and 59 per cent. off for galvanized. The discount on the following is 72½ per cent. off for black, and 62½ per cent. off for galvanized; ¾-inch, $11.50; 1-inch, $16.50; 1¼-inch, $22.50; 1½-inch, $27. On the following the discount is 72½ per cent. for black and 62½ per cent. for galvanized:—2-inch, $36; 2½-inch, $57.50, and 3-inch $75.50; 72½ per cent. off for black, and 62½ per cent. off for galvanized: 3½-inch $95 4-inch, $1.08.

Toronto, November 5th, 1913.

The following are the wholesale prices for Toronto, where not otherwise explained, although for broken quantities higher prices are quoted:

Axes.—Standard makes, double bitted, $6 to $10; single bitted, per dozen, $7.50 to $9.

Bar Iron—$2.25 base, per 100 lbs., from stock to wholesale dealer. In enormous demand.

Bar Mild Steel—Per 100 lbs., $2.25. Sleigh shoe and other take same relative advance.

Boiler Plates—½-inch and heavier, $2.20. Boiler heads 25c. per 100 pounds advance on plate. Tank plate, 3-16-inch, $2.40 per 100 pounds.

Boiler Tubes—Orders continue active. Lap-welded, steel, 1¾-inch, 10c. 1½-inch, 9c. per 10-ft.; 2-inch, $8.50 to $9; 2¼-inch, $10; 2½-inch, $10.50; 3-inch, $12.10; 3½-inch, $15; 4-inch, $19.

Bricks—In active movement. The price is $11.50 for grey stock, $12 for red stock. Don Valley pressed brick are in request. No. 1 dry pressed and buff bricks are worth $18 delivered and $17 at works per 1,000. Port Credit Brick Company's prices are as follows, f.o.b., Port Credit: Wire cut bricks, $10 per M.; pressed bricks, $14 to $15 per M., three grades.

Broken Stone—Lime stone, good hard, for roadways or concrete, f.o.b., quarries 70 to 75c. per ton of 2,000 lbs., either 1-inch, 10c., 2-inch, or larger, price all the same. Rubble stone, 55c. per ton, Schaw station, and a good deal moving. Broken granite is selling at $3 per ton for good Oshawa, or Quebec Province. At Washago, $2.50 per ton for small, and $1.15 for large freight to Toronto 60 cents.

Cement—Demand very brisk, and prices maintained. In large quantities the price is $1.50, sacks, 40c. extra; car lots $1.55, sacks extra; city dealers ask $1.85, sacks extra. Prices remain firm.

Copper Ingot—The market is lower at 15½ to 16c., sheet copper case (16 oz. soft), 22½c. to 24½c. per lb.

Detonator Caps—75c. and $1 per 100; case lots, 5,000, 20 per cent. off.

Dynamite—The prices for this explosive vary according to the percentage of nitro-glycerine compounded in the mixture and are as follows, f.o.b., Toronto:—40 per cent., 16¼ cents per pound, 1 to 9-case lots, 50 lbs. to case. For each additional 10 per cent. nitro-glycerine add 1½c. per hundred. For 10-case lots and over deduct ½ cent. For 20-case lots and over deduct 1 cent. For 40-case lots and over deduct 1½ cents.

Fuses—Electric Blasting—Double strength, $3.50 per hundred, advance 5½c. per hundred for each 2-in. wire additional. Single strength, $3 per hundred, advance 5½c. per hundred for each 2-in. wire additional.

Iron Chain—¼-inch, $5.75; 5-16-inch, $5.15; ¾-inch, $4.15; 7-16-inch, $3.95; ½-inch, $3.75; 9-16-inch, $3.70; 5-8-inch, $3 55; ¾-inch, $3.45; ⅞-inch, $3.40; 1-inch, $3.40 per 100 lbs.

Iron Pipe—Quotations are changed as follows:—Black pipe, ¼-inch, $2.04; ⅜-inch, $2.04; ½-inch, $2.72; ¾-inch, $3.16; 1-inch, $4.54; 1¼-inch, $6.19; 1½-inch, $7.43; 2-inch, $9.90; 2½-inch, $15.80; 3-inch, $20.75; 3½-inch, $26.13; 4-inch, $29.70; 5-inch, $40 60; 6-inch, $52.64. Galvanized Pipe, ¼-inch, $2.86; ⅜-inch, $2.86; ½-inch, $3.57; ¾-inch, $4.31; 1-inch, $6.19; 1¼-inch, $8.44; 1½-inch, $10.13; 2-inch, $13.50; 2½-inch, $21.56; 3-inch, $28.31.

Lead—Firmer, $5.25 to $5.50.

Pig Iron—We quote Clarence at $24 for No. 3; Cleveland, $24; Summerlee, $27; Hamilton quotes $22; Midland, No. 1, $22; No. 2, $21.50. There is considerable enquiry for 1912.

Pitch and Tar—Pitch, unchanged at 75c. per 100 lbs. Coal tar, $3.75 per barrel.

Roofing Slate—Most of the slate used in Canada comes from Pennsylvania or Maine, the Canadian supply being slender and mostly from the Rockland quarries of the Eastern Townships in Quebec. There is a great variety of sizes and qualities, so that it is difficult to indicate prices. But Jackson Bangor, 10 x 16 may be quoted at $6.75 per square of 100 square feet f.o.b. cars, Toronto; seconds, 50c. less. Mottled, $8; green $8, with a prospect of advance. Dealers are fairly busy.

Sand—Sharp, for cement or brick work, $1.15 per net yard f.o.b., cars, Toronto siding.

Sewer Pipe—

	4-in.	6-in.	9-in.	12-in.	24-in.
Straight pipe; per foot.....	$0 25	$0.40	$0.65	$1.00	$ 3.25
Single junction, 1 or 2 ft. long ...	1.00	1.60	2.60	4.00	13.00
Double junctions.....	1.25	2.00	3.25	5.00	16.25
Increasers and reducers.....	....	1.60	2.60	4.00	13.00
P. & H. H. traps	2.00	3.20	6.50	15.00	....
Bends	0.75	1.20	1.95	3.00	9.75

Above is the October list as changed. The retail price is less 65 per cent. off these figures on all sizes 9 inches and under, or less 60 per cent. off these figures on anything over 9 inches. For car-loads a greater discount.

Steel Beams and Channels—Active—We quote:—$2.65 to $3 cut to length per 100 lbs., according to size and quantity; angles, 1½ by 3-16 and larger, $2.50 to $2.75; tees, $2.75 to $3 per 100 lbs. Extra for smaller sizes of angles and tees.

Sheet Copper—22c. per lb.

Sheet Steel—American Bessemer, 10-gauge, $2.75; 12-gauge, $2.80; 14-gauge, $2.50; 17, 18, and 20-gauge, $2.75; 22 and 24-gauge, $2.80; 26-gauge, $2.85; 28-gauge, $3. A very active movement is reported at unchanged prices.

Sheets, Galvanized—Apollo Brand—Sheets, 6 or 8 feet long, 30 or 36 inches wide: 10-gauge, $3; 12-14-gauge, $3; 16, 18, 20, $3.30; 22-24, $3,40; 26, $3.50; 28, $3.90; 29, $4.10; 10¾, $4.10 per 100 lbs. Fleur de Lis—28-gauge, $4.25; 26, $4.05 per 100 lbs. Active and firm at these prices.

Tin—The combination seems to hold, and the price, 45 to 50c., lower.

Tool Steel—Jowett's special pink label, 10½c. Cammel-Laird, 16c "H.R.D." high speed tool steel, 65c.

Tank Plates—3-16 inch, $2.40 per 100 lbs.

Zinc—Spelter—Good demand, and the feeling strong. Light stock; excellent demand. We quote very firm at $6 to $6.50 per cwt.

Winnipeg, November 4th, 1913.

Anvils—Per pound, 11½ to 12½c.; Buckworth anvils, 80 lbs. and up, 10¾ to 10¾c., anvil and vise combined, each $5.50.

Bar Iron—$2.50 base.

Bars—Crow, $4.50 per 100 pounds.

Beams and Channels—$3 to $3.10 per 100 up to 15-inch, 4, 30, 41, 50, 118, 119, 172, 132, 145, 176.

Brick—Kiln run per M, $13; sewer pipe per M, $14; chimney per M, $14; veneer per M, $15; pressed per M, $25 to $50; enameled per M, $100; sand lime per M, $13.

Cement, Portland—$2.40 to $2.50 per barrel.

Chain—Coil, 3-16-in., $10; ¼, $7.25; 5-16, $5.85; ⅜, $5; 7.16, $4.75; ½, $4.50; 9-16, $4.50; ⅝, $4.40; ¾, $4.25. Logging, 5-16, 6½c.; ⅜, 5¾c. Tie out, 70 and 10 per cent.

Copper—Tinned, boiler, 26½c., planished, 29½c.; boiler and T. K. pits, plain, tinned, 45 per cent. discount.

Dynamite—$11 to $13 per case.

Galvanized Iron—Apollo, 10¾, $4.80; 28, $4.60; 26, $4.20; 22, $4.10; 24, $4.10; 20 $4; 18, $3.95; 16, $3.90. Queen's Head, 28, $4.90; 26, $4.70; 24, $4.30; 22, $4.20; 20, $4.10 per cw

Iron—Swedish iron, 100 lbs., $4.75 base; sheet, black, 14 to 22 gauge, $3.75; 24-gauge, $3.90; 26-gauge, $4; 28-gauge, $4.10. Galvanized—American 18 to 20-gauge, $4.40; 22 to 24-gauge, $4.65; 26 gauge, $4.65; 28-gauge, $4.90; 30-gauge, $5.15 per 100 lbs. Queen's Head, 22 to 24-gauge, $4.65; 26-gauge English, or 30-gauge American, $4.90; 30-gauge American $5 15; Fleur de Lis, 22 to 24-gauge, $4.50; 28-gauge American, $4.75; 30-gauge American, $5; bar, $2.50 base.

Pipe—Iron, black, per 100 feet, ¼-inch, $2.40; ⅜-inch, $2.55; ½-inch, $3-35; ¾-inch, $4; 1-inch, $5.75; 1¼-inch, $7 80; 1½-inch, $9.35, 2-inch, $12.50; galvanized—½-inch $4.35; ¾-inch, $5.20; 1-inch, $7.55; 1¼-inch, $10.25; 1½-inch, $12.25; 2-inch, $16.40. Lead, 7.60 per cent., full coil.

Pitch—Pine, $6.50 per barrel, in less than barrel lots, 4c. per lb.; roofing pitch $1 per cwt.

Steel Plates, Rolled—3-16-in., $3.35 base; machinery, $3 base; share, $4.50 base; share crucible, $5.50; cast share steel, $7.50; toe caulk, $4.50 base tire steel, $3 base; cast tool steel, lb., 9 to 12½c.

Tool Steel—8½ to 15c. per pound.

A weekly paper for engineers and engineering-contractors

STRESSES IN CIRCULAR PIPES.

WITH SOME NOTES ON THE DESIGN OF LARGE WATER CONDUITS—A CALCULATION OF STRESSES DUE TO INTERNAL WATER PRESSURE, WEIGHT OF THE SHELL, AND BACK-FILL—CIRCULAR PIPE UNSUITED FOR CASES OF LARGE DIAMETER PIPE AND LOW PRESSURE HEAD, OWING TO THE RESULTING BENDING MOMENTS

By T. H. HOGG, B.A.Sc., A.M. Can. Soc. C.E.,

Assistant Hydraulic Engineer, Hydro-Electric Power Commission of Ontario, Toronto.

The analysis of the stresses in circular pipes due to the weight of the material in the pipes themselves, to internal and external water pressures, and to different kinds of loading, is a subject to which little attention has been devoted in engineering literature.

When the pipes are relatively small in diameter, the conditions are such as yield to simple approximate methods of investigation. With the larger sizes of conduits and pipes now being used so extensively in water supply and water power systems, however, the question of the weight of the shell itself, and the differences in pressure at the top and bottom of the pipe when conveying water in a horizontal position, become exceedingly important.

This paper is presented in the hope that it will afford some aid to the engineer in the design of such conduits. The results of the analyses contained in it were arrived at while the writer was working under the direction of Mr. R. D. Johnson, of Niagara Falls. The system followed in the development of the theory of the stresses due to water pressure is along similar lines to the work of C. W. Filkins and E. J. Fort, who developed the stresses in circular rings due to the weight of the rings themselves, and due to external water pressure. Their work is published in the "Transactions of the Association of Civil Engineers of Cornell University," for 1896.

The following discussion takes up the analysis of the stresses in circular conduits due to internal water pressure. The method of combining the stresses due to the weight of the shell and to the water pressure is reviewed; the question of the design of large conduits for the carrying of water is dealt with, and the equilibrium shape as the logical one, in preference to the circular, is described.

Stresses Due to Internal Water Pressure.—It is usually assumed in figuring the stresses due to internal water pressure in circular pipes or conduits, lying horizontally, that it is quite sufficient to take into account only the tension induced in the shell, and that the bending moment may be neglected. This is only true when the pressure head is infinite and may be grossly in error when the pressure head is small, and the diameter of the pipe relatively large. When the latter condition exists there is a greater pressure at the bottom than at the top, and this causes large bending moments in the shell.

Throughout this discussion the ring is assumed supported on a knife edge, and water pressure is assumed level with the crown of the pipe. The analysis also assumes a thin ring of homogeneous material, having a constant modulus of elasticity, and that the changes from

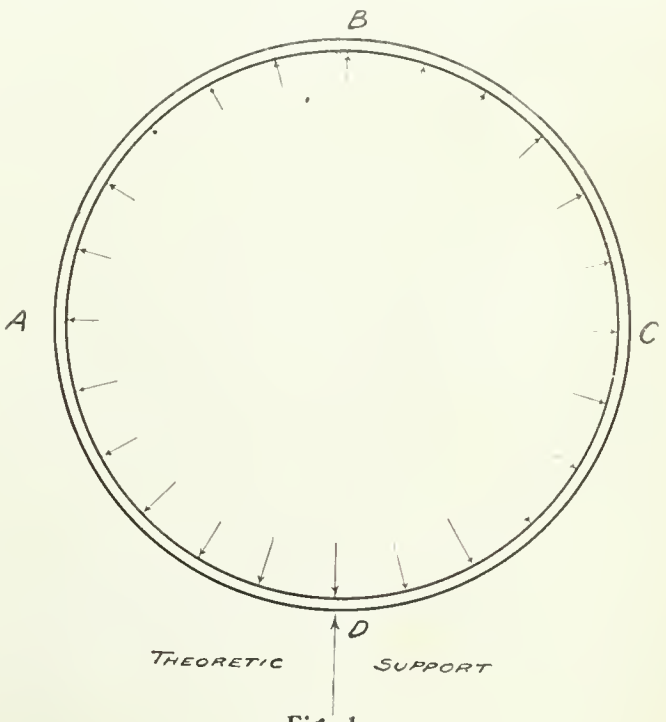

Fig. 1.

a circular form will have little effect upon the dimensions of the ring.

These assumptions are merely to facilitate the application of theory. When the results have been obtained, practical considerations which affect these considerations will be discussed.

The following nomenclature will be used throughout the paper:

H = head of water above top of pipe.
r = radius of circular pipe.
M = bending moment in pipe.
M_B = bending moment in pipe at top.
M_D = bending moment in pipe at bottom.
M_{max} = bending moment in pipe at maximum point on side.
T = tension in pipe.
T_B = tension in pipe at top.
T_D = tension in pipe at bottom.
ϕ = angle to different points (expressed in radians).
ϕ_{max} = angle to maximum bending moment point on side.
ϕ_U = angle to upper node point (point of no bending moment).
ϕ_L = angle to lower node point (point of no bending moment).
γ = weight of cubic foot of water.
J = shear at any point.
J_B = shear at top.
J_D = shear at bottom.
d_ρ = arm of bending moment.
d_o = arm of the bending moment at top of pipe.

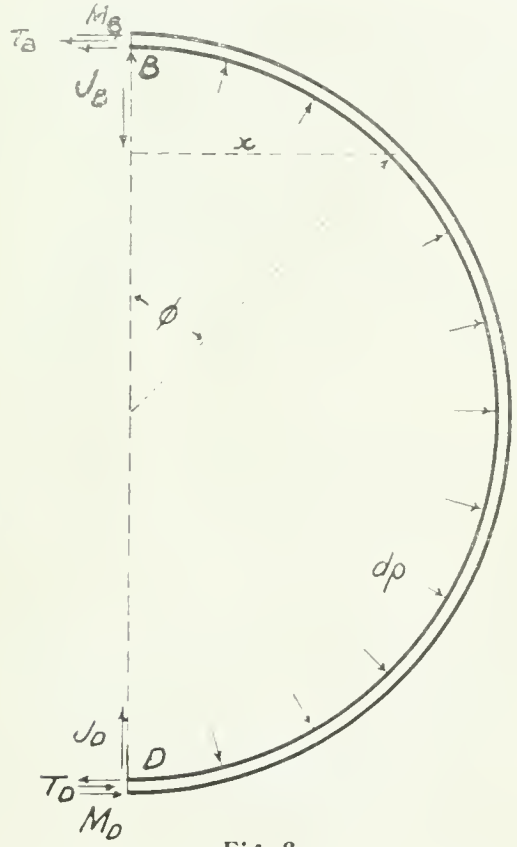

Fig. 2.

We will assume that the reader is familiar with the three general formulae for arch ribs, viz.,

$$\int_D^B \frac{Mds}{EI} = \int_D^B d\phi; \qquad \int_D^B \frac{Myds}{EI} = \int_D^B dx;$$

$$\int_D^B \frac{Mxds}{EI} = \int_D^B dy.$$

The ring is a continuous curved beam to which these situations will apply.

The forces acting upon the pipe may be appreciated by looking at Fig. 1. If we cut the pipe at B and D and consider the forces acting on the section to the right, we obtain the system of forces shown in Fig. 2.

Taking the centre of moments at the neutral axis at D, we obtain:

$$M_D = M_B - 2T_B r + \int_o^\pi r(1 - \cos\phi)\, dp \sin\phi$$

Now,

$dp = \gamma r^2 (1-\cos\phi)\, d\phi$; and,

$\sin\phi\, dp = \gamma r^2 (1-\cos\phi) \sin\phi\, d\phi$.

Therefore,

$$M_D = M_B - 2T_B r + \int_o^\pi \gamma r^3 (1-\cos\phi) \sin\phi\, d\phi.$$

Integrating, we obtain:

$$M_D = M_B - 2T_B r + 2\gamma r^3.$$

Now, consider as a free body that portion of pipe shown in Fig. 3.

$$EI\Delta y = \int Mxds; \; ds = rd\phi = rd\theta;$$

$$-M = M_B - T_B y + \int_o^B pdsx;$$

$$pds = \gamma r^2 (1-\cos\theta)\, d\theta;$$

$$x = r \sin(\phi - \theta);$$

$$y = r(1-\cos\phi).$$

Therefore,

$$-M = M_B - T_B r (1-\cos\phi) + \int_o^\phi \gamma r^3 (1-\cos\theta) \sin(\phi-\theta)\, d\theta;$$

$$= M_B - T_B r + T_B r \cos\phi + \gamma r^3 \int_o^\phi (1-\cos\theta) \sin(\phi-\theta)\, d\theta,$$

$$= M_B - T_B r + T_B r \cos\phi + \gamma r^3 (1-\cos\phi - \tfrac{1}{2}\phi \sin\phi).$$

Therefore,

$$EI\Delta y = \int Mxds = \int Mr^2 \sin\phi\, d\phi,$$

$$= \int_o^\pi \left[(M_B r^2 - T_B r^3 + \gamma r^5) \sin\phi\, d\phi + (T_B r^3 - \gamma r^5) \sin\phi \cos\phi\, d\phi - \tfrac{1}{2}\gamma r^5 \phi \sin^2\phi\, d\phi \right]$$

Solving the above equation we obtain:

$$EI\Delta y = -2(M_B r^2 - T_B r^3 + \gamma r^5) + \frac{\gamma r^5 \pi^2}{8};$$

also, $EI\Delta x = \int_D^B M(ds)y = 0$, since B has not moved horizontally, and since its tangent is horizontal.

Now, $y = r(1-\cos\phi)$; $ds = rd\phi$.

Therefore, $EI\Delta x = r\int_o^{\pi r} Mds - r^2 \int_o^\pi M \cos\phi\, d\phi$

i.e., $0 = r\int_o^{\pi r} Mds - r^2 \int_o^\pi M \cos\phi\, d\phi$.

Substitute value of M found above and solve.

Therefore, $-\int_o^\pi M \cos\phi\, d\phi = \int_o^\pi \left[(M_B - T_B r + \gamma r^3) \cos\phi\, d\phi + (T_B r - \gamma r^3) \cos^2\phi d\phi - \tfrac{1}{2}\gamma r^3 \phi \sin\phi \cos\phi\, d\phi \right]$.

Therefore, $-\int_o^\pi M \cos\phi\, d\phi = \frac{\pi}{2}\left\{ T_B r - \gamma r^3 \right\} + \frac{\gamma r^3 \pi}{8}$;

or, $\int_D^B Myds = \frac{\pi r^3}{2}\left\{ T_B - \frac{3\gamma r^2}{8} \right\} = 0$;

and, therefore, $T_B = \frac{3}{4}\gamma r^2$.

Now, $\int_D^B M ds = 0 = \int_0^{\pi} \left[M_B r d\phi - T_B r^2 (d\phi - \cos\phi\, d\phi) + \gamma r^3 (d\phi - \cos\phi\, d\phi - \frac{1}{2}\phi \sin\phi\, d\phi) \right]$;

Whence, solving the above,

$$M_B = T_B r - \frac{1}{2}\gamma r^3.$$

Therefore, $M_B = \frac{\gamma r^3}{4}$

Now, $M_D = M_B + 2\gamma r^3 - 2T_B r$

$$= \frac{\gamma r^3}{4} + 2\gamma r^3 - \frac{3\gamma r^3}{2}$$

$$= \frac{3}{4}\gamma r^3$$

Now, $-M = M_B - T_B r + T_B r \cos\phi + \gamma r^3 \left(1 - \cos\phi - \frac{1}{2}\phi\sin\phi\right) = \gamma r^3 \left(\frac{1}{2} - \frac{1}{4}\cos\phi - \frac{1}{2}\phi\sin\phi\right)$,

which is the general expression for the bending moment.

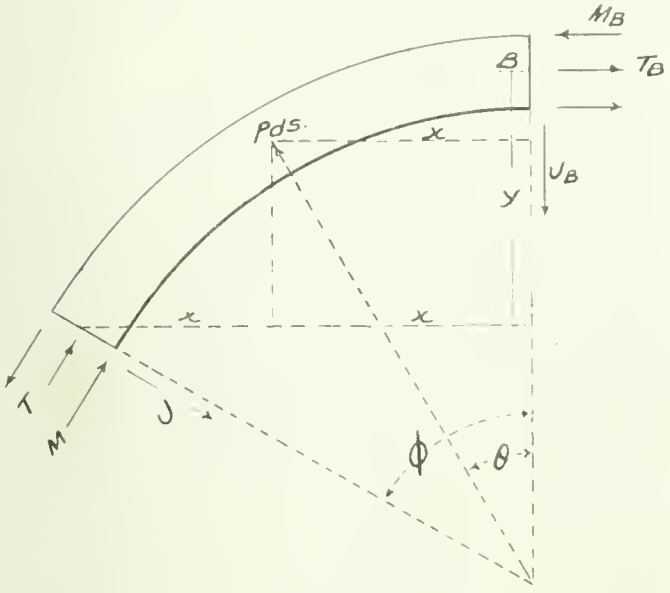

Fig. 3.

To find the shortening of the vertical diameter, substitute the values of M_B and T_B in the equation:

$$EI\Delta y = -2\,(M_B r^2 - T_B r^3 + \gamma r^5) + \frac{\gamma r^5 \pi^2}{8}.$$

We obtain, $EI\Delta y = -\gamma r^5 + \frac{\gamma r^5 \pi^2}{8}$,

$$\Delta y = \frac{\gamma r^5}{EI}\left(\frac{\pi^2}{8} - 1\right) = +.2337\,\frac{\gamma r^5}{EI}.$$

To find the lengthening of the horizontal diameter,

$$EI\Delta x = \int_A^B M\,(ds)\,y.$$

$$\therefore -EI\Delta x = \int_0^{\frac{\pi}{2}} \left[(M_B - T_B r + \gamma r^3) r^2\,(1 - \cos\phi)\,d\phi + (T_B r - \gamma r^3)\, r^2 (\cos\phi - \cos^2\phi)\,d\phi - \frac{1}{2}\gamma r^5\,(1\text{-}\cos\phi)\,\phi\sin\phi\,d\phi \right].$$

Solving, $-EI\Delta x = \frac{\gamma r^5}{4}(1.5\pi - 5)$,

$$= -.0719\,\gamma r^5,$$

Therefore, $\Delta x = .0719\,\frac{\gamma r^5}{EI}$.

The whole change in horizontal diameter,

$$= 2\Delta x = .1438\,\frac{\gamma r^5}{EI}.$$

In order to find the value of ϕ where the moment is a maximum, place $\frac{dM}{d\phi} = 0$.

Therefore, $T_B r\, d\cos\phi - \gamma r^3 d\cos\phi - \frac{1}{2}\gamma r^3\, d\phi \sin\phi = 0$.

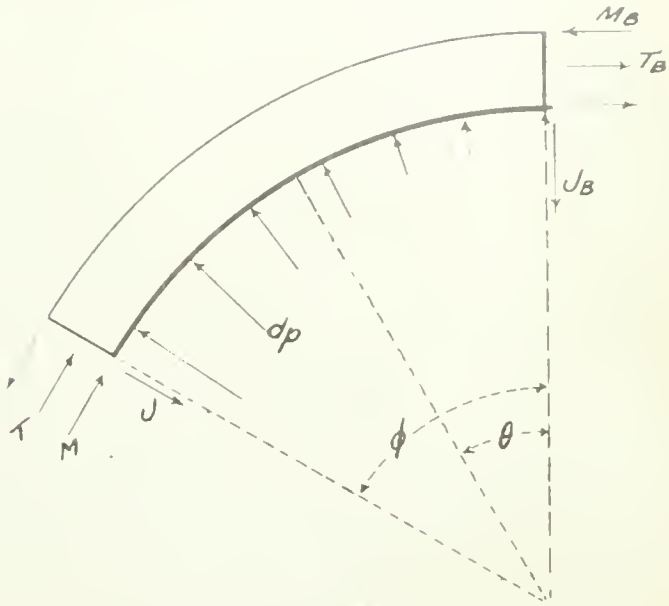

Fig. 4.

Differentiating and simplifying, we obtain:

$$\phi\cot\phi = -\frac{1}{2},$$

$$-2\phi = \tan\phi.$$

By trial we find $\phi = 105° - 13' - 45.4''$; also $\phi = 0$.

Now when $\phi = 0$, the maximum moment $M_B = \frac{\gamma r^3}{4}$.

When $\phi = 105° - 13' - 45.4''$ substitute in the expression for the moment,

$$-M = M_B - T_B r + T_B r \cos\phi + \gamma r_3 (1 - \cos\phi - \frac{1}{2}\phi\sin\phi),$$

and we obtain,

$$M = -.3203\,\gamma r^3 .$$

Assembling and comparing the values of the moments found, we see that $M_B = +\frac{\gamma r^3}{4}$; $M_D = +\frac{3\gamma r^3}{4}$,

and $M_{max} = -.3203\,\gamma r^3$.

Therefore, we see that the moment of the stress couple changes sign (i.e., passes through zero) between M_B and M_{max}, and between M_{max} and M_D.

Place M in the general equation, equal to zero, and solve for ϕ.

$$\gamma r^3 \left(\frac{1}{2} - \frac{1}{4}\cos\phi - \frac{1}{2}\phi\sin\phi\right) = M = 0.$$

Therefore, $\phi \sin\phi + \frac{1}{2}\cos\phi = 1$,

or, $\phi = 50° - 36' - 45''$,
also, $\phi = 146° - 19' - 25''$.

Now, considering Fig. 4, we see that the value of $dp = \gamma r^2 (1\text{-}\cos\theta)\, d\theta$.

Therefore, the sum of the vertical components of all the dp's between o and ϕ

$$= \int_0^{\phi} dp \cos\theta = \int_0^{\phi} \gamma r^2 (1\text{-}\cos\theta)\cos\theta\, d\theta,$$

$$= \gamma r^2 \left(\sin\phi - \frac{1}{2}\phi - \frac{1}{4}\sin 2\phi\right).$$

And the sum of the horizontal components of all the dp's between o and ϕ

$$= \int_0^{\phi} dp \sin\theta = \int_0^{\phi} \gamma r^2 (1\text{-}\cos\theta)\sin\theta\, d\theta,$$

$$= -\gamma r^2 \left(\cos\phi - 1 + \frac{\sin^2\phi}{2}\right)$$

In Fig. 4 place the vertical components of the acting forces equal to zero.

Therefore,

$$J\cos\phi + T\sin\phi = \gamma r^2 \left(\sin\phi - \frac{1}{2}\phi - \frac{1}{2}\sin\phi\cos\phi\right).$$

Placing the horizontal components equal to zero,

$$J\sin\phi - T\cos\phi = \frac{3}{4}\gamma r^2 - \gamma r^2\cos\phi + \gamma r^2 - \frac{1}{2}\gamma r^2 \sin^2\phi$$

Solving these equations for T and J, we obtain:

$$T = \gamma r^2 \left(1 - \frac{1}{2}\phi\sin\phi - \frac{1}{4}\cos\phi\right).$$

$$J = \gamma r^2 \left(\frac{1}{2}\phi\cos\phi + \frac{1}{4}\sin\phi\right).$$

The above discussion has assumed that the pipe is just filled to the top with water. It is easy to see that the bending moments are not affected by the water pressure after the top is passed. In other words, the bending moments induced in the shell are caused by the difference in pressure between the top and any point on the shell chosen; and this difference remains constant for any head above the top. The tension in the shell, however, varies directly with the head, and is equal to $H\gamma r$, where H is the head on the top of the pipe.

This amount must be added to the above obtained value of the tension to obtain the general expression.

Formulae for Stresses Due to Internal Water Pressure

$$M = -\gamma r^3 \left(\frac{1}{2} - \frac{1}{4}\cos\phi - \frac{1}{2}\phi\sin\phi\right),$$

$$T = H\gamma r + \gamma r^2 \left(1 - \frac{1}{4}\cos\phi - \frac{1}{2}\phi\sin\phi\right),$$

$$J = \gamma r^2 \left(\frac{1}{2}\phi\cos\phi + \frac{1}{4}\sin\phi\right),$$

$$M_B = \frac{1}{4}\gamma r^3,$$

$$M_D = \frac{3}{4}\gamma r^3,$$

$$M_{max} = -.3203\ \gamma r^3,$$

$$T_B = H\gamma r + \frac{3}{4}\gamma r^2,$$

$$T_D = H\gamma r + \frac{5}{4}\gamma r^2,$$

$$\phi_{max} = 105° - 13' - 45''.4,$$

$$\phi_U = 50° - 36' - 45'',$$

$$\phi_L = 146° - 19' - 25'',$$

$$\triangle_x = .0719\ \frac{\gamma r^5}{EI},$$

$$\triangle_y = .2337\ \frac{\gamma r^5}{EI};$$

To show the results clearly, let us plot a bending moment diagram. We can always express the bending moment in terms of the tension multiplied by the arm of the moment. Therefore, if we divide the bending moment at any point by the tension at the same point, we obtain the arm of the bending moment at that point.

Let $d\rho = \frac{M}{T}$ = arm of the bending moment,

$$= \frac{-\gamma r^3 \left(\frac{1}{2} - \frac{1}{4}\cos\phi - \frac{1}{2}\phi\sin\phi\right)}{\gamma r \left\{H + r\left(1 - \frac{1}{4}\cos\phi - \frac{1}{2}\phi\sin\phi\right)\right\}},$$

$$= \frac{-r\left(\frac{1}{2} + k\right)}{\frac{H}{r} + r + k}, \text{ where } k = -\frac{1}{4}\cos\phi - \frac{1}{2}\phi\sin\phi.$$

Plotting the values of $d\rho$ readily, for different values of ϕ, we can represent the bending moments as shown in Fig. 5. This curve is the equilibrium polygon for the assumed conditions.

The arm of the bending moment at the top of the pipe, $d_o = \frac{M_T}{T_T} = \frac{\frac{1}{4}\gamma r^3}{H\gamma r + \frac{3}{4}\gamma r^2}$,

$$= \frac{\frac{1}{4}r^2}{H + \frac{3}{4}r},$$

Stresses due to the Weight of the Shell.—The analysis of the stresses due to the weight of the material in the shell of the pipe is similar to the method we have just employed. As this case has been developed in the paper by Mr. C. W. Filkins and Mr. E. J. Fort, referred to in the introduction to this discussion, we will not repeat the discussion here. The following are the formulae deduced by them for the stresses due to the weight of the shell.

$$M = pr^2 \left(\phi\sin\phi + \frac{1}{2}\cos\phi - 1\right),$$

$$T = pr \left(\phi\sin\phi - \frac{1}{2}\cos\phi\right),$$

$$J = pr \left(\phi\cos\phi + \frac{1}{2}\sin\phi\right),$$

$$M_B = \frac{1}{2}\, pr^2,$$

$$M_D = \frac{3}{2}\, pr^2,$$

$$M_{max} = -.64076\ pr^2,$$

$$T_B = \frac{1}{2}\, pr = T_D,$$

$$\phi_{max} = 105° - 13' - 45.4'',$$

$$\phi_U = 50° - 36' - 45'',$$

$$\phi_L = 146° - 19' - 25'',$$

$$\triangle x = .1438\, \frac{pr^4}{EI},$$

$$\triangle y = .4674\, \frac{pr^4}{EI}.$$

The only new symbol here is, p, which represents the weight of a unit length of the pipe.

Stresses due to Back Fill.—The stresses due to an external concentrated vertical load on the crown of a circular pipe whose thickness is small as compared to its diameter, have been investigated by several writers.

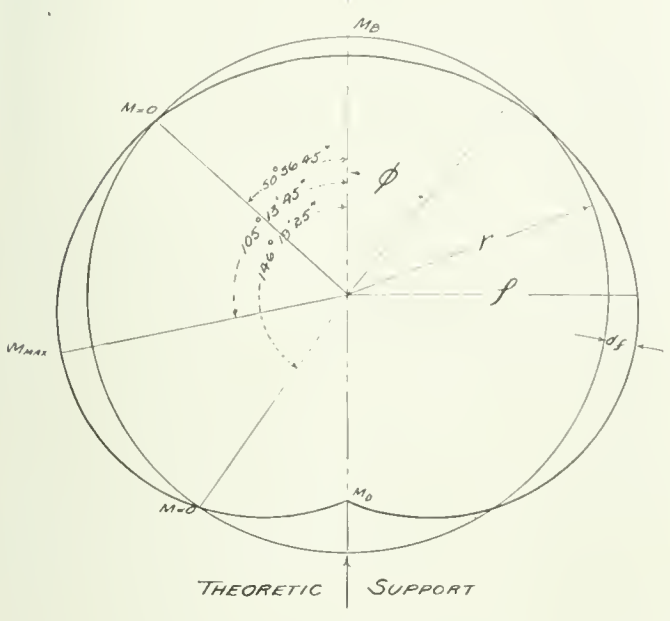

Fig. 5.

Probably the clearest exposition of this case together with the cases of a distributed vertical load, and distributed vertical and horizontal loads is given in Bulletin No. 22, University of Illinois Engineering Experiment Station. "Tests of Cast Iron and Reinforced Concrete Culvert Pipe," by A. N. Talbot. The reader is referred to this discussion.

The bending moment at the crown due to a concentrated vertical load P is equal to $M_B = .159\ Pd$, where d is the mean diameter of the pipe.

The bending moment at the crown due to a vertical load distributed uniformly over the horizontal projection of the ring is equal to $M_B = \frac{1}{16}\, wd.$, where d is the mean diameter of the ring and w is the total load on a ring of unit length.

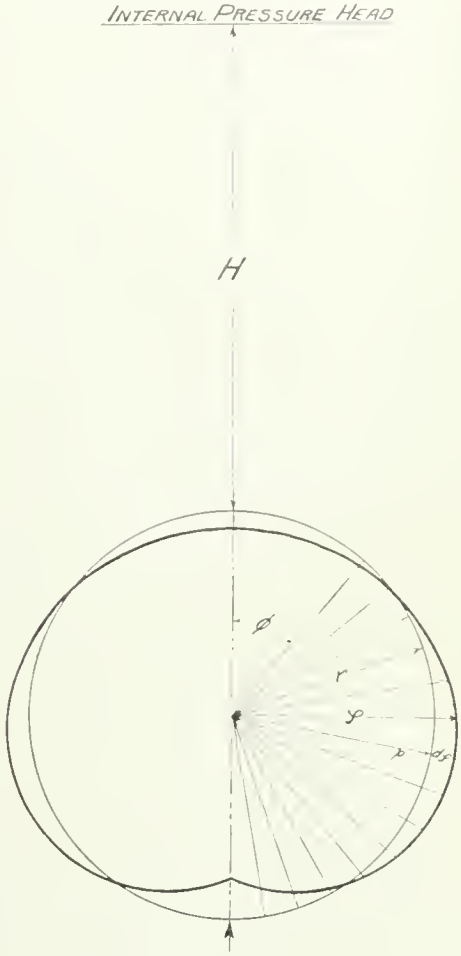
The bending moment at the crown due to a vertical load distributed over the horizontal section of the pipe as before and to a horizontal pressure uniformly distributed vertically against the pipe is equal to

$$M_B = \frac{1}{16}\left(1 - q\right) wd,$$

where w is the total vertical load on the ring, and q is the ratio of the horizontal to the vertical intensity of pressure.

The bending moments, it will be noted, are only given for the crown of the pipe. The reason for this will be clear on following the remainder of the discussion.

The reader is also referred to a paper by B. Haukelid in the June 14, 1913, issue of the ENGINEERING RECORD, on the "Stress Analysis of Circular Tubes." In this paper, Mr. Haukelid takes up the analytical and graphical determination of the stresses in circular tubes under various conditions of loading, and his analysis will be of assistance in connection with the results obtained in this article.



Theoretic Support.

Fig. 6.—Illustration of Equilibrium Curve.

A comparison of the formulae for the stresses due to internal water pressure, with the formulae for the stresses due to the weight of the shell, shows that they can be easily combined. It will be noted that angles from the vertical to the four nodes, or points of contra-flexure, are the same for both cases, and that the bending moments due to both causes are proportional at all points on the circle.

The analysis of the stresses in circular conduits due to internal water pressure has demonstrated the bending moments induced when such conduits are in a horizontal position. Where the diameter of the conduit, in an individual case, is large and the pressure head is comparatively low, these bending moments become very important,

so important that it is usually better to use a shape more nearly conforming to the equilibrium polygon. Mr. R. D. Johnson, in a paper before the American Society of Mechanical Engineers, printed in the May, 1910, Journal of the Society, on "The Hydrostatic Chord," presents very clearly the reasons against the use of the circular shape for such conditions. In this paper he also describes the hydrostatic chord, a curve which is eminently satisfactory for use under the conditions.

The hydrostatic chord is the curve which results when a flexible inextensible substance is loaded by fluid pressure which varies according to the head or depth of water at any point. For purposes of illustration, let us assume we have a large soft hose. If this is laid on a horizontal surface, it immediately flattens out. When it is filled with water gradually, it rounds out, but

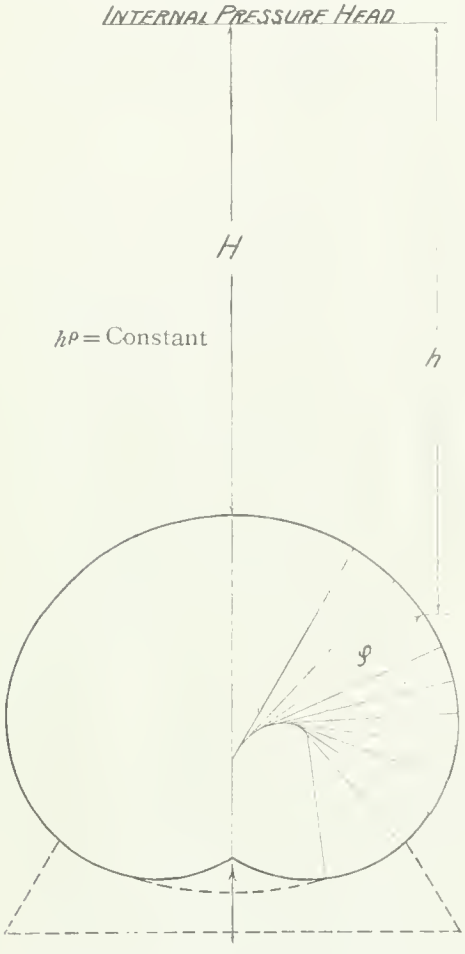


Fig. 7.—Illustration of Hydrostatic Chord.

with a flattened oblate form. As the pressure is increased it becomes more nearly a circle. As this flexible material cannot take any forces due to bending, it is easy to see that the shell is in a condition of pure tension, that this tension is equal throughout, and of finite value. If, on the other hand, this hose were hung in a vertical position and filled with water, it immediately takes the shape of a circle, as the pressure at any horizontal plane is uniform at all points on the shell.

The hydrostatic chord is the same as the hydrostatic arch with the stresses all reversed. The only investigation of this arch the writer has seen is that found in Rankine's "Applied Mechanics."

Since the tension in the hydrostatic chord is constant at all points in the shell, and this tension is measured by the product of the radius of curvature, and the head at that point, it is an easy matter to construct the shape for any desired condition. The equation of the curve will be $h\rho$ = a constant, where h is the head to any point on the curve, and ρ the radius of curvature at that point.

With the practical elimination of the bending moments in large conduits by the use of this shape, a very considerable saving in the material of the shell will result, and its use under certain conditions is almost a necessity.

The conditions to be met with in the design of large conduits under relatively low-water pressures, are: water pressure, back fill, and the constant weight of the shell. The water pressure will in all probability vary between certain defined limits, also the back fill. By choosing an equilibrium shape midway between the shapes for the limits of the water pressure, the stresses due to the various loads may be reduced to a minimum, and the material of the shell thus will be greatly lessened.

Reverting to Figure 5, the equilibrium polygon for a circular pipe under water pressure, the method of obtaining this polygon shows that any number of these curves may be plotted, as different values of H may be taken, and it is clear that these polygons will all pass through the same node points.

The question may arise in the reader's mind whether the equilibrium polygons shown in Fig. 5 and Fig. 6, and the hydrostatic chord shown in Fig. 7 are not identical for the same head and radius. They are not identical because the water pressures on the hydrostatic curve are normal to the curve itself, while the water pressures used in obtaining the equilibrium polygon are normal to the circle. There is very little difference, however, between the curves, for the conditions under which these shapes would be used in actual practice.

The assumptions, made in the early part of this paper, on which the mathematical analyses of the stresses were developed, were that the pipe was supported on a knife edge, and that the shell of the pipe was a thin ring of homogeneous material, having a constant modulus of elasticity. These conditions are not strictly true for pipes made of cast iron, steel, concrete or reinforced concrete, with regard to the later assumptions; but there will be little error in practical design. In practice, the conduit will probably be laid on a continuous bed or saddle of concrete, and in this case, the bending moments in the shell will be materially reduced. Investigation will usually show that the maximum moment, in the case of a conduit supported on a continuous saddle, is at the top of the pipe, and therefore the strength need be considered only at that point, if the shell is of uniform thickness and uniform material.

If in the judgment of the designer, the size of the conduit, and the water pressures to which it is subjected, are such as to justify the use of the hydrostatic chord for the intermediate pressure head; the bending moment induced in the shell for any head may be computed at any point, by noting the intercept between the equilibrium curves for the intermediate pressure head and the head under consideration. The bending moment will then be equal to the tension at that point multiplied by this intercept.

The tension for any point is obtained from the formula previously derived, viz.,

$$T = \gamma r \left\{ H + r\,(1 + k), \right\}$$

and the value thus obtained for the particular point under investigation is multiplied by the intercept.

The total stress is obtained by combining algebraically the bending stresses due to the weight of the shell, the back fill, and the weight of water, and adding to this amount the tensile stress due to the water pressure.

SOME PHASES OF THE CHANNEL TUNNEL CONTROVERSY.

THE question of a tunnel under the English Channel was referred to in *The Canadian Engineer*, Sept. 11th issue. At the Franco-British Travel Congress, held in London Sept. 23rd, the enterprise was given thorough discussion. The tunnel, viewed as an engineering problem, was dealt with by Sir Francis Fox, whose remarks were, in part, as follows:—

"The grey chalk through which the tunnels would be bored is 87 ft. thick at Dover and 70 ft. thick at Sangatte. It possesses the peculiar property of gradually 'puddling' itself and becoming impervious. Containing no flints, it is, as far as can be ascertained, free from fissures and slides; but should a fissure be encountered, it may be easily and satisfactorily dealt with by means of the system of high-pressure grouting which has been introduced within the last five or six years. A drainage heading would be driven from each side of the Channel, rising towards the centre, and connected at Dover and Sangatte with shafts for pumping and winding.

"The main tunnels would consist of two single-track circular tunnels, each of 18 ft. net internal diameter, and thus large enough to accommodate the rolling stock of the British and French lines, except only their locomotives, for which would be substituted electrical locomotives of ample power to deal with the heaviest trains running upon the main lines. Including the junctions with the main lines of railway in England and France, the total length of each tunnel would be 31 miles, the actual length under water being 24 miles. The tunnels would be placed 36 ft. apart, and lined throughout by cast-iron segments, of ample strength to resist any possible pressure, and grouted on the outside so as to secure a covering of cement which would not only prevent leakage into the tunnels, but also preserve the plates from corrosion. Assuming that 17 yards per day could be maintained for six days per week, the annual progress would be about three miles at each face, so that the driving of the drainage heading would occupy four years.

"Ventilation of the tunnels would be established by blowing air in the direction in which each train was travelling. The traffic being electrically operated, the volume of air required is very largely reduced. To keep the tunnels pure and fresh it would be necessary to supply 45,000 cubic feet per minute on each line of way, travelling at a velocity of 6 ft. per second, which was equivalent to a very light breeze. The prevention of fire in the trains is also one to which much attention has been devoted. In the case of specially built rolling stock for the London and Paris and other expresses no inflammable material should be used, and as the motors of the electric locomotive would be 'armored' against fire in case of short circuiting no danger would arise as regards the electrical working even from the employment of ordinary rolling stock. Assuming, however, that in spite of precautions any stoppage should occur in the tunnels, the passengers would readily pass along the tunnels in the rear of the train, where ample space would be available, as a footpath, clear of the electrical conductors. The tunnels would be lighted throughout by electricity. A separate and special circuit would be provided, so that in the event of the main traction current failing the lights in the tunnels would not be extinguished. Plans and sections for the proposed approach railways on the British side provide sorting sidings and a station near Maxton, just within the borough of Dover. These railways are well laid out to accommodate the traffic, and, in conjunction with the station where the exchange of steam for electric locomotives and all necessary sorting of traffic would take place, would provide full and complete means of communication with both the existing main lines between Dover, London, and the rest of England."

Dealing with the protection of the tunnel in time of war, Sir Francis Fox said there would be no question of the destruction of the tunnel. There was a dip at the Dover end. All that would be necessary would be to open a valve and let in a certain quantity of water. Then nothing could pass through, and the water could not be got out before the declaration of peace.

While dealing with this subject, it is interesting to call to mind some of the other schemes that have been advanced. Those of Henry Fairburn, in 1833, were decidedly clever. The main idea was to take down a considerable portion of the cliff between Dover and Folkestone and fill up the sea for an area of several miles with the material thus obtained. A huge harbor was to be formed at the extremity of the new piece of land, and similar works were to be undertaken at a corresponding point on the French coast. The two harbors were then to be connected by an enormous causeway, about ten miles in length. Further suggestions were that after the harbors had been made and protected by huge sea-walls, communication was to be continued by the construction of a chain bridge, a tunnel, a floating bridge, a bridge of ships, or a great steam ferry. Details of these and many other novel schemes, including one for a marine railway to carry ships across the Isthmus of Suez, occupy some 250 pages of a now rare treatise.

In 1856 Mr. Charles Boyd published his plans for a "Marine Viaduct or Continental Railway Bridge" between Dover cliffs and Cape Gris-nez, at a proper altitude for the safe passage of ships of the largest dimensions. The bridge was to be supported by towers rising from the bed of the Channel. The towers themselves, about 500 feet apart, were to have fog-gongs and lighthouses.

Perhaps the most ingenious scheme was that humorously propounded by the late Angus B. Reach in 1847. This was to take the form of a line of rails on a timber foundation carried by a bridge of boats, "the rails to work on hinges on board each boat, so as to yield freely to the action of the sea." Trains were shown in a sketch running up and down the inclines formed by the trough of the sea. A further joke by the same author was a Channel Balloon Line, in which a train was shown on an aerial platform supported by three balloons.

All these schemes are but marks of the general thought and effort to solve the problem of communication between England and the Continent, which, in spite of the great progress made in maritime navigation, has remained difficult on account of the obstacle of the channel, an obstacle of comparatively recent origin, the result of an erosion produced in a soil which was once continuous.

The study of the channel tunnel has brought to light one interesting fact, and that is the proportion of travellers between England, on the one hand, and France, Belgium, Holland and Germany, on the other, is slightly less than one per cent. of the united populations of these countries. But between France and Germany the proportion is two per cent.; and between France, Belgium, and Holland, eight per cent. M. A. Sartiaux, chief engineer of the French Northern Railway, and an administrator of a French society for the building of a channel

tunnel which was constituted in 1875, and which still exists, commented recently upon these proportions in travelling communication thus: "The proportion is remarkably low between England and the Continent, and we should have reason to be astonished at this if we did not know how much the changing of carriages, etc., complicates a voyage, and if we did not know the repugnance of many people to the smallest voyage on the sea.

"On the Continent, and even in England, there are business men who, although lacking nothing in activity, give way before the loss of time and the fatigues of the double crossing. It is necessary, whether going or coming, to resign oneself either to passing a night without sleep or sacrificing a day or half-day. Either of these alternatives is not encouraging. When, in addition, one is a victim to mal-demer, the voyage becomes really formidable. It is easy to understand, then, why many business men only undertake it on rare occasions, and why many tourists hesitate, with all the more reason, to undertake it when their sole pursuit is that of pleasure. . . . With the tunnel the journey between London and Paris would be five to five and a half hours by the most rapid route. But it would do more than take two hours off the present time necessary. It would make it possible, and here is the essential progress, to leave one of the capitals towards eight or nine in the morning, to be in the other at one or two o'clock in the afternoon, to leave it at six or seven in the evening, and to be back home again between eleven o'clock and midnight. Thanks to such a service, the movement of travellers between London and Paris would be doubled, perhaps trebled, at the end of a few years, and the current of business affairs between the two countries would follow a similar progression." M. Sartiaux then goes on to show how the growth of commerce between France and England is very much inferior to the growth between France and other Continental countries. The growth of general commerce between France and England for the years 1904 to 1911 was, on an average, 4.2 per cent. annually. But in the same period the commerce between France and Germany increased by 8½ per cent. annually, climbing up in that time from 1,117 millions of francs to 2,035 millions. "These figures have their eloquence. They show clearly the influence that is exerted by easy communication on commercial development."

Early Tunnel Schemes.—From figures, M. Sartiaux passes on to a short history of the various projects that have been made for the construction of a Channel tunnel, and it is interesting to note that such ideas have always originated on the other side of that important strip of water. As early as 1802 a French engineer named Mathieu had the idea of making a tunnel for a service of diligences, but he could certainly never have carried out his idea. A little later there was an idea, more weird than useful, for laying on the bed of the ocean an enormous iron tube. But it was not until 1867 that there was a serious proposal, based on geological studies of the bed of the Channel. This was made by Thomé de Gamond, and his careful borings in the Channel bed have been of great use to engineers interested since in the project. "In order to complete his scientific efforts Thomé de Gamond formed, in 1869, a Franco-British committee, whose aim was to work on both sides of the Channel towards a concession for the construction of the line. And here was commenced the diplomatic phase of the project, about which negotiations were opened between London and Paris. Far from opposing the idea, the British Government received the first communications favorably, and the reply that our Ambassador then received enabled pourparlers to go on with the greatest hopes of arriving at an entente. The conversation was, in fact, pursued between successive governments, and ended in 1874 in so complete an understanding that a Franco-British commission was formed to fix the conditions in a protocol, which was signed on May 30, 1876."

From then work went forward on both sides, although the most important was done by the French at Sangatte—the spot, by the way, from which Latham made his attempts to fly the Channel. There a long shaft was sunk and a gallery run under the sea to a length of over a mile. The works at Sangatte have never been abandoned definitely, and work could be restarted there again tomorrow if necessary. At Folkestone also a preliminary gallery was made. But work on both sides was stopped by an agitation which arose in England, the end of it being that no more was heard of the Channel tunnel scheme for many years; then, as now, the great objection being the possibility of military invasion.

CEMENT MANUFACTURE IN CANADA.

Concerning the manufacture of cement in Canada, Mr. J. McLeish, of the Division of Mineral Resources and Statistics, has issued the following data in his report on Economic Minerals and Mining Industries:—"Materials used in the manufacture of cement in Canada include marls, limestones, clays and blast furnace slag. The occurrence of cement materials is so widespread and abundant in all parts of the country that the question of their utilization is largely economic, being dependent upon the market for the product, the comparative availibility of suitable raw materials in different localities, the cost of fuel, and the transportation facilities. There are at present 24 completed cement plants in Canada, with a total daily capacity of about 28,800 barrels, besides several plants in course of construction. The total production in 1912 was 7,132,732 barrels, valued at $9,106,556, and in addition, 1,434,413 barrels were imported. The operating plants are distributed as follows:—One at Sydney, Nova Scotia, using blast furnace slag, three in the province of Quebec, two of which are near Montreal, and one near Hull, adjacent to the city of Ottawa, each using local limestone and clay. In the province of Ontario there are 15 plants with a total daily capacity of nearly 16,000 barrels. Of these 11 use marl and four limestone. The marl plants are located at Marlbank, Durham, Owen Sound, Lakefield, Hanover, Blue Lake, Raven Lake, Orangeville and Ottawa. The limestone plants are located at Belleville and Port Colborne. Formerly considerable quantities of 'Natural Rock' cement were made from a suitable calcareous limestone found in the Niagara peninsula, but this has now been entirely superseded in Ontario by the production of Portland cement. In the province of Manitoba, a 'Natural Portland' cement is made at Babcock, south-west of Winnipeg. Alberta has three limestone plants, located respectively at Calgary, Exshaw and Blairmore. A second limestone plant is being constructed at Blairmore, while a marl plant is being constructed near Marlboro about 145 miles west of Edmonton. British Columbia has one rock plant at Tod Inlet, near Victoria, and a second under construction at the same place, while another rock plant is nearing completion at Princeton."

The dock department of New York has decided upon building a drydock big enough to accommodate the "forthcoming 1,000-foot ship." The project will cost about $2,500,000.

VALUE OF THE FIXED CARBON TEST

By H. B. PULLAR,
Pullar & Enzenroth, Engineering Chemists, Detroit, Mich.

NOTE: On account of a bitter discussion regarding the propriety of limiting the maximum amount of fixed carbon, the City of Toronto was delayed six months in awarding its contract for supply of asphalt for 1913. The city bought in the open market during the first half of the year, as the Works Department did not seem able to convince the Board of Control that fixed carbon should be limited to 15%. Some of the controllers thought the specification unfair. Moreover, many chemists, paving contractors and city engineers differed in their opinions as to whether the specification was fair or unfair.

The city engineers of Canada will, within the next two or three months, write their specifications for asphalt supply. THE CANADIAN ENGINEER believes that a discussion of the desirability or undesirability of the "Fixed Carbon Test" would therefore be particularly valuable at this time.

During the next couple of months THE CANADIAN ENGINEER hopes to publish a number of articles from prominent chemists expressing their opinions regarding Fixed Carbon; and letters from city engineers and others who may have well-defined views on this subject are invited. Of seven well-known chemists whose opinions have been obtained by THE CANADIAN ENGINEER, two strongly favored limiting fixed carbon to 15%, four favored disregarding the test entirely, while one—Mr. Pullar—suggested a classification of asphalts with a different limit for fixed carbon for each class.

Mr. Pullar's suggestion is novel and has many points in its favor. In the following article he explains his claim that the maximum limit of fixed carbon for a gilsonite asphalt—for example—must be much lower than the limit of fixed carbon for, say, a Texas asphalt, in order that the gilsonite asphalt be in every way as good a paving material as the Texas asphalt.—EDITOR.

THE question of the value of the fixed carbon test as applied to bituminous materials and the advisability of eliminating this test from specifications, has been the topic of much discussion during recent years, and especially has this been true since the advent of certain asphalts which are good paving materials, even though they may have a high percentage of fixed carbon. Authorities disagree widely as to the value of this test, some advocating its total elimination from specifications, while others advocate a more strict observance of it. The writer, while agreeing with many of the objections to this test, believes that it is too important to totally eliminate from specifications, and when properly used is of the utmost value in helping to determine the quality of a bituminous material.

A particular objection to the fixed carbon test is, of course, the fact that different laboratories use different methods for running it. Such things as different sizes and different kinds of burners, different gas pressures, different crucibles and other details, make the results unreliable. Even in view of these possible varying conditions which might take place, the fixed carbon test is no more "liable to error" than a number of other tests which are applied to bituminous materials, and the elimination of the test for this reason should not be seriously considered.

The ductility test, which has been so strongly advocated by a number of authorities, has never reached the stage of perfection where any one chemist can exactly agree with the results obtained by other chemists. There are a number of ductility machines on the market, all of which are based upon the same principles, but which vary in detail, and which may cause varying results. Some are run by hand, some by motor, and the ductility as taken by different chemists on the same sample has varied as much as 20 cms. on a material having a ductility of less than 90 cms. This apparent inconsistency in tests is not only true of the ductility test, but of other tests which are used for determining the quality of bituminous materials. There is a personal equation in nearly all tests but their value is not eliminated, because of the fact that there is a personal equation and because chemists in different sections of the country cannot accurately check with each other.

The statement made in a recent publication regarding the fixed carbon test in which the writer states "The insertion of this test in any city, county, state or other specifications is purposely or unconsciously done, or caused to be done, by copying or otherwise from one or more persons or agents, who thereby seek to include some and exclude other brands of asphalts and road materials which compete and are perfectly good for use," is both unfair and unjust to a large number of engineers and chemists who believe in this test and who, from practical experience, know that this test, properly applied, is of value.

In order to show that this fixed carbon test is of considerable value and importance, a few results obtained on different samples and a discussion of the samples may prove interesting. A sample of asphalt made from Ohio oil, obtained in 1894, showed a fixed carbon of over 26%, while a sample of asphalt made from Ohio oil from the same field during the past year and which was treated by the same method, showed a fixed carbon of only 4.61%. While it is true this last product was not treated to the same extent as the first one, yet had it been treated to a greater extent it would have under no circumstance given over 10% of fixed carbon. This is proved by the fact that Ohio oil obtained in 1907 and mixed with a high per cent. of gilsonite, only showed a fixed carbon of 9.46%. The high fixed carbon in the first sample mentioned can, without question, be attributed to the fact

that in 1894 residuum oil was carelessly produced and a considerable amount of cracking occurred during the process of distillation. The asphalt produced from this oil was very poor in quality and proved a failure when used for paving purposes. There is no other test which so clearly and decisively showed the poor quality of this asphalt as that of fixed carbon.

In 1910 the value of the fixed carbon test was very clearly brought to the writer's attention. Two samples of asphalt obtained by the treatment of residuum oil (the oil being taken from the same district but produced by different refineries) showed a fixed carbon of 9.88% and 12.32% respectively. The quality of the asphalt showing the fixed carbon of 12.32% was very poor and not suitable for bituminous work, while the sample which showed a fixed carbon of 9.88% was good quality and equal to the standard for that class of material. Upon investigation it was found that the oil from which the poor sample was made was a mixture of poor, heavy-grade residuum oil which had been badly cracked during distillation and a lighter gravity residuum oil. There was no other test which so decisively showed the true value of these different materials (which all belonged to the same general class of asphalts) as that of fixed carbon. For the class of product to which this asphalt belonged, a limit of not over 11% of fixed carbon would always fully protect a city against any poor quality of oil. Likewise another bituminous material obtained by the same method, but from oil from a different field, showed a fixed carbon varying from 10 to 14%. Those asphalts which showed the high per cent. of fixed carbon did not prove a success; seemed "dead," and after a few months showed a separation and exudation of oil. They were poor quality and were not suitable for bituminous work. The fixed carbon test more clearly indicated this than any other test known.

The asphalts which have been mentioned above, have all been produced by the treatment of residuum oil with air. However, the value of the fixed carbon test not only applies to this class of asphalts but also to other asphalts produced from different oils and by different methods.

One of the well-known brands of California asphalts which was active on the market a few years ago, showed a fixed carbon of 18.06%. This asphalt was produced by distillation and treatment with air at high temperatures, which resulted in a "cracked" product of poor quality. It is to-day almost unknown, and is not considered by authorities to be a suitable material for road and paving purposes.

Another sample of California asphalt which proved a failure and which was carelessly prepared, showed a fixed carbon of 16.29%, and still another which was a failure showed a fixed carbon of 15.43%. The California asphalts which have given the most successful results, which are produced by the largest and most reliable companies, and which are recommended as standard material by leading engineers throughout the country, vary in their per cent. of fixed carbon from 11 to 14%. There has during the past year, however, appeared upon the market a new brand of California asphalt which seems to be of good quality and which ought to give successful results—the average fixed carbon for this particular brand being 9½%.

It appears from the foregoing facts that the fixed carbon test is therefore a very important test, if not the most important one for determining the quality of the California asphalts. Certain authorities believe that this cracking can be better shown by the solubility in carbon tetrachloride, but the writer has found that the carbon tetrachloride test requires more attention to details and greater care. At the same time it is more "liable to error" than the test for fixed carbon, and also it is more difficult to obtain from it satisfactory results and definite conclusions.

The fixed carbon test is of considerable importance when testing the so-called natural asphalts after they have been fluxed with residuum oil. A poor quality of oil will show up by high fixed carbon; and if properly applied and careful records are kept, this test will probably indicate as much as any other the amount of oil which is being used to flux the "native asphalts."

The probable reason for the recent interest aroused in the fixed carbon test is the advent of the Mexican asphalts. Owing to the peculiar characteristics of the oil obtained from Mexico and the asphalt product resulting from the distillation of this oil, a much higher fixed carbon is properly obtained than would naturally be supposed, averaging between 14% and 18% for the well-known brands. As a maximum of 15% is incorporated in several specifications throughout Canada, therefore making it difficult for the Mexican asphalts always to comply with them, it is only natural that this question be given considerable attention. From other tests and from the practical results which have been obtained, it is apparent that asphalts carefully prepared from the Mexican oils will give satisfactory results, despite comparatively high fixed carbon, and that for this class of materials a higher per cent. of fixed carbon could reasonably be allowed. However, the writer is very much of the opinion that it would be unwise to entirely eliminate this test or not state a definite limit, for, without question, Mexican oils can be as easily cracked as other oils, and the resulting products obtained from cracked Mexican oil will not be of good quality any more than that obtained from cracked oils from other fields. As the fixed carbon test is one of the best indicators for cracked oil, it is of the utmost importance that this test be very carefully considered.

From the foregoing statements it is apparent that there are many different conditions under which the fixed carbon test may prove of value. The writer does not advocate the arbitrary setting of the same per cent. limit on all bituminous materials, nor does he by any means advocate the elimination of this test, but he advocates a more systematic and proper use of it. At the present time a large majority of specifications are drawn up in order to admit a number of asphalts in competition. They are usually so open to the various asphalts which are admitted under them that the producing companies may practically ignore their requirements, and so far as keeping any particular material uniform and of the highest quality, they are of little value. For this kind of a specification a fixed carbon limit of 15% or any per cent. is useless and unjust.

In order to eliminate all undesirable features it would be advisable to draw up specifications dividing the bituminous materials into various classes and to draw strict requirements for each class.

By doing this the fixed carbon, as well as a number of other tests, would prove of very material value. Chemists could then use the fixed carbon test, not only as a help to identification, but as an important test in deciding the qualities of the material under examination.

CONCRETE ROADS.*

By Hon. Frank F. Rogers,
State Highway Commissioner of Michigan.

MUCH of value has been written in the past two years on concrete roads and pavements, but a great deal is in the nature of theoretical discussions quite largely based on laboratory experiments, hence when an opportunity is offered to make a field study of many miles of concrete roads, some of which have seen four years of service, it should not be lost.

The writer makes no claim to being a concrete expert but simply has been fortunate in having the opportunity to study at first hand, and in some detail, the behavior of a large mileage of concrete roadways in Wayne county, Michigan. This county, without doubt, has a larger mileage of concrete roadways than any other county in the United States, or than is possessed by any equivalent area under a single local government in any foreign country. There are now completed in Wayne county about 65 miles of concrete highways outside the corporate limits of cities and villages.

For the reasons above stated the writer desired to spend the time allotted to him in a somewhat detailed study of the local concrete roads which most of you will visit before leaving the city rather than to treat the subject in a more general way. All of the main highways leading out of this city have been concreted to the outermost boundaries of Wayne county and several cross-roads have already been concreted. The principal roads are the extensions of Woodward, Grand River, Gratiot and Michigan avenues, while River Road and the extension of Fort Street running southerly are concrete roadways that should not be overlooked.

The State Highway Department, with the co-operation of the road officials of Wayne county, and assisted by Prof. John J. Cox, instructor in highway engineering at the University of Michigan, has just taken up some detailed and rather minute observations of these roads which will extend over a period of years in the hope that after a while a safe estimate can be made of the probable life and cost of maintenance of such pavements as the county is now building, and under such traffic, soil and climatic conditions as prevail in this locality.

The first work in this study will be careful traffic records covering enough time and at such frequent intervals as will give a reliable estimate of the average daily traffic for one year. The first records were taken for one continuous week beginning August 21, and a part of this record, which is given in the accompanying table, will be used for the purpose of the present discussion.

The next step was to start a permanent record showing the present condition of each 25-foot section (the distance between expansion joints) of all the different roads. The observations for this record were made September 2nd, 3rd and 4th and cover 6,384 sections and a little over 30 miles of road. Several pieces of road have not been taken at this time. The oldest roads were built in 1909 and the newest that were taken were built in 1912, having been down one year.

For the purpose of this record the defects in the slabs or sections have been classified as longitudinal, transverse and diagonal cracks and holes. The records were taken in ordinary field books, the left hand column of the left hand page having been previously numbered with an automatic numbering stamp to designate the record number of each slab, while the four columns to the right were headed L—T—D—H, respectively, being the first letters of the words indicating the defects named. Opposite each number and in the proper column vertical, horizontal or diagonal marks were used for symbols to indicate the form of the crack, while small ovals were used to indicate such holes as seemed worthy of note. Tar had been spilled on many spots that were not defective.

The first mile of this road was built in May and June, and opened to traffic in July of 1909, thus giving it full four years of wear. The traffic record of this road shows a daily average of 2,160 vehicles, of which 88.1% were motor-driven.

The soil is clay loam, inclining a little more to sand at the northerly end. A double-track electric railway occupies the westerly side of the street. Between the railway and the concrete roadway is a very shallow gutter under which was laid a tile drain from 2 to 3 feet in depth. On the opposite side is an open ditch, the bottom of which is from 2 to 4 feet below the crown of the roadway.

The pavement is 18 feet wide, has a crown of 3″ and a blind curb 8″ wide and 4″ deep under the outer edges which were somewhat bevelled. The concrete was composed of Portland cement, crushed field stone or cobbles and sand mixed in the proportion of 1:2½:5 for the base, which was 4″ thick. The top layer was made of the same materials, using a 1:2:3 mix and was 2½″ thick.

No very definite data can be secured to determine the wear, which seems to be slightly greater on the side opposite the railway, but measuring from some of the harder pieces of the coarse aggregate which have been worn but little, if any, we have estimated the general wear at about ¼″, which would be an average of 1/16″ per year.

This mile was divided into sections of about 25 feet, separated by expansion joints, there being 209 sections to the mile. The most of the sections were separated by four thicknesses of tar paper separated by thin boards which it was planned to remove as the work progressed, though many of the boards are still in the pavement. Four of the joints were protected by pairs of steel angle bars, separated with tar paper and placed with one leg of each angle back to back so that the other leg of each bar was flush with the surface of the concrete, thus covering a space of about 4½″ at the joints. The concrete wears slowly on each side of the angles, leaving a raised joint that is slightly noticeable when driving over the pavement. This was an experiment which has not been repeated.

Of the 209 sections constituting the first mile on Woodward Avenue, 80 showed longitudinal cracks, 32 transverse cracks and 2 diagonal cracks, while 46 sections were recorded as having holes, making a total of 160 sections which are more or less imperfect, or 76.5 plus % of the entire mile.

The remaining portion of Woodward Avenue, 252 sections, was built in 1910 using the same materials and the same mix. No blind curb was used and the crown was reduced to 2″. The soil on this section is considerably more sandy, especially toward the north end.

On this portion of Woodward Avenue, 29 sections have longitudinal, 22 sections transverse, and 6 sections diagonal cracks. Eleven sections have holes, making a total of 68 defective sections or 27 plus % as compared with 76 plus % in the first mile.

*Read at American Road Congress, held at Detroit, Mich., Sept. 29 to Oct. 4, 1913.

On Gratiot Avenue, in the season of 1910, 9,000 feet of 16-ft. concrete roadway was built. On this pavement gravel and sand were used for the aggregate and a one-layer concrete having a 1:2:4 mix was laid. The soil is a clay loam and rather heavy. This road was not completed until late in the season and was opened to travel in November. It immediately pitted and looked rough and has been covered with a surface treatment of refined tar and fine gravel. It was re-covered this season, using a rather light grade of tar (Tarvia A) but is already shows some tendency to scale off. The experience in some other places leads the Commission to believe that a heavier grade of tar gives better results.

Beyond this portion of the roadway 326 sections of the same width concrete were laid in 1911, reaching the county line. Washed pebbles and sand were used for the aggregate in a 1:1½:3 mix, one course concrete 7″ deep being laid. The records for this piece are as follows: Longitudinal cracks, 11; transverse cracks, 10; diagonal cracks, 3; holes, 6; showing a total of only 30 defective slabs, or 9.2 plus %. The traffic count on this road, taken at the county line, shows 507 vehicles daily, 65.8% of which are motor-driven.

On the Grand River Road 61 sections of two-course concrete, the same as laid in the first mile of Woodward Avenue, were built in 1909. The soil is a clay loam. The records show 11 longitudinal cracks, 2 transverse cracks, 1 diagonal crack and 3 holes, a total of 17 defective slabs, or 27.9 minus %. The traffic count showed 1,064 vehicles, 56.5% of which were motor cars.

In 1910, 341 more sections were added to Grand River Avenue under contract, the specifications being the same as for the north end of Woodward Avenue. Thirty-three of these slabs became more or less pitted, some having quite large holes. They have been repaired by covering with refined tar and stone chips so that no defects could be observed at the time of the count, hence only 308 are shown in the table. The defects noted are as follows: 59 longitudinal, 20 transverse, 29 diagonal cracks and 46 holes, a total of 154 defective slabs or 50%.

In 1911, 515 additional sections of one-course concrete were placed on the Grand River Road. Washed pebbles and sand were used for the aggregate with a 1:1½:3 mix. The Baker steel joint was used in all of this work except the first six sections. The defects noted are as follows: Longitudinal cracks, 8; transverse, 26; diagonal, 3; and holes, 5; making a total of 42 defective sections, or 8.2 plus %.

In 1912, 1,208 more sections were added to Grand River Avenue, reaching to the line between Wayne and Oakland counties. The count on these sections shows as follows: 66 longitudinal cracks, 37 transverse cracks, 6 diagonal cracks and 5 holes, making a total of 114 defective sections, or 9.4 plus %. The soil grew more sandy as the road extended westerly, considerable stretches being almost free from clay or loam.

On Michigan Avenue 481 sections of concrete, 17 ft. 8 in. wide were laid, using washed pebbles and sand for the aggregate in a 1:2:4 mix. The soil for the most part is a sandy loam, but a little heavy. The count shows as follows: 219 longitudinal cracks, 48 transverse cracks, 23 diagonal cracks, 21 holes, making a total of 311 defective sections, or 64.6 plus %. The traffic count shows 1,009 vehicles, 67.5% of which were motor-driven.

In 1911, 1,570 sections were added to this piece of road, using washed pebbles and sand for the aggregate and a 1:1½:3 mix. The soil over which this pavement was laid is a sandy loam running into light sand at the west end. The count shows the following: 219 longitudinal cracks, 80 transverse cracks, 42 diagonal cracks, 14 holes, making a total of 355 defective sections, or 22.6 plus %. In 1912 this road was paved to within 1¼ miles of the county line, and this year completed to the county line, but no record was taken farther west than the east limits of the village of Wayne.

In 1910, 149 sections of concrete 15 ft. wide and 6½″ deep were laid on the River Road, using gravel and sand for the aggregate and a 1:2:4 mix. The soil over which this road runs is for the most part heavy clay. The count shows as follows: 49 longitudinal cracks, 5 transverse cracks, 6 diagonal cracks and 2 holes, making a total of 62 defective sections, or 41.6 plus %. The traffic count shows 538 vehicles daily, of which 78.9% were motor-driven.

In 1911, 434 sections were added to this road some distance below the village of Trenton. The pavement was 15 ft. wide, 7″ thick, built of washed pebbles and sand for the aggregate, using a 1:1½:3 mix. The count for this stretch of road shows as follows: 165 longitudinal cracks, 17 transverse cracks, 13 diagonal cracks and no holes, a total of 195 defective sections, or 44.9 plus %.

In 1912, the gap between this piece of road and the southerly limits of the village of Trenton was closed in with a similar pavement to that just described, comprising 213 sections. The count of this piece shows defects as follows: 14 longitudinal cracks, 8 transverse cracks, 4 diagonal cracks and no holes, making a total of 26 sections, or 12.2 plus %.

The same year there was added to the south end of the work done in 1911 something over two miles of concrete roadway, but of this only 208 sections were counted. Of the sections counted, 17 show longitudinal cracks, 9 transverse cracks, no diagonal cracks and no holes, a total of 21 defective sections or approximately 10%. The soil of the entire road was heavy clay.

In 1910, one-half mile of gravel concrete of a 1:2:4 mix, 12 ft. wide and 6½″ deep was built on Fort Street. This concrete, like that already referred to on Gratiot Avenue, was built rather late in the season, and was opened to traffic in November. It immediately pitted to such an extent that it has since been coated with refined tar and fine washed gravel, about ¼″ in size. This covering makes an excellent surface and wears fairly well. Of course it was impossible to observe any further defects in the concrete at this time. Continuing south, in 1912 450 sections of concrete 12 ft. wide, 7″ deep, and of 1:1½:3 mix were added. The count on this piece of road follows: Longitudinal cracks, none, although another observer has reported there are 2; transverse cracks, 19; diagonal cracks, 9; and holes, 1. Total defective sections, 29, or 6.5 minus %.

From the foregoing, it is strikingly apparent that the percentage of defects varied greatly in the different roads. A careful study of this variation in connection with the age of the pavement will soon convince one that mere age has not produced the defects noted. For example, 252 sections built on Woodward Avenue in 1910 show but 27% defective slabs, while 308 sections built on Grand River Avenue, the same year and under the same specifications, show 50% of defective slabs. There are two noticeable differences. Grand River Avenue was built by contract on a clay loam soil while the portion of Woodward Avenue named was built by day labor under the direct supervision of the engineers of the County Road Commission, on a soil more sandy and, presumably with a little better sub-drainage. Again, 481 sections built on

Michigan Avenue the same year with sand and pebbles for the aggregate and a 1:2:4 mix show 64.6% of defective slabs. This was on clay loam soil. We might also mention 149 sections built on the River Road in 1910 on heavy clay soil, under the specifications last named, which show but 41.6% of defective slabs.

The most noticeable feature concerning these defects is that the longitudinal cracks almost always appear in groups, seldom singly. This indicates that there must be some local conditions in the foundation, due to insufficient drainage, soil conditions, newly made fills or uncompacted sub-grades that cause these defects. Longitudinal cracks almost invariably appear on fills and on cuts, apparently with as much frequency in the latter as in the former. It would seem that cracks on the fills are due to the settlement of the embankment, and in the cuts the presence of water and frost in the sub-grade. Briefly, the writer's opinion is that these cracks are due, first, to the settlement of the newly made fills, and second, to water that has not been completely removed from the sub-grade, plus frost. If these causes could be thoroughly eliminated it would seem possible to build concrete roadways to the width of 15 or 16 feet, where sufficient expansion joints are used, without fear of trouble from longitudinal cracks.

It has been argued by the Morse-Warren Engineering Company, in a recent publication, that it is impossible to build concrete pavements (wider than 12 ft.) which will remain free from longitudinal cracks without using longitudinal joints, unless the pavement is so thick as to make the price practically prohibitive. The table accompanying this report, which shows 450 sections of 12-ft. roadway on the Fort Street road, would seem to bear out this assertion, but a mile of concrete on the Eureka Road, which the writer did not get time to inspect, shows a great number of longitudinal and transverse cracks in a 12-ft. concrete roadway, where the soil conditions are the same as on the Fort Street road referred to. The only apparent difference is that the former is a 1:2:4 mix and the latter a 1:1½:3 mix, washed pebbles and sand being used for the aggregate in both cases.

But long stretches of pavement, 16 ft. wide and now two years old, on Grand River and Michigan Avenues, which show no longitudinal cracks, would seem to prove that this statement is not necessarily true, and that a sufficient amount of money spent in compacting and draining the foundation or in reinforcing the concrete over newly made fills, would produce pavements free from the objectionable longitudinal crease, whether natural or artificial. Most persons are agreed that transverse cracks are almost always due to defective expansion joints. It has been thoroughly demonstrated, both theoretically and practically, that 25 feet is frequent enough for the expansion joints, and it is quite possible that they might be placed farther apart with safety—probably not less than three to 100 feet.

The diagonal cracks are doubtless due to causes which are a combination of those noted under longitudinal and transverse cracks. Many diagonal cracks were noted where the corners only were broken off, frequently on adjoining corners of adjacent slabs, indicating that the slabs were united through the expansion joints with a bond stronger than the tensile strength of the concrete on either side of the joint.

The holes noted are perhaps of less importance than the different kinds of cracks. In a few instances they are rather large, sometimes a square yard or more in area, but such places are very rare and most of the holes noted are due simply to some foreign substances getting into the concrete, like clay, wood or some fragment of an inferior rock that might chance to be a part of the aggregate. This was more noticeable where crushed cobbles were used for the coarse aggregate than where washed pebbles were used.

Any one familiar with the quality of rocks which constitute Michigan cobbles will understand that the principal objection to this material for an aggregate on concrete roads is the varying qualities of these rocks, ranging from soft to hard granite, quartzite and trap. A study of the roads where these materials have been used shows much more wear in the spots where the softer rocks happen to be at the surface.

Up to the present time the defects noted, except the pitted conditions of the concrete roads which have been re-surfaced in the manner already described, are not serious and are not causing any additional expense for up-keep. In the past two years the expansion joints on all the old work, whether reinforced or not, have been coated with refined tar and sand once a year. Thus far, the cost has ranged between $50 and $100 per mile, depending on the distance of the work from the base of supplies. These repairs are proving adequate and satisfactory, and while the defects noted are something of a reflection on the present method of building concrete roadways, they are really no reflection on the use of concrete as a suitable material for making hard and durable surfaces over our country highways wherever traffic conditions warrant, and the community has the ability to pay the cost of high-class road surfaces. There is no question as to the necessity of some form of very permanent roadway near the city of Detroit, neither is there any question as to the ability of Wayne county to pay for a roadway that is good enough and permanent enough to meet the requirements of its traffic. In the writer's opinion, Wayne county has made no mistake in choosing concrete as a paving material for its main roads.

DISCUSSION ON "CONCRETE ROADS."

By A. N. Johnson.*

It is evident that if one portion of a concrete road surface exhibits a special weakness it must be due to non-uniformity of the concrete. This will happen if soft pieces of material are in the aggregate. Many gravel banks contain enough soft pebbles to render the gravel useless for concrete-road work, though frequently these soft pebbles have somewhat the general appearance of the sound material and, unless a careful examination is made, will not be detected.

Another cause for local weakness in concrete is the non-uniform distribution of the mortar and the aggregate. It frequently happens, particularly with very wet mixtures, that the coarser aggregate will not be thoroughly distributed but will occasionally be separated into small collections or nests of the larger pieces, which contain a very small amount of mortar. There is no mixer that has come under the writer's observation which will mix and deposit a batch so uniformly that all portions will contain the proper amount of coarse aggregate and mortar. It is necessary, therefore, in the construction of a concrete road to have one or two men constantly at hand to correct such uneven distribution by shoveling out the

*State Highway Engineer, Illinois.

pockets of coarser aggregate to be found in the centre of nearly every batch that is deposited on the road and replacing these pockets with mortar, which usually runs to the bottom and edges of the batch.

The causes of the other three defects noted by Mr. Rogers (see Engineering Record, Oct. 11, 1913, page 409)—longitudinal cracks, transverse cracks and diagonal cracks—are perhaps more difficult to ascertain in a given instance. The data presented have been rearranged according to the age of the various pieces of road in the table following. In order to have a proper basis of comparison the number of cracks per mile has been computed for the roads built in 1909, 1910, 1911 and 1912 respectively.

At once one is struck with the increase in the number of cracks with each succeeding year. This increase is particularly marked during the first three years, but apparently falls off sharply during the fourth year.

A notable coincidence is that the curve showing the total number of cracks per mile of all kinds is approximately a straight line for the first three years, or, in other words, the increase in the number of cracks was approximately the same for each of these years.

There is also considerable agreement of the curves for the longitudinal, transverse and diagonal cracks during the first three years, but no such agreement for the fourth year. It is to be borne in mind, however, that for the fourth year data are given for only two pieces of road about 1.3 miles in length. However, as these pieces were laid with a leaner mixture than much of the other work and constitute the first concrete work done by the Wayne County Commissioners, all the evidence would point to the conclusion that this stretch of road would show at least as many defects as will appear later in the other roads.

The value of future observations to be made at intervals of not less than three months will be evident. These observations should note carefully all the cracks that are found, both as to their character and, particularly, as to their distribution, so that in the future the location of new cracks as they appear may be known, as well as the approximate time of the year when they occur.

It can be fairly assumed that the slabs of concrete are approximately of the same strength, offering practically the same resistance to all exterior forces to which they are subjected.

Among the forces which would cause the slabs to crack are variations in temperature, extraordinarily heavy traffic loads and unequal settlement of the foundations. It is more than probable that the cracks are due to no one of these causes alone, but rather to their accidental combination. If the changes in temperature were the prime cause, it could be expected that all slabs would show approximately the same number of cracks, for the reason that all portions of the road are subjected approximately to the same temperature variations. But an examination of the roads shows many slabs in continuous stretches which have not cracked at all, regardless of the age of the road. It can, therefore, be concluded that temperature changes alone are not sufficient to cause cracking of the slabs in general.

While extraordinarily heavy moving loads may not be so generally applied to all the slabs, and therefore not cause as uniform an appearance of cracks, yet if this be a principal cause it could be expected there would be a large number of contiguous cracked slabs. But there is practically no evidence to indicate that there have been loads heavy enough to cause the pavements to crack from this reason alone.

The third cause that has been mentioned—unequal settlement of the foundation—is one that would not be generally distributed; for while settlement might occur in one place, there very likely would be considerable distances where it did not occur. Moreover, it will be appreciated that the manifold conditions which would produce unequal settlement would cause an erratic occurrence of any results from this source. And the haphazard occurrence of the cracks would indicate that the cause is not general throughout the length of the roads. The writer is, therefore, of the opinion that the majority of the cracks are due primarily to unequal settlement of the foundation or subsoil beneath the broken slabs. It is quite possible that settlement by itself would perhaps not be sufficient to cause the slab to crack, but on the passage of heavy traffic or with the movement of the slab under temperature changes there would be added just enough extra stress to overcome the strength of the slab and produce the crack. If, therefore, it is possible to guard against unequal settlement of the foundation, one of the chief sources of cracks in the pavement will be overcome.

The writer has observed that the concrete slabs usually do not crack until after they have been in service about a year. The first cracks generally appear during the late spring and early summer following construction. An explanation is that during the winter and early spring the ground is well saturated with moisture and dries unevenly; the consequent settlement is, therefore, not uniform. Special precaution with the underdrainage should accordingly be taken to provide thorough and uniform draining.

The writer does not believe that it is necessary to place expansion joints as close together as 25 ft. On three pieces of work constructed under his supervision in 1912, totalling 2.3 miles, none of the sections was less than 50 ft. in length, many being 60 and 75 ft., and one or two as long as 100 ft. The number of cracks per mile in these roads at present is: Transverse cracks, 9.1; longitudinal cracks, 9.1, or 18.2 cracks per mile. The total number of cracks in the 1912 work on the Wayne county roads, using 25-ft. sections, is 19.1. It will be necessary to have much more data before it can be definitely concluded as to how frequent the joints should be; but from the observations that have been made it seems that the joints may be made further apart than 50 ft. rather than nearer together.

Lest a wrong impression should be gained from the emphasis laid upon the defects found in the Wayne county roads, the writer would state that from a number of personal inspections he feels that the Wayne County Commissioners have amply justified their adoption of this form of construction.

A NEW TYPE OF ENGINE.

A new type of rotary engine has been invented by a Birmingham firm. A model is being shown in London, where it is described as "England's answer to her critics—an engine that is far and away better than even the Gnome." It is claimed that the engine, which is driven by petrol, is almost vibrationless, while its weight is only 2½ pounds per horse-power. It has no fly-wheel, no crank-case and no cam-shaft. The new engine is expected to have far-reaching effects on the motor car, the motor boat and the aeroplane.

SANITARY SURVEYS OF RIVERS.*

By J. R. Malek, C.E.,
Assistant Provincial Sanitary Engineer, Regina.

IN dealing with the subject of this paper, the writer wishes to state that the object in view is to make a few general remarks on the necessity of carrying out sanitary surveys of rivers and the general lines employed in carrying out such work, but does not propose to deal with sewerage purification works or water filtration plants situated on the banks of rivers and streams in this or other countries.

Object.—Sanitary surveys have all been carried out chiefly with a view to ascertaining the state of the streams which have been subject to contamination, either by the discharge of crude sewage of adjacent towns into the river or else by the general refuse of communities along their banks or through industrial wastes and the waste water from mines or quarries or other works too numerous to mention.

It need hardly be mentioned here that the duration of the work and the observations to be taken, may extend over any period from a few days, weeks or months to possibly one or two years, according to the ultimate object in view or to the size and varied conditions to be met with in the various rivers or waters under observation.

Results of Pollution.—Unfortunately, it is only too true that as civilization has advanced and the number of factories and towns have become the centres of manufacturing industries, that the tendency has been in the past to use these courses in their near vicinity as an easy and inexpensive means of getting rid of the ever-increasing filth and rubbish to be expected to collect from such centres, with never a thought bestowed on the trouble and future sickness in the shape of epidemics of typhoid, dysentry, cholera and diphtheria, not only to themselves, but to the towns and villages lower down on the same stream, which may be their nearest water supply, but to the farmers and dairymen whose animals water themselves in the river or at the pools left on the shoals.

The older countries have long ago realized the necessity of investigating the serious condition of their waterways, and extensive sanitary surveys have been carried out by some of their most eminent scientists, engineers and surveyors, with a view to ascertaining the extent of the contamination, which "Findings" are submitted in the shape of reports to the governments concerned.

The United States and Canada, both comparatively new countries, are likewise realizing the dangers likely to arise from the present state of pollution of their streams, rivers and great lakes.

In the States, two recent surveys will, no doubt, be fresh in the minds of those present (a) the thorough and exhaustive sanitary survey of the "Potomac River" by Asst. Surgeon J. Goldberger, the full report of which is given in the "Report on the Origin and Prevalence of Typhoid Fever in the District of Columbia," which was brought out in 1907 in the form of a report by the United States Government, (b) the very recent extracts on the report by Messrs. Forbes and Richardson, of the sanitary survey of the "Illinois River," in connection with the pollution caused by the sewage discharge from the Chicago Drainage Canal.

The Canadian Engineer, of July the 13th, 1912, published extracts from the report by Mr. James Meadows, sanitary engineer to the Board of Health at Quebec, on the survey of the Ottawa River, carried out by him.

The object of this survey was to arrive at the difference in the state of the river in 1910, compared to the condition when Dr. Wyatt Johnstone made his in 1891, when the population for Ottawa and Hull combined was only half what it was in 1910.

Dr. W. Johnstone, in July, 1891, found that samples taken at a point five miles below Ottawa, had 500 bacteria per cubic centimeter, the next highest return was at Thurso, a town thirty miles below Ottawa, when it was 201 bacteria per c.c., from this point they gradually diminished.

In September, of the same year, his next survey was carried out at a point 25 miles below Ottawa, the samples taken showed the number to be 1,530 bacteria per c.c. at a point 65 miles below the capital, they had diminished to 48 per c.c.

The survey carried out by Mr. Meadows in 1910 shows in nine years a very great increase of pollution in the river, owing to the increase of population and the discharge of sewage and factory wastes that was taking place.

At Pembroke, the samples taken gave 110 bacteria per c.c., at 113 miles lower down and seven miles below Ottawa, they showed 700 bacteria per c.c. The next highest reading was 1,000 per c.c. at a distance of 179 miles, after which it decreased rapidly.

In the October survey of 1910, when the water was at its lowest level, the samples taken showed that at Pembroke there were 43 bacteria per c.c., at Ottawa, 106 miles lower down, the samples had 100 per c.c., at 113 miles, or seven miles below Ottawa, 1,600 per c.c. The highest taken was at a point 133 miles away when the samples taken showed 1,900 per c.c. It there dropped to 1,450 per c.c., at a distance of 179 miles from Pembroke.

The above is given to show how severely even such a large river as the Ottawa may suffer through continued pollution taking place and the great value a sanitary survey is, in enabling the authorities to get a clear understanding as to its conditions.

Professor Heider, in 1893, in his extensive and prolonged sanitary survey of the River Danube, into which Vienna discharged its sewage, found that it was carried along the right bank of the stream, preserving its own bacterial characteristics and not mixing perfectly with the water of the river for a distance of more that 24 miles. Where sudden dips take place in the river bed it has been found that these act like sewage tanks accumulating sludge.

In a recent river survey carried out by the writer for a civil action in which the discharge of crude sewage by a small town was causing considerable damage to property lower down along the side of the stream for which the owner clained damages, the sewer pipes had been placed in a diagonal line across the river, thereby forming a kind of groyne, throwing the current on to the opposite bank, which, owing to the gravel shoal that had been formed, set up a back current on to the plaintiff's land, causing lighter solids to settle along the bank and seriously damaging his property.

At a distance of 20 yards from the mouth of the pipe, the bed of the river shelved down and for some distance formed a saucer like hollow. It was noted when the river got to summer or normal levels, that the ordinary current had little or no effect on the deposits lying at the bottom and even with a "freshet," which increased the depth of the water by an additional five feet, it made no appreciable difference. It was found after careful examination

*Read before the Third Congress of the Canadian Public Health Association, Regina, Sask.

that only after a rise of 8 feet above the normal, a portion of this matter got away, and that in the ordinary way the rapid shelving of the river's bed caused the current to pass over it, whilst the surface water was considerably disturbed, the portion beneath was not in the least affected until a heavier "freshet" came down and scoured out.

Dominion Health Commission.—It is with considerable satisfaction that we see that the Dominion Government has recently formed a Health Commission of 18 members to look into and report on the health of the cities and towns upon the banks of our rivers and streams in this country when it is to be hoped that they will frame such laws and regulations as will prohibit the discharge of untreated sewage and trade wastes, as well as other impure matters, which are liable to injure the health of the community at large, into the waterways, which should be looked upon not as ready-made sewers, but as valuable national assets.

Surveys.—To get a general and fair estimate of what is taking place will of a necessity demand not only an inspection to be made during the open seasons or summer months, but also during the winter period when the streams and watercourses are "ice" bound, to note the changes taking place as well as to obtain an idea of the rate of flow or the state of aquatic and animal life during this period.

To sanitary engineers and sanitarians, sanitary surveys open up a very vast and at present almost unexplored "field" of operations, and as the population increases (as it does year by year), close investigation of the state of all waters will demand their unceasing attention if the preservation of the public health is to be their principal object.

The government of this province has already set an example to its sister provinces by organizing sanitary surveys on a systematic scale of all its waterways and creeks, and perhaps a review of the methods now being employed to ascertain the conditions that are prevailing will not come amiss.

In the first instance, "waterways" to be surveyed, if within a reasonable distance, are always first visited to gain an idea as to the best means of surveying them in a thorough and expeditious manner to enable the engineer who is employed to make an exhaustive report.

Plans are then obtained of the section or area to be taken in hand, which, if on too small a scale, are enlarged to such a size as shall allow corrections to be made and measurements clearly marked thereon.

"Field sheets" are also prepared, such as will be suitable to meet the requirements of town or country, with the necessary questions printed on, to gather the data it is necessary to obtain and on which the report will be based.

Large plans should be avoided, 24 in. x 20 in. are found the most convenient for outside work, each of which should be marked in "alphabetical" manner and pinned one on top of the other to a light drawing board or on to stout cardboard, which is swung over the back, when not in use, thus leaving the hands free.

Record plans on large sheets should in the meantime be prepared in the office as well as a "Record Book" into which is entered all the information obtained, so that it can be referred to from time to time or when it is necessary to take up the record part of the survey.

The surveys should be conducted at least twice in the same year, but owing to the extreme climatic conditions met with in this country, it is impossible to lay down any hard or fast rules on such a point, so much will depend upon the district, stream and the purpose for which the work is being carried on.

Where work in towns is concerned or such houses affected or likely to affect the survey situated along the banks of streams and creeks, information should be obtained and everything done to gather such data as shall enable a full report to be compiled.

A gauge is placed in the stream and the height of the water is taken, with the hour of the reading as well as the day, month and year, tests are also made as to the rate of flow of the current and the quantity of flow in gallons per second, the course of the current is noted and erosions due to this cause are also marked in as well, whilst large shoals of gravel and such as would be likely to affect the general run of the current are marked in on the plan.

A thorough examination of the banks is to be undertaken with a view to ascertaining the nature of the pollution taking place as well as the nature of any pools left behind which are likely to cause the breeding of flies (especially when near human habitation or from which dairy cows and others might be likely to water at) the bed of the river, creek or stream, where visible, is examined and a note of such aquatic plants growing there, also of the animal life or fish life, as well as that of insects. Soundings in shallow pools may be frequently taken where necessary. This may be taken by means of wading with a six-foot pole or rod marked in feet, inches and half inches, where deeper water is encountered and boats are not available, a waterproof tape with a conical lead may be employed and run over a pole with a small guide pulley at the end, the lead should have a slightly scooped-out bottom which, if greased, will serve the double purpose not only of sounding, but will also give a sample of the bottom which should be examined at the time, or kept for a more opportune moment when a fuller examination may be carried out.

Where sewer outfalls occur these should be noted on the plans with all the necessary measurements taken and, if run out into the river, the angle should be carefully noted.

Sewage fungus should be looked for at these points, and a sample obtained for examination by the chemist, who may be employed to analyze the samples at the labatory, the returns of which will be put in the final report.

Samples.—The writer always prefers to leave the taking of samples till the last, so that there may be as little delay as possible in getting them in to be tested owing to the rapid changes that take place where delay owing to distance is likely to occur, a little addition of formaldehyde or chloroform to the sample for dissolved oxygen test will usually help to keep it in the same state as when taken for about 48 hours.

The bottles to be used should be glass bottles with tight-fitting glass stoppers (for preference) well sterilized, covered with a small piece of cloth tied down. When taking the sample the fingers are to be kept clear from the mouth of the bottle, which should be well rinsed in the water to be sampled and then filled to within half an inch of the stopper.

In conclusion, the writer would suggest that where important surveys are to be made, samples should always be taken and analyzed by a competent chemist, especially when it happens that the survey is being carried out with a view to finding out the actual conditions prevailing in the river as the preliminary step to arranging for a supply of water for a town.

WATER PRESSURES IN LARGE CIRCULAR CONDUITS.

With the expansion that has taken place during recent years in the utilization of water resources, both for power and for industrial and domestic consumption, there has been an accompanying increase in variety of the problems connected with the design of pipe-lines. One that has risen to a degree of importance calling for rapid and accurate solution bears upon the use of circular pipes. The use of conduits of larger diameters has become widespread, although it cannot be said that the stresses to which they are subjected are a matter of common knowledge, or have always been taken into account in the design.

Water powers that were considered economically impossible of development in the past are now being harnessed and brought into commercial use by the installation of long feeder penstocks. Also, increased density of population on every side demands an adequate supply of pure water, with which is frequently associated the necessity of pipe lines of great length and of large carrying capacity. These conditions are likely to develop rapidly as time goes on.

It is true that the use of circular pipes of relatively small diameter has not entailed serious difficulty for the designer. With the use of conduits of larger diameters, under certain conditions, however, various elements of design come in for careful treatment. One phase of the problem has been almost totally ignored. It comprises the large bending moments that are created in the shell of a circular conduit lying in a horizontal position, and filled with water.

This most important phase is dealt with in the first article in this issue of *The Canadian Engineer*, and we feel that we are particularly fortunate in being able to present this analysis by Mr. Hogg. The subject, to our knowledge, has never been treated in engineering literature before.

The article also includes a general discussion of the analysis of the stresses in, and the design of, water conduits, which should prove of interest to the engineering profession.

OTTAWA'S PROPOSED AQUEDUCT.

Ottawa City Council very wisely rejected, last week, the proposal to amend Sir Alexander Binnie's report, substituting a 58-inch pipe line, with a carrying capacity of 33,000,000 gallons, for the 54-inch pipe line that was recommended. (See *The Canadian Engineer*, Oct. 16th, 1913, page 595, *et seq.*) The argument favoring the adoption of a conduit of larger diameter, was based upon the fact that, at the present rate of growth of population, the city would be obliged to set about increasing its water supply in six or seven years, which will be about three years after the line is completed. It is claimed that, with the present rate of consumption ranging from 175 to 190 gallons per capita per day, the city will soon attain a population that will demand a greater daily supply than the 25,000,000 gallons which the proposed 54-inch pipe, emptying into the service reservoir, would provide.

In his report, Sir Alexander Binnie threw particular emphasis upon the enormous waste of water in Ottawa. It was stated that it could be reduced to 100 gallons per head per day; and his report was based upon this figure. Doubtless, measures will be taken forthwith to stop the leaks in pipes and house fittings, since it is plain that,

owing to defects in such connections, over 100 gallons per day is lost for each head of population. Thus, without coercive measures to reduce the quantity actually used by consumers, the present distribution may be improved so that the 54-inch pipe would provide a supply sufficient for many years to come.

What the City Council might well have done, however, would have been to discuss the advisability of a duplicate pipe line for this 235,000-foot aqueduct leading from the outlet of Long Lake to the service reservoir. Although the pipe line, as projected, will be eight or nine feet below the surface of the ground, it must pass through loamy and swampy ground, and has several streams and rivers to cross by means of bridges, the largest of which will have a 150-foot span. Coupled with severe winter weather, these conditions are such as to indicate the advisability of a duplicate line to guard against water famine in case of an obligative emptying of the pipe for repair. A 12-day reserve, which the service reservoir is designed to hold, may be found altogether too inadequate and the time may be too short in which to get equipment and materials to the defective spot in the aqueduct, and the necessary repairs completed.

The water supply of a city is something that demands greatest care to be taken in its design, construction and operation, to eliminate all dangers of interruption for any length of time. A great deal depends upon design. It is not often that the designing engineer escapes criticism if deficiencies appear even after the system has been in operation some little time. In Ottawa's case, duplication of pipe line should be given more consideration at this stage.

THE HIGHWAY COMMISSION AT BELLEVILLE.

No fewer than thirty-five representatives from surrounding municipalities greeted the Public Roads and Highway Commission at its sitting in Belleville on Nov. 4th. Their suggestions were for the most part of a practical nature, showing that the road question has been receiving sound consideration and that the counties are anxious to assist the movement just as far as they possibly can. Among the recommendations brought forward there are few that the Commission can pronounce outside the scope of early realization, if the agitation for better roads throughout older Ontario meets with the recognition that is its due.

A few of the suggestions, expressive of the general feeling of the Belleville meeting, are as follows:—

(1) To prevent a still greater decline in Ontario's rural population, something must soon be done to improve the roads.

(2) A permanent Road Commission should exist, to obviate an undue amount of patchwork in county road building.

(3) Counties should be grouped, for purposes of road standardization.

(4) There should be more Government inspection of roads, and the Government should force counties to begin maintenance duties earlier after construction.

(5) More regard should be shown, where possible, for the lighting of county roads.

The following recommendations of the Road Committee of the County Council of Hastings were presented by Mr. N. Vermilyea, president of the Good Roads Association:—

"That legislation be passed prohibiting the manufacture of new vehicles and the renewal of old ones carrying 1,500 pounds or over with a less width of tire than four inches, and five years only be allowed for changing to the same width the tires of existing vehicles of similar capacity.

"That a tax of fifty cents per horse-power be imposed in lieu of the existing license fee upon all autos up to and including twenty horse-power, 75 cents per horse-power on autos above twenty horse-power and up to and including thirty horse-power, $1 per horse-power upon all autos above thirty horse-power, and that the money so raised be applied for highway improvement.

"That expenditures hereafter upon all county roads and bridges shall be borne one-third by the county in which they are situated and two-thirds by the Government of the province; that it is of supreme importance that the cost of maintenance should be borne in the same proportions as the cost of construction by the county and province respectively; that as we consider county roads should be constructed in such places only as will be in the general interest, we are opposed to a frontage tax; that the highway connecting the producer with the producer's market receive first consideration, and that such roads be selected where the council of each county shall approve."

COST OF OPERATING ELECTRIC TRUCKS.

OF interest to Canadian manufacturers and contractors are the figures contained in a report recently presented at the Electric Vehicle Association in Chicago, on the costs of motor truck operation. The estimates cover a wide variety of sizes and operating conditions. As a matter of fact, the operation of a motor truck is beset with so widely varying conditions—differing with every city, every trade and almost with every installation—as to make figures, as a rule, very unreliable as a guide though, of course, they do frequently tell what certain owners have succeeded in doing. The contribution mentioned above, however, is the work of a special committee, and its figures are based on a large range of electric vehicle installations in various cities. The following is from a table appending the report:—

Capacity, lbs.	700	1,000	2,000
Approximate price	$1,500	$2,200	$2,600
Fixed charges—			
Interest at 6%	$ 90	$132	$156
Depreciation at 10%	150	220	260
Fire insurance at 1%	15	22	26
Liability insurance	100	100	100
	$355	$474	$542
Maintenance—			
Battery upkeep	$170	$180	$200
Tire upkeep	130	150	180
Mechanical parts upkeep	50	60	80
	$350	$390	$460
Garaging—			
Electric power	$120	$140	$170
Storage and washing	180	180	180
Garage labor	100	120	160
	$400	$440	$510
Annual operating cost	$1,105	$1,304	$1,512

Daily cost (312 days)	$3.54	$4.18	$4.84
Drivers per day	2.00	2.00	2.50
Total daily cost	$5.54	$6.18	$7.34
Capacity, lbs.	3,000	4,000	7,000	10,000
Approximate price	$3,000	$3,400	$4,000	$4,500
Fixed charges—				
Interest at 6%	$180	$204	$240	$270
Depreciation at 10%	300	340	400	450
Fire insurance at 1%	30	34	40	45
Liability insurance	100	100	100	100
	$610	$678	$780	$865
Maintenance—				
Battery upkeep	$240	$285	$365	$415
Tire upkeep	230	280	400	600
Mechanical parts upkeep	90	100	125	150
	$560	$665	$890	$1,165
Garaging—				
Electric power	$240	$300	$360	$400
Storage and washing	180	180	180	180
Garage labor	180	200	250	300
	$600	$680	$790	$880
Annual operating cost	$1,770	$2,023	$2,460	$2,910
Daily cost (312 days)	$5.67	$6.48	$7.88	$9.32
Drivers per day	2.50	2.50	3.00	3.00
Total daily cost	$8.17	$8.98	$10.88	$12.32

Edison battery equipment will have lower maintenance and higher power consumption than above.

Depreciation at 10 per cent. should provide one complete equipment renewal in 10 years, which is not figured in maintenance as above.

Interest should strictly be at 3 per cent. as depreciation fund gradually reduces investment.

HANDLING OF IDLE PLANT.

THE systematic methods of handling plant, in the construction of the Panama Canal are still in evidence, despite the fact that much of it has already been retired from service. The *Canal Record* recently published official rules for the laying up of all idle equipment. They are valuable as general information to engineering contractors, who have the same procedure to follow at frequent intervals. They are as follows:—

Locomotives.—Boilers should be emptied and thoroughly cleaned of all scale and foreign matter. Boilers should then be filled with water, leaving space enough for at least two barrels of crude oil or a sufficient amount of crude oil to cover the internal surfaces of boiler and tubes. This oil should be put in at dome, then blow-off cock should be opened up and boiler drained. The same instructions apply to locomotive tanks as to boilers. The front end of locomotives and fireboxes of all boilers should be thoroughly cleaned and brushed off with wire brush and given a coat of tar paint. This paint can be put on with a spray. The coal space on all locomotive tanks should be thoroughly cleaned and scaled and surface given a coat of tar paint. All exterior surfaces of equipment should be painted if necessary, using the standard grade of paint which is commonly used for that purpose. The jackets on all boilers should be given a coat of white lead and tallow. Smoke stacks should be covered with sheet-iron covering made specially for this purpose. Main rods of locomotives should be disconnected and all bearing and bright surfaces receive a coat of white lead and tallow. Eccentric straps and blades should be removed from locomotives and placed with main rods in the cabs, and cabs boarded up. The steam chest cover should be lifted, cylinder heads removed, and all surfaces treated with a coating of white lead and tallow. It will be necessary to remove the valves and pull pistons in order to get at the parts, which should be replaced, steam chest and cylinders closed, and the crossheads blocked in order to eliminate the moving of the pistons in cylinders. The air pumps and the feed pumps on all equipment should be opened up and surfaces treated with a coat of white lead and tallow. The cap on engineer's brake valve on locomotives should be lifted and the surfaces of the valves, etc., slushed with vaseline. All exterior surfaces of cab fittings should be given either a coat of white lead and tallow or vaseline. Interior surfaces of triple valves and injectors need not be treated, as they are brass. Journal box cellars on all drivers and engine truck wheels should be well packed, also journal boxes on tanks.

Steamshovels.—The same general rules for the care of locomotives will apply to steamshovels. All engine pistons, valves, rods, eccentric straps, "A" frame collar and swing circle to be removed; shafts lifted from bearings, wearing surfaces cleaned, doped with white lead and replaced. Boilers should be stripped with lagging, and cleaned as outlined for locomotive boilers. Water tanks should be taken off shovels, inspected, and if found in bad condition they should be scrapped. Roofs should be painted with tar paint; also coal platforms and dippers. Other parts now covered with oil or grease can be protected with a coat of crude oil, which will be sufficient protection.

Unloaders, Cranes, Spreaders, Hoisting Engines, Trackshifters and Piledrivers.—Machinery should be gone over and given a coat of white lead and tallow, as outlined for steamshovels.

Miscellaneous Machinery, Including Shop's Machinery and Tools.—Air pumps and feed pumps on all equipment should be opened up and surfaces treated with a coating of white lead and tallow. All bearings, journals and bright surfaces of all machinery and equipment should be given a coat of white lead and tallow.

PAVING BRICK FROM FURNACE SLAG.

AN extensive industry is being developed in the north of England, at Middlesborough, based upon the utilization of blast-furnace slag. It is described by Mr. Frank G. Bolles in a recent Daily Consular and Trade Report. Several companies are now engaged in the work and are apparently very successful both as to results obtained from the brick as well as commercially. The method pursued in the manufacture of these bricks is as follows:

A suitable manufacturing site is selected near the blast furnaces which are to supply the slag, this plant being connected by an industrial railway upon which the molten slag is carried from the furnace to the molding machine. The latter consists of a metal wheel which may be of any suitable diameter, but which in the case examined was approximately 30 ft., this wheel being supported upon a vertical shaft. The spokes of the wheel are made of round rods and the construction of the wheel

itself is quite similar to the wire-spoked wheel used for vehicles. The metal rim upon which the molds are bolted is approximately three-fourths inch thick and 6 in. wide. In the plant examined this wheel carried 120 molds 9 ins. long, 3½ ins. thick, and 4 ins. deep, which is the standard size for paving brick. A variety of other molds are used, but the bulk of the work is of the paving-brick size. The molds are made of two pieces, the front end or right side being an arm in one piece which is bolted to the rim of the wheel, while the left side, back end, and bottom is another piece. The latter is hinged to the part which is secured to the rim of the wheel and held for casting purposes by a catch on the front end of the stationary piece. On the right side of the mold is cast a lip which assists the operator in more readily striking the mold when pouring the hot slag. Before casting the molds are dusted with a powder, the appearance of which would indicate it to be Portland or other cement.

The car which carries the slag is of plate steel with a fire-brick lining, the top being covered over with a removal cap, in the centre of which is a hole approximately 18 ins. in diameter, through which the slag is poured when the car is filled at the furnace. At the bottom of this car is a tap similar to those used upon blast furnaces. The car of molten slag is run alongside the wheel, the trough to the tap extending over the molds; the clay plug in the tap is knocked out and the molten slag runs into the mold. As soon as it is filled an operator, by means of a handwheel mounted upon a sheet-steel heat deflector and connected through rods and miter gears to the centre of the molding wheel, turns the latter so that the next mold comes under the flow of hot slag, and so on until all the molds are filled. By the time that the wheel has made a quarter revolution the cast brick has sufficiently cooled to that they may be dropped out of the molds by knocking off the catch which holds the bottom in place.

As soon as they have dropped to the ground they are taken by laborers to the annealing furnaces, into which they are thrown in a promiscuous heap. These furnaces, of which there were six in the plant examined, held approximately 1,100 brick at one charge. The heat retained in the brick when they are thrown into the furnace, together with a very small amount of fuel, again brings them to a cherry red, and as soon as the furnace has been filled it is closed and allowed to cool gradually, 24 hours usually being required before the bricks are removed.

The capacity of the slag car is approximately 3½ tons, from which 360 to 400 paving bricks are made. The bricks, when cleaned up, having all of the rough corners knocked off which have been left in the process of casting, weigh about 14 pounds each. These bricks are proving very efficient for street paving and are being exported to Canada, the United States, and many other countries.

OIL VERSUS COAL AS FUEL.

According to British Trade and Commerce reports, opportunity has been taken of the considerable development in the use of oil as a fuel in the place of coal to revise the rules in connection with the burning and carrying of oil fuel, the flash point of which does not fall below 150 degrees Fahrenheit. These rules were originally adopted in 1902, and advantage has been taken of the experience since acquired to bring the regulations up to date.

CROSS SECTIONS OF BREAKWATERS TO WITHSTAND WAVE ACTION.*

By Col. Frederic V. Abbot,
U.S. Corps of Engineers; M. Am. Soc. C.E.

TWO prime factors, exposure and cost, determine the best form of cross section to adopt for a breakwater. Exposure varies with the fetch of waves and with the depth of water at the structure and the front between it and the open ocean. At Charleston, S.C., with moderate depths and outlying shoal areas to break the full force of the ocean waves, a rubble mound cross section has served well for the jetties, built to deepen the channel, but serving also as breakwaters to reduce the force of waves in the jetty channel. In construction care was taken to avoid using small stone for a hearting and covering it with selected large stone, as has been frequently done in Europe. Run of the quarry was used up to about low-water, the drilling and blasting being conducted so as to produce as large a percentage of stone of 7-ton weigth as possible. Above low-water level a skeleton was made of stone from 1 to 7 tons in weight dropped directly along the axis up to a height somewhat above high-water level, and left with side slopes as steep as they would stand; this skeleton was covered with quarry run also dumped directly along the axis with natural side slopes up to a height of 10 or 12 feet above high-water. The first heavy storm would knock this grouting and the upper part of the skeleton down, beating the smaller pieces in among the undisturbed larger pieces of stone forming the skeleton, and distributing the balance on the slopes. The grouting was then replaced to the former height, taking this time much less stone than at first, and a new storm was awaited. It generally proved to be necessary to repeat this process three times before the cross section assumed a final permanent form, with crest approximately at high-water level. Writing from memory only, it is the writer's impression that at the outer ends of the Charleston jetties, 20,000 feet from shore, the mound was ultimately nearly 90 feet wide at mean low-water with a crest about 5 feet above; the crest, which was very smooth and level, was about two-thirds of the way from the seaward to the harbor side of the 90 feet lying between low-water levels on the two sides. At depths greater than 15 to 25 feet on seaward side, depending on the local protection afforded by outlying shoals, the slopes were nearly 1 on 1, and from those depths to the crest the seaward surface was convex toward the sea, the slope becoming very gentle for the 2 feet immediately below the crest. The upper surface was singularly uniform and smooth, considering the great size of many of the stones. The harbor side was similar but much steeper throughout. This form of cross section permits waves to mount the slope and fall over into the harbor with the least abrasion and injury to the structure, and it has resulted from the action of the very forces it is intended to resist. The engineer has simply supplied material, which waves have molded into final shape. The stilling effect of such a structure is not as great as that of one designed to throw the entire wave back to the front, but, except in very heavy weather, the water between the Charleston jetties is not rough enough to inconvenience any vessel adapted to ocean traffic. An advantage of this method of construction is that each part

*From Col. Abbot's article on the subject in "Professional Memoirs" for Nov.-Dec., 1913.

of the structure has a cross section just sufficient for its individual exposure, and therefore no stone is wasted to give a section stronger than is needed; repairs are extremely easy if a shifting of the other shoals exposes any part of the superstructure to heavier seas than existed there when it was built. The last stone was deposited on the jetties about twenty years ago, and I am told that there has been no sensible degradation of the crest

enormous quantities of stone. Failures prove more than successes, and it is possible that at that point some form of cross section like the Columbo sloping block or the Sandy Bay coursed squared stone might have been cheaper in ultimate cost. The preparation of a suitable flat base for such an accurately laid superstructure would, however, have been vastly difficult and costly on the Columbia River bar.

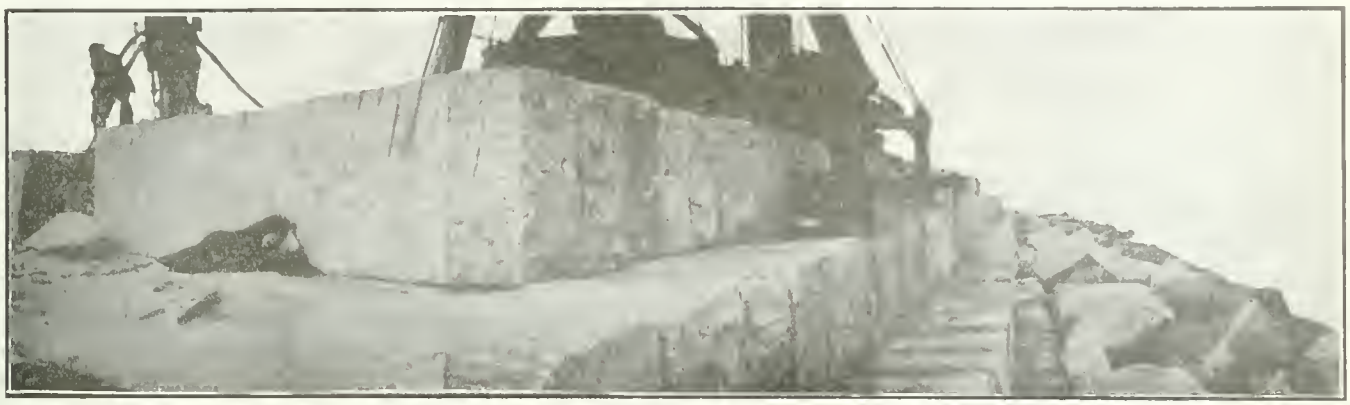

Fig. 1.—Drilling Holes for 30-ton Capstones, Sandy Bay Breakwater.

level in that time, although a number of West Indian hurricanes have passed over the harbor and done vast damage to the city and to shipping in the inner bay.

The Galveston jetties were originally built with rather small stone hearting covered with heavy stone sides and cap; the storm of 1901 produced disastrous effects; as soon as the capping or side covering was broken the interior washed out and the whole structure ravelled and collapsed for considerable distances.

At the Columbia River jetties the exposure and outlying depths are so great that a random cross section somewhat similar to that at Charleston has so far proved impossible to maintain above mid-tide without using

At Point Judith, where the exposure is perhaps comparable with that at Charleston, a moderate rubble mound, with a superstructure of large blocks set to form a regular cross section, with predetermined surfaces of heavy rubble on the top and seaward side, has stood for years with comparatively small repairs, but when they have been necessary the regularity of the structure has made them costly because a number of stones, only slightly displaced, had to be taken up and reset to restore the bond and to avoid conspicuous irregularities. Where lines are straight, or surfaces are planes, the eye is quick to detect any elevation, depression, or bulge, and this is a serious disadvantage of too regular outlines in break-

waters where the forces in action are so great as to make deformations probable. Where integrity of the structure depends on bond or a smooth surface for waves to mount on, such deformations are not only very unsightly but seriously impair capacity to withstand subsequent storms.

At Gloucester, Mass., a very carefully built breakwater, with a superstructure of extraordinarily narrow cross section (side slopes of 1 on 0.7) has safely withstood storms of great severity and waves of great force, but the breakwater does not receive the unbroken force of the heaviest waves. It has recently received a wide sea apron of 5-ton rubble, to break up the force of waves before they strike the superstructure proper. In January, 1913, a storm moved a number of cap stones. They have been reset, and dowelled to the course below, to prevent sliding.

At Sandy Bay conditions are extreme. For long distances the depth of water is 800 feet; the exposure is to the northeast, from which direction come the heaviest storms; there are no outlying shoals to protect the part of the breakwater lying in the deepest water. A heavy rubble mound forms the base of the structure. An attempt to bring it up to 18 feet above mean low-water (9.4 feet above high-water) by simple heavy random blocks failed on the first attempt, and the experiment was not repeated. It is to be regretted that it was not pushed further, for it is possible that ultimately, as at Charleston, S.C., a cross section would thus have been secured exactly

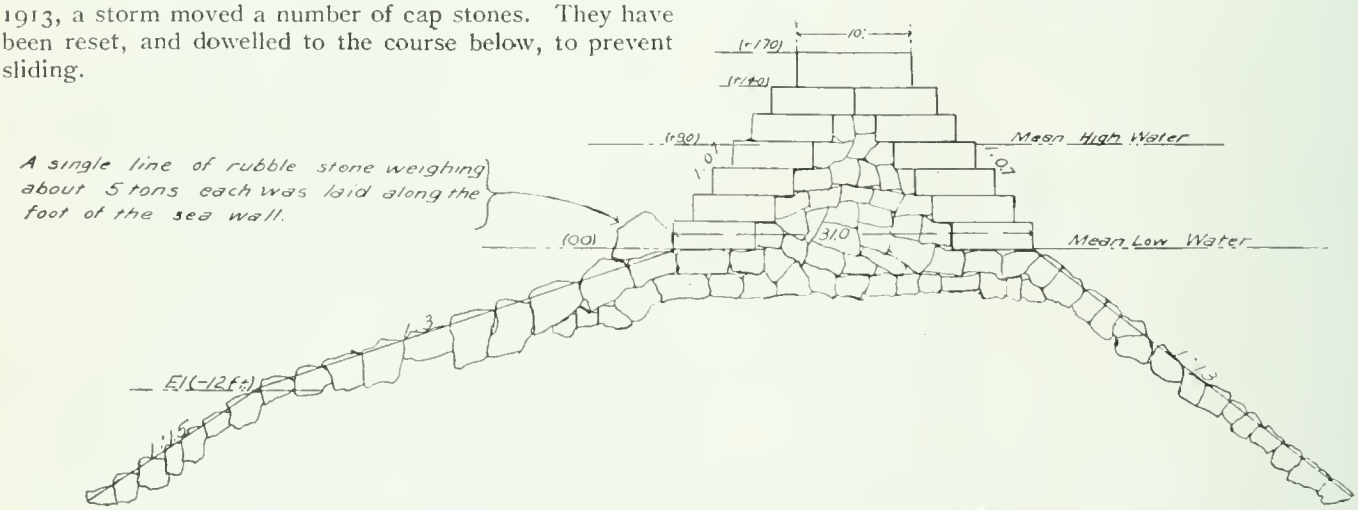

Fig. 4.—Cross Section of Dog Bar Breakwater, Gloucester, Mass., as Constructed.

NOTE:—*Caps* are 3 foot rise, vary in width of face from 5.2 feet to 4.6 feet and weigh 8 tons to 11.5 tons with an average weight of 9.25 tons. *The walls* are in six courses in a rise of 14.0 feet or theoretically 2.33 foot rise per course. In construction the stone was quarried 2.2 foot rise for the first 5 courses, and the 6th course was cut to the rise necessary to secure the approximate grade of bed for the caps, resulting generally in slightly heavier stone in the 6th course.

The length of stone in the walls was specified to be not less than 7 feet nor more than 8 feet. The dimensions and weights of stones computed on an average length of 7.5 feet are as follows:—

	Sea Wall.	Harbor Wall.
Maximum width of face	5.6 feet	6.0 feet
Minimum width of face	2.5 feet	2.2 feet
Average width of face	3.4 feet	3.2 feet
Weight of maximum stone	8.2 tons	8.7 tons
Weight of minimum stone	4.0 tons	3.2 tons
Weight of average stone	4.9 tons	4.7 tons

Substructure:—Specifications required that in the seaward slope no stone should be used weighing less than 3 tons and that average weight of stone in each cargo should be not less than 4 tons. In rubble mound generally and harbor slope the stones ranged in weight from 500 pounds to 4 tons.

adapted to the exposure. The depth is so great, however, that an enormous quantity of stone would have been needed to give sufficient base for the part affected by wave action, which here extends to 30 feet below mean low-water, as shown by actual surveys. In designing a superstructure for this breakwater, all engineers have attempted to keep the width of foundation a minimum on account of the great quantity of stone needed to fill out the slopes of the substructure in 80 to 90 feet of water. From the bottom up to a depth of 30 feet below mean low-water the mound stands stable with slopes of 1 on 1; from that level up to mean low-water heavy rubble seems

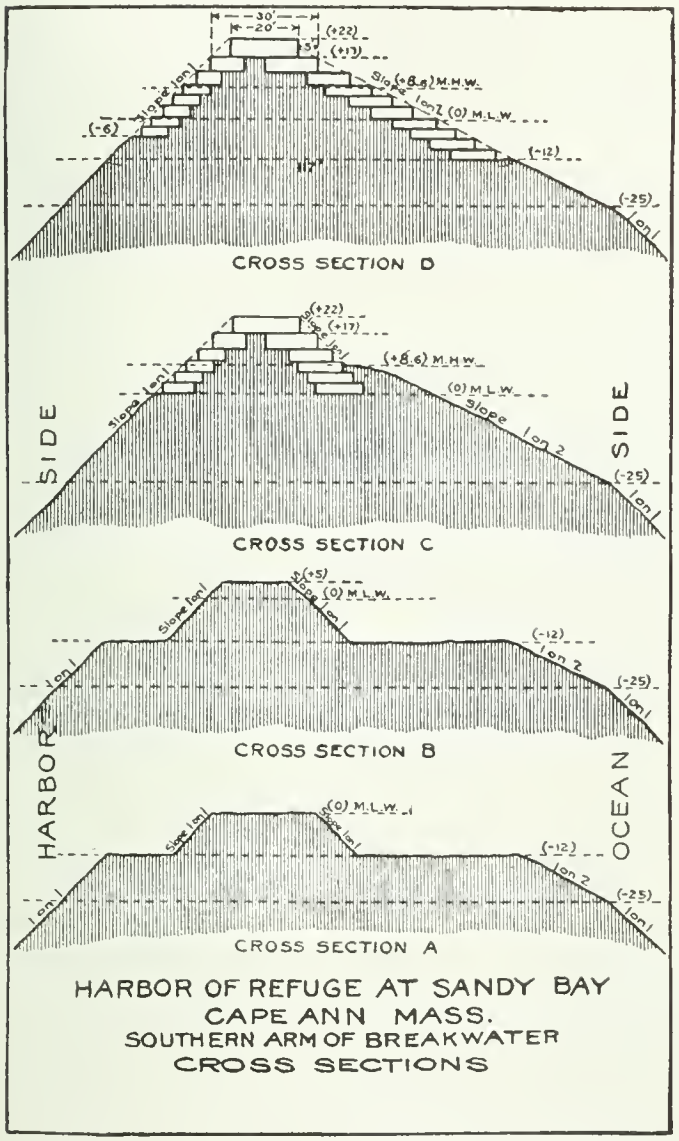

Fig. 5.—Sandy Bay Breakwater Cross Sections.

to stand safely at about 1 on 2. The first experiment with closely laid, uncut dimension stones was to set by divers on the seaward side a row of heavy rectangular headers at level—12 referred to mean low-water, and a similar row at level—6 on the harbor side, filling between the rows with medium heavy rubble. Successive rows of dimension stone blocks were laid on these foundation rows, so as to give a stepped seaward slope of 1 on 2, and a stepped harbor slope of 1 on 1 up to level + 17, where the two rows were only about 5 feet apart at the inner ends of the headers. Capstones, 20 feet long and 5 feet rise, were set to bond the two walls. This superstructure withstood several winter storms, but in 1908 displacement of stones (see illustrations herewith) showed that for a permanent superstructure the cross section was insufficient.

The latest form is due to Col. Edward Burr, who kept the harbor side of the superstructure unchanged, except that the lowest course is now at low-water and not 6 feet below. The capstones are as before, but each is supported against sliding toward the harbor by a 2-inch dowel pin set in a hole in the underlying course of the harbor wall, and solidly grouted in place. Below the cap the seaward face is built in steps sloping 1 on 1 and not 1 on 2, with the main object of giving greater lap of the upper stones on those in the lower courses, to resist the tendency to pull out to the front—the way in which the prior section failed most signally. In both harbor and land walls he stopped the dimension stone steps at mean low-water in order to secure better inspection of the bedding of those most important blocks. The berm created by drawing back the foot of the seaward slope was utilized by using is as a shelf to hold 10-ton rubble, which was brought up to high-water level in front of the dimension stone. The rubble tends to shatter the waves before they reach the superstructure proper.

In 1909 a short section of this new superstructure withstood almost unchanged the heaviest storms of the past twenty years, and in accordance with recommendations of the Department, Congress has appropriated sufficient funds to build 800 feet of this cross section, of which 200 feet are on the western arm, and 600 feet are on the southern arm. This will be a sufficient length to develop the full destructive force of waves to which the southern arm is exposed, and if it prove sufficiently resisting the rest of that arm can safely be built to that cross section. There is an outlying shoal, submerged from 30 to 10 feet in local peaks, which gives that arm some protection. The western arm, however, crosses a wide, deep depression in which there are no depths less than 80 feet between the structure and the ocean to the northward and eastward; here the exposure will be the maximum, the fetch being the whole width of the Atlantic Ocean, and experience gained in the work will be the only safe guide for the officer charged with building the part of the superstructure opposite to this depression. The writer's own inclination would be to make the superstructure like the rest of the work, if found practicable, but to widen out the berm and the rubble front slope by the deposit on that side of large quantities of the heaviest granite rubble that could be bought.

The writer believes that Congress has been wise in suspending work on the superstructure of Sandy Bay until such time as an exceptionally violent easterly storm of some days' duration gives further data on the sufficiency of the present form, which has safely resisted all waves that have so far come against it.

ELEVATOR CAPACITY OF THE G.T.P. RAILWAY.

At present there are on the G.T.P. Railway in Manitoba 25 elevators with a capacity of 757,000 bushels; in Saskatchewan, 178 with a capacity of 5,350,000 bushels; in Alberta, 25 with a capacity of 745,000 bushels; and at Fort William, the largest elevator in the world with a capacity of 5,750,000 bushels. For the prairie provinces, the total capacity is 6,852,000 bushels; including the Fort William elevator, the grand total on the G.T.P. Railway is 12,602,000 bushels

THE TREATMENT OF UNSURFACED ROADS.

IT is stated that there are 2,100,000 miles of roads throughout the United States that are unsurfaced, or rather, that have never been re-surfaced. These roads are composed of materials which run from the finest silt to the hardest granite, and the treatment of one will naturally be entirely different from the treatment of another. It would be difficult to ascertain the various soils or natural earths that go to compose the wearing "surface" of these unsurfaced roads. Yet, they must be carefully maintained, owing to the absence of suitable surfacing materials in numerous sections of the country, and the high cost of handling by railroads, preventing their being surfaced with stone, gravel or other suitable material.

At the American Road Congress in Detroit, Mr. W. S. Keller, State Highway Engineer of Alabama, read a paper dealing with unsurfaced roads, and their maintenance. He divided this type of road into three classes, as follows:—

First, the ordinary country road opened when this country was young, leading from one settlement to another or from a farmer's home to that of his nearest neighbor. These roads were not opened through any process of law, in fact, there was no law governing roads in those early days, but by following trails of least resistance, removing trees and such rocks as would not permit the axles of wagons to clear, the pioneers of this country made it possible to travel, in a way, from place to place. We have many roads in Alabama now in use that were opened and traveled during the wars of long ago. Of course, such roads were opened hurriedly and little or no attention was given to grades or alignments. Settlers, taking advantage of work that had been done, built their homes along these military roads or traces as they are frequently called. In the construction now of more modern roads, it is difficult to better the alignment of these roads on account of homes, churches and schools which have been built close to these highways. However, in many places, these roads have been and are being changed to meet the demand of traffic of to-day. The genuine bad roads of the South belong solely to this class. They cannot be maintained for the reason that they have never been constructed and the great amount of work necessary to keep them in passable condition disheartens the man who by law is compelled to work them. Until these roads are re-located, avoiding heavy grades and marshy bottoms, sharp angles and useless twists and graded so that they will have good drainage, we may expect them to be bad.

The second class of unsurfaced roads are the ordinary graded earth roads which have proper alignment, grade and drainage. The construction of an earth road is simple, but sometimes the simplicity of it causes the average county commissioner or supervisor to overestimate his ability as a road builder. The proper construction of an earth road consists first of a careful inspection by the proper official to determine what beneficial changes in grade and alignment can be made, taking into consideration initial cost and cost of maintenance. The centre line and grade of the road should be established by an engineer. After the centre line has been established and width of road bed agreed on and grade established, construction work can begin. The proper and efficient grading force for the work should consist of a foreman, eight or ten good two-horse teams with drivers, one wheel and one drag scraper for each team and one extra wheeler and drag for emergencies, one good railroad grading plow, one grading machine, one split-log drag, one dump man and one loader with five or six extra men for grubbing and other work. The foreman should be an experienced grading man who understands handling earth and knows when it is proper to use drag scrapers, wheel scrapers or wagons. The road should be so graded that the ditches or gutters are parallel with the centre line of the road and uniform distance from it. When completed, the road should be uniform in width and surface should be smooth and even, free from holes and high places with a uniform crown with a fall of one inch to one foot from centre to gutters. On grades this ratio of fall should exceed that of the grade to such an extent that water will readily flow to the ditches instead of down the road. Drain pipe should be freely used and no water should be allowed to flow over the road if it can be avoided. In some cases it is not practical to build the road above high-water. In such cases danger signs should be posted showing at what stage the water becomes too high to ford the stream.

We have in the South nearly every kind of soil from sticky gumbo on the one hand to coarse sand on the other. The methods used for improvement of roads through a section of one will not do altogether for the other. The worst roads by far that we have in the South are in our rich and fertile prairie lands where, unfortunately, there is very little road building material to be found. This soil readily absorbs water and becomes very sticky after rains. It expands freely and dries rapidly when the sun shines and becomes very hard under the tamping effect of teams and vehicles. From observation and experience I have learned that these roads of all others require a very high crown and the driving surface should only be wide enough to allow two vehicles to pass. If a road is narrow with a fall of not less than one and one-half inches to the foot, water will shed rapidly to the ditches and the entire surface will dry out quickly. A road of this kind can be constructed quickly and at little expense, except where grades are to be reduced or bottoms filled with a grading machine, or even with a split-log drag. The latter method will require more time, but in the end will be found to be very satisfactory. No earth road can be maintained in good condition unless it is so constructed as to drain well and unless it is kept free from ruts and holes.

The third class of unsurfaced road which we frequently have to deal with are those in sections of country where the soil or earth is really road building material, composed either of gravel, sand-clay or top soil so that when the road is graded it is, in fact, surfaced. Where this condition exists, splendid roads can be built at a minimum cost.

The maintenance of unsurfaced roads is radically different from the maintenance of surfaced roads. For instance, the patrol system used on macadam roads would be entirely inadequate for earth roads. One man can keep up two or three miles of macadam road where he would unquestionably be unable to keep in good condition a like amount of unsurfaced road. With the use, however, of a team and drag, he would be able to keep in good condition twenty miles of ordinary graded earth road. Some very zealous advocates of the drag claim everything for it, from the removal of stumps and rocks to the ditching of roads. I am a great believer in the drag, but from experience, I know that obstructions must be removed and proper drainage provided for before

it is effective. It has been difficult with the road men of the South to convince county authorities that this little machine is of value. The writer, when in charge of road work in a Tennessee County, inaugurated a system of dragging that proved very successful. Ten roads were graded a distance of three miles each. The grading was completed in November. With surface of these roads fresh and loose, it was a foregone conclusion that the winter rains would soften them to the extent that they would become impassable under heavy traffic. Contracts were made with a farmer on each of these roads to keep them dragged during the months of December, January, February and March and the price paid was 30c. an hour for a man and team. The county furnished the drags. As an inducement to the men to do good work, the county offered prizes of $25, $15 and $10 for the best kept roads. Specifications for dragging and rules governing the contest were furnished each contestant. One important rule was that the prizes would be awarded to the men who kept their roads in the best condition at the least cost. In order that the engineer might keep in close touch with the work, postal report cards were furnished each man and they were required to fill them out every Monday, showing the distance dragged, hours consumed and cost for the previous week, and mail them to the office of the engineer. In this way it was practically impossible for a dishonest man to render an account for more time than he really consumed without it being detected or if he worked more than was necessary, the reports of the other contestants, when compared with his, disclosed it. On the other hand, if one should be neglecting his work by not dragging sufficiently it was likewise detected. This thirty miles of road was kept in splendid condition despite the fact that two heavy snows fell during the four months. The most interesting fact connected with the contest was the road that was awarded first prize cost the county only $15, or $5 per mile.

In many Southern States the roads are maintained, or at least are supposed to be, by what is known as statute labor, which means a man subject to road tax may work out his tax under the direction of a beat or district overseer. Such labor is practically worthless, and few men are required to work out the stipulated number of days. As it seems to be impossible to entirely abolish statute labor, the question that confronts us now is, what is the best system coupled with this labor to use in the maintenance of our roads. Good results have been accomplished in several counties in Alabama by putting the work in the hands of a few regularly employed foremen who give all of their time and attention to the work, instead of leaving it to many beat overseers who work when it suits their convenience, or do not work at all when it suits them, as it usually does. These foremen are furnished with two or three teams with regular drivers, wagons, scrapers and grading machines, split-log drag and necessary small tools and as many beats or districts assigned to each as he can work. A census is taken in each foreman's territory at the first of the year of all men subject to road duty, and he is furnished with a list of names and is required to work every man who has not paid the required amount of cash into the county treasury in lieu thereof. No foreman is allowed, under penalty of dismissal, to receive cash from work hands, but such hands as desire to pay must make their payments to the proper county official at the court house. This method has proven good in most cases, but as a general thing the best results cannot be accomplished by permitting men to work out their road tax.

TRIANGULAR RAILWAY TIES.

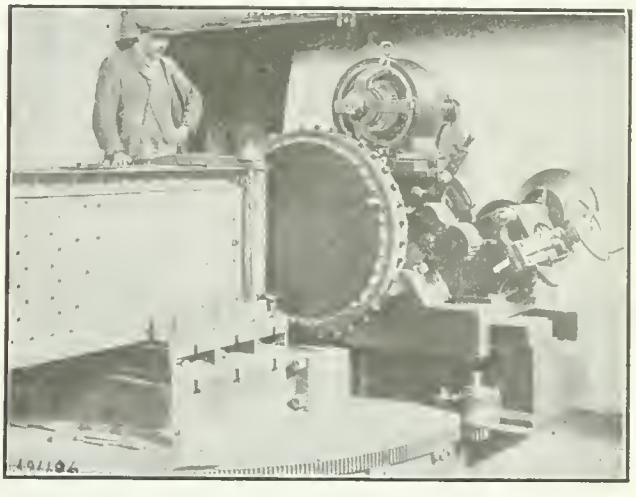
During the past twelve years upwards of four million triangular ties have been laid by the Great Northern Railway, from 150,000 to 200,000 now being inserted annually. Ties of this shape have an advantage which the following description will disclose:—

In their manufacture either two or four ties are cut from a log, timber cutting four ties being preferred, as the annular rings of such ties are convex and provide better drainage. After a log is squared it is cut diagonally into either two or four pieces 16 in. long on one side and 8 in. in depth. Triangular pieces 2 in x 2 in. in size are cut from each of the two upper corners, leaving the upper face of the tie 12 in. wide. The ties are 8 ft. long. They are treated with a 6 per cent. solution of zinc chloride, equivalent to an injection of ¾ lb. of zinc chloride per cubic foot of timber.

It will be noted that ties of this type are more or less self-tamping, especially at the rail ends, and it has been found to reduce somewhat the expense of joint maintenance in gravel ballast. When not used in conjunction with the ordinary rectangular ties, the triangular tie is believed to give promising results, as some of the best track now in use is thus carried.

MOTOR-DRIVEN ROTARY PLANER.

The accompanying illustration shows an interesting form of planer for very large work, such as facing the ends of columns, cast-iron bed-plates, stringers, etc., and machining engine frames and other heavy castings. The cutting tools are arranged in a circle, which rotates when in operation.



Rotary Planer, Electrically Driven.

The machine illustrated can handle work 40 inches wide and 6 feet long. It is mounted on a circular base, on which it can be turned, and thus increasing its range of operation. It is manufactured by the Newton Machine Tool Works, Philadelphia, and is driven by a Westinghouse motor.

TELEPHONE FROM HOLLAND TO ENGLAND.

A submarine telephone is to be laid between Holland and England. The length of the cable will be 105 miles. According to the present project, the total expense will be near $3,000,000, and will be borne conjointly by the two countries.

SEWAGE PUMPING MACHINERY AND APPLIANCES.

By Gerald Priestman,
President, Merritt Hydraulics Company, Philadelphia, Pa.

Various types of sewage pumping apparatus are in general use, each type being adapted to its own particular work and the selection in any one case must rest largely upon the decision of the engineer. The pumping of sewage differs from the pumping of water in that provision must be made when handling sewage, to take care of the solids, grit and any foreign matter—rags, sticks, etc., which may enter the pump. In other words, the sewage pump or lifting apparatus must be entirely reliable. A shut-down may affect the health of a whole community.

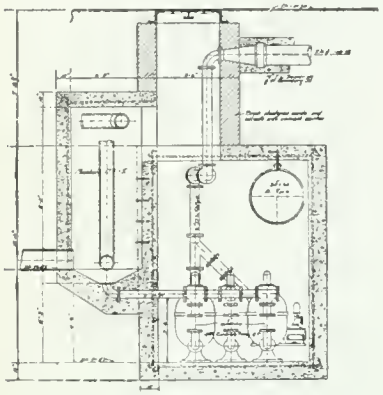


Fig. 1.

Pneumatic Ejectors.—Since all rubbing surfaces or moving parts are eliminated and the sewage is lifted entirely by a piston of air, the pneumatic ejector is well adapted to pumping crude and unscreened sewage. Fig. 1 illustrates a typical isolated sewage pumping plant with three Priestman ejectors and air tanks installed complete in a pit below the street level. An installation of this kind would be made, for instance, to pump sewage from a low lying district of a sewerage system up to a main outfall sewer, saving the excavation and construction work necessary to lay the large main sewer at a deeper level so as to permit drainage by gravity.

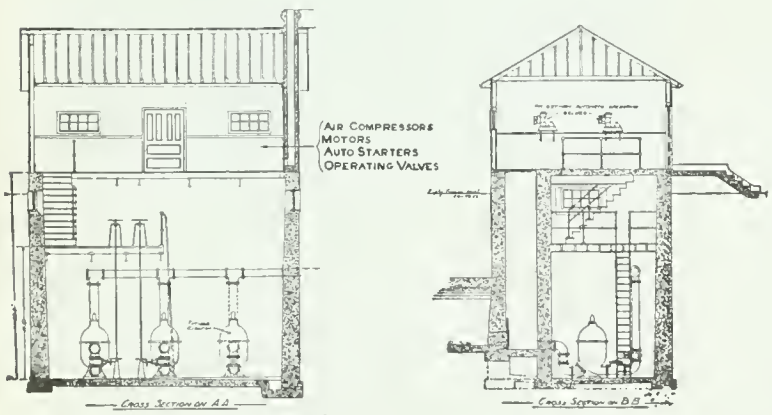

Fig. 3.

Air is supplied from a central compressor plant furnishing air to other similar ejector stations or else for other work. Besides the air tank and ejectors there is also installed in the pit, the ejector operating valve. With this type ejector, the air valves may be located at some convenient and accessible place near the top of the pit and are independent of the ejector bodies themselves, being connected with them by small piping only. The operation is as follows: Sewage gravitates to the ejector bodies; as it rises to the top it entraps and compresses the air present in the small bell. This bell is connected by small piping to the operating valve. The slight compression acting on a diaphragm in the valve is sufficient to operate it so that the main air valve is opened and air is admitted to the ejector to displace and discharge the sewage. The valve is also designed and set so that the air supply is cut off after a predetermined interval before all the sewage has been displaced so that the remainder of the discharge takes place while the air is expanding and the greatest economy is secured.

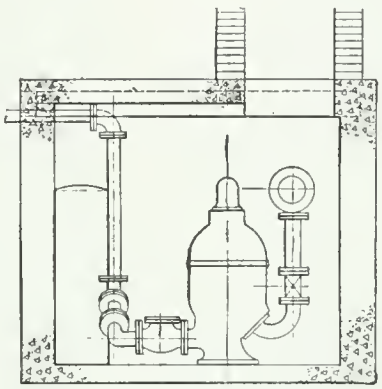

Fig. 2.

Fig. 2 shows another isolated compressor station of somewhat different arrangement and with only one ejector. Where there is only one pumping plant to be installed a complete ejector plant with motors, compressors and auxiliaries is installed in a suitable station, as shown in Figs. 3, 4 and 5. In Fig. 3 the ejector proper is in the pit below the street surface, while the air compressors, motors, auto starters and operating valves are in the house immediately above the pit. The advantage of operating valves which may be located at a distance from the ejectors, is apparent; the valves are located above the street level along with the compressors and auto-starters, where they can all be readily inspected and oiled by the engineer. Fig. 4 shows the operating valves located on the wall to the right of the small com

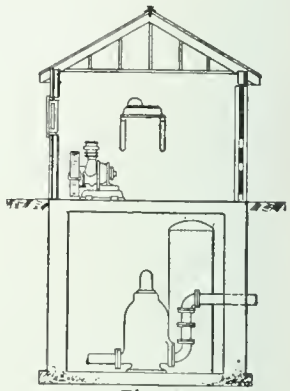

Fig. 4.

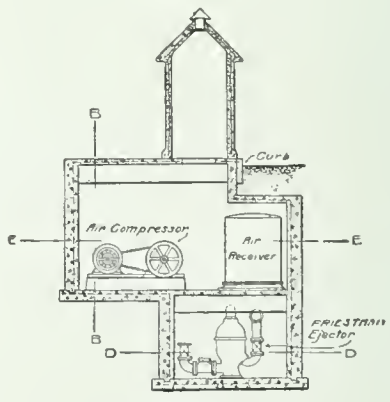

Fig. 5.

pressor, both above the street level, while the ejector and air tank are below in the pit. Fig. 5 shows a complete system below ths street level in a very compact station.

The advantages of the pneumatic ejector have already been pointed out, namely, the absolute reliability of operation depending on the fact that the power is transmitted, not

by plungers, pistons, impellers, screws or similar devices, but by a piston of compressed air. The mechanism for opening the valve to admit the compressed air as, for instance, a

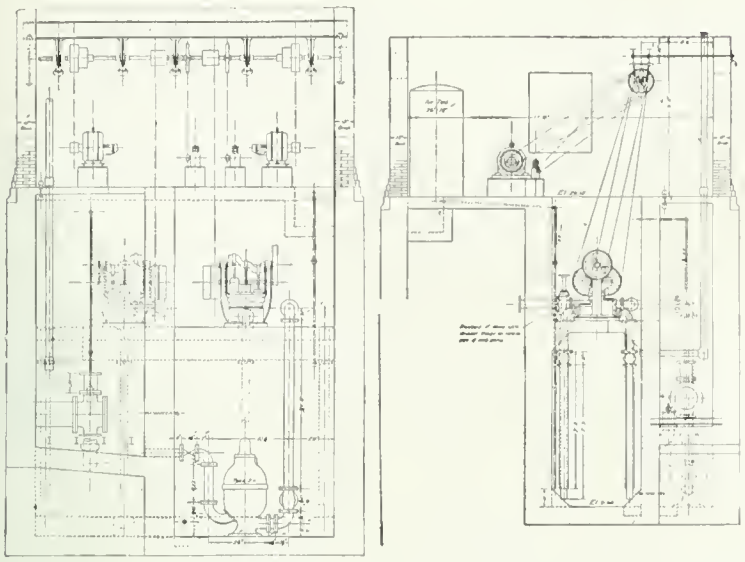

Fig. 6.

float rising with the sewage, may also be replaced by a piston or spring of compressed air which acts upon a suitable diaphragm in the valve mechanism. By this arrangement all moving parts are entirely eliminated in every stage of the operation of the ejector, nothing coming in contact with the sewage but air.

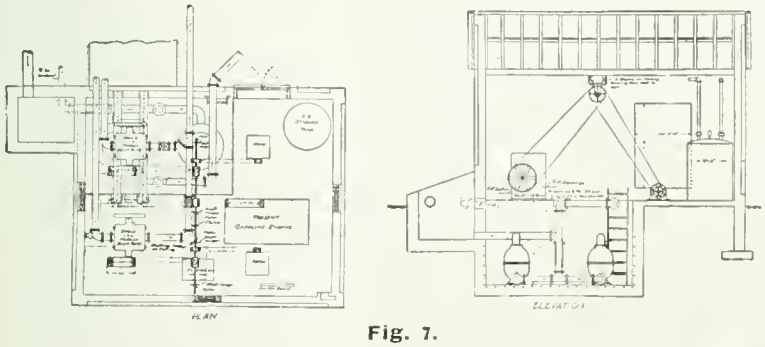

Fig. 7.

But while the pneumatic ejector is very reliable, it is open to some objection on the grounds of inefficiency in large plants operating continuously. In small plants, the reliability of the pneumatic ejector and the fact that it handles crude and unscreened sewage and thus requires no attendance, cleaning of screens, and is entirely fool-proof make the question of efficiency of minor importance. This is even more the case where the sewage flow is intermittent. The compressor automatically maintains the air supply in the tank and when there is no demand the air compressor is shut down. The ejector does not operate until it is filled and it may discharge once an hour or twice a minute, depending upon the rate at which sewage gravitates to it. On the other hand, a small pump of the centrifugal or plunger type may be operating for long periods at far under its full capacity, thus underloading the driving motor as well, with resulting fall in efficiency.

The main reason for the higher efficiency of the pump, as compared to the pneumatic ejector, is that with the pump the drive is direct, whereas, with the pneumatic ejector the driving motor must first compress the air, which in turn discharges the sewage, but an improvement in the efficiency of ejectors is obtained, however, by using the air expansively. By cutting off the air supply at a pre-determined point expansion occurs during the discharge of the remaining volume, so that the air is released from the ejector body at a pressure approximating that of the atmosphere instead of the full pressure of the air in the storage tank.

Centrifugal and Plunger Pumps.—If the sewage is thoroughly screened, a centrifugal pump will handle it at somewhat lower efficiency than that when handling pure water, as the solids and grit and grease which cannot be screened out cause corrosion and incrustation of metal parts. Screens must always be supplied, but even these will not prevent rags and other foreign matter from entering the pump impellers where they are passed with difficulty and very often become entangled and cause vibration and reduction of the pump capacity, and eventually requiring a shut-down.

By making the screens finer, a larger proportion of the solids may be prevented from entering the pump, thus increasing its reliability but, on the other hand, necessitating more frequent cleaning of the screens and more careful attention to the working of the plant. The

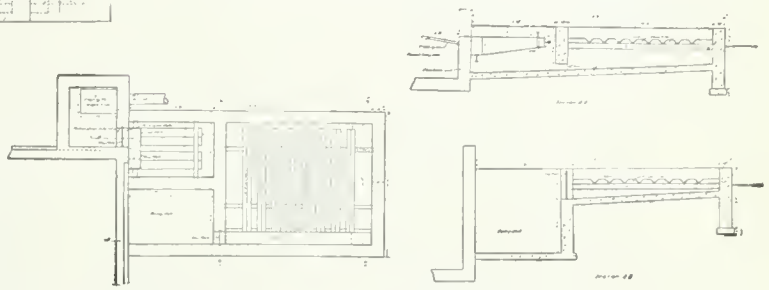

Fig. 8.

accumulation of screenage becomes foul and dangerous to health and the removal of the screenings themselves is costly and troublesome.

Priestman Natural Compound Pumping System.—The ordinary stationary screens have not proved satisfactory, as pointed out, because they require constant attention and become rapidly choked and the removal of the screening is very objectionable and costly work. But screens cannot be done away with or else the pumps will clog. The Priestman natural compound

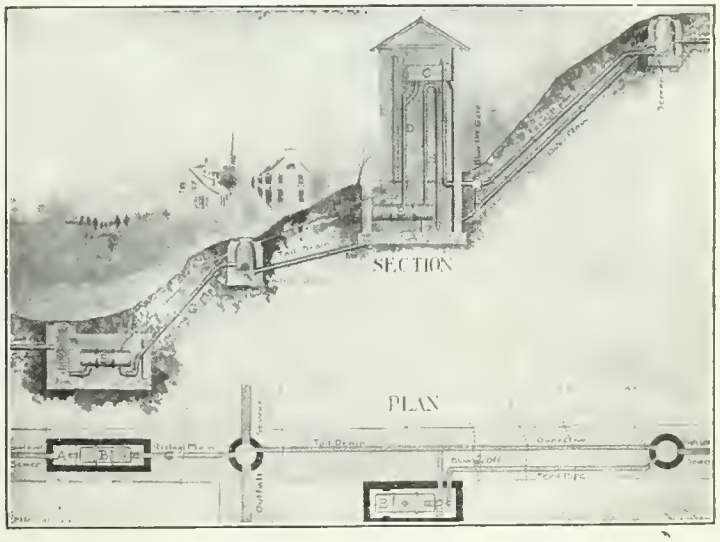

Fig. 9.

pumping system has been perfected in order to overcome these difficulties by separating the solids in the sewage from

the liquids by pre-tanks and then lifting them separately by pumping apparatus best adapted to each service from the standpoint of both reliability and efficiency.

Instead of the ordinary screens the solids are separated out by pre-tanks in which baffles, collecting weirs, self-cleaning screens, etc, are so arranged that the solids are retained in one portion of the tank and the clarified liquid passes on to another. The solids, which make up only a few per cent. of the total volume, gravitate into Priestman pneumatic ejectors and are discharged by compressed air into the delivery main

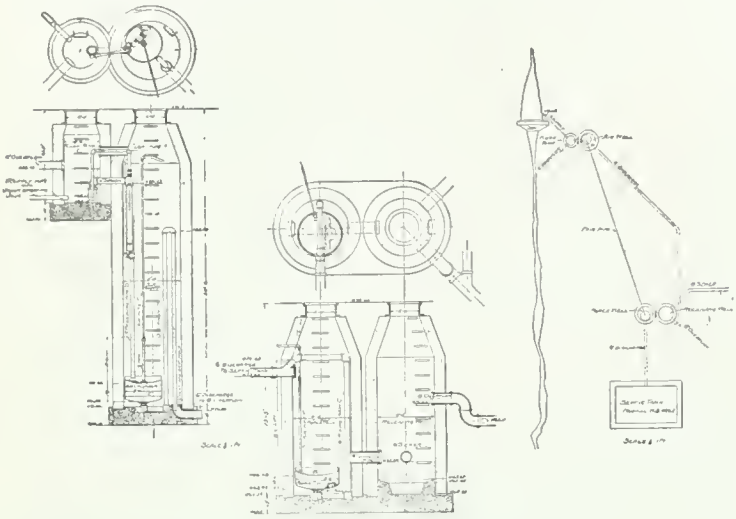

Fig. 10.

by-passing the pump or else to a separate discharge pipe. The clarified liquid is pumped by either high efficiency centrifugal or plunger pumps. The pumps can be driven by motors, gas or oil engines or steam turbines. The air compressor is small and may be readily driven by belting or from the shaft of the main driving motor or engine.

Figs. 6 and 7 show the sewage pumping stations designed on the Priestman natural compound pumping system comprising Priestman ejectors for the sludge and high efficiency triplex plunger pumps for the clarified sewage. Instead of the plunger pumps, centrifugal pumps could also be used. Fig. 8 shows the pre-tank as used in the installation shown in Fig. 7. The drawing shows the inlet chamber, the sludge chamber, weir chamber and the pump well from which the clarified sewage is lifted while the sludge gravitates to the ejectors.

Automatic Sewage Lifts and Water Power.—By use of the automatic sewage lift, sewage may be pumped by sewage,

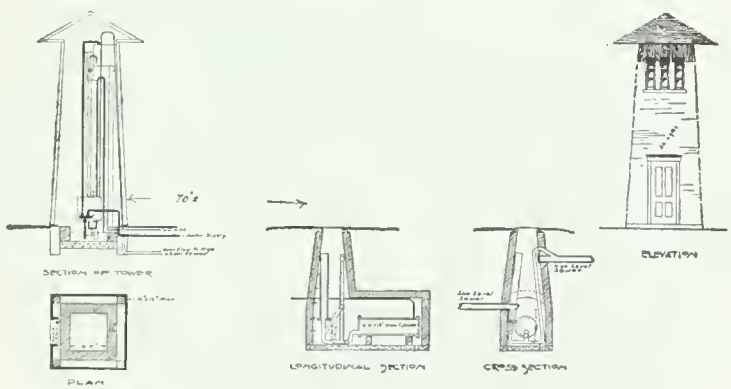

Fig. 11.

without cost, or else with the water power lift by water. As conditions do not always permit of the use of the lifts, they are not found so generally in service, but the entire absence of operating cost with these devices warrants their consideration under all circumstances.

The cost of a sewage system may be decreased by draining a low-lying district separately and lifting the sewage, thus avoiding deepening the excavation throughout the entire system. A pumping station may not be advisable owing to the cost of attendance of operation. In such cases a study should be made of the possibility of using the automatic sewage lift. Very often topographical conditions permit of using the power stored in high level sewage to compress air so that the low level sewage may in turn be lifted by using this compressed air furnished at no cost. The lift is entirely automatic and clogging is avoided by the flushing effect of successive discharges of sewage. A typical installation of an automatic sewage lift is shown in Fig. 9.

Instead of pumping the low level sewage by power derived from the fall of high level sewage, water from a nearby stream or city main may be used instead. Fig. 10 shows a sewage lift wherein the power is derived from damming a small stream and Fig. 11 shows a water power lift operating on city water

PLASTIC FIRE BRICKS.

Boiler-door arches and furnace linings in one solid piece are now said to be practicable, owing to an invention of plastic fire brick by the late Lester Betson. The brick is pounded into the shape desired. It is quite stiff, and will remain as placed, it is said, without the use of forms or molds, except for a simple temporary support in a door-opening or under an arch. It is then set by means of a slow fire in a short time. When it becomes very hard it may be put to immediate use.

It is claimed that the bricks are neutralized for expansion and contraction, so that they are not cracked or otherwise affected by sudden changes of temperature. Clinkers do not readily adhere to the surface, which is smooth and unbroken. As it fills all crevices, it should be gas and air-tight. The brick is being introduced into Canada by the Inland Sales Company, Limited, of Winnipeg.

The International Engineering Works, Limited, of Amherst, N.S., Canada, have recently opened three new offices in addition to their regular offices at Montreal, Toronto, etc. These representatives are George M. Taylor, 816 Burrards Street, Vancouver, B.C.; J. F. Tracey, 321 Edmonton Street, Winnipeg, Man., and Grodwards Company, Cobalt, Ont.

The experiments of British railway companies which are considering the adoption of wireless telegrapry for railway signalling, marks a new departure in the progress of wireless and in the advance of railway science. The Midland, and the London and Southwestern railway companies have experimented with the Prentice automatic system, a Canadian invention, based upon co-operation between electrical and mechanical devices on a traction engine. (See *The Canadian Engineer* for Sept. 18th, page 470.) The London and Southwestern has laid a high frequency wave wire on the centre track and a series of insulated wires beneath a locomotive to receive radiant energy worked from these.

A green light in the engine cab indicates that the line is clear, and when the section ahead is not clear a red light shows. An audible warning is given and the brakes are applied automatically. The Midland Railway is using an improved pattern of the Railophore system employed on German state railways, rendering the passing of set danger signals impossible. Four distinct signals in the engine cab are followed by automatic brake application.

COAST TO COAST.

Vancouver, B.C.—Plans are being prepared for $5,000,000 worth of new civic work in Vancouver for next year.

Moose Jaw, Sask.—Reliable authority is given for the announcement that a union station is assured for Moose Jaw, though its situation is yet undecided.

Vancouver, B.C.—The Trout Creek bridge, the highest railway trestle bridge in British Columbia, is now completed for traffic. It has been erected at a cost of $11,000, is about 250 feet high and almost of the same length.

Yorkton, Sask.—The C.N.R. has called off its men from further grading work at Yorkton, and the grade from Wroxton is almost completed, though there is no certainty as to the time when steel will have been laid to this centre.

Ottawa, Ont.—Expenditures by the Public Works Department last year aggregated $18,844,223, according to the annual report, now being issued. Of this amount, $10,177,831 was spent on harbors, including dredging, and $7,420,885 on public buildings.

Brantford, Ont.—The present source of supply for gas to Brantford is far from sufficient, and complaints are general in the city about the low pressure of gas. To relieve the situation, work on the trunk line from Tilbury field, which will supply St. Thomas, London, and Woodstock, is being rushed to completion, and it is expected that Brantford will be connected in January.

Victoria, B.C.—Work costing in the neighborhood of $30,000 has been completed on the roadbed of the Victoria and Sidney Railway. The roadbed has been re-ballasted practically from Victoria to its terminal at Sidney, the bridges have been rebuilt, and a new gasoline-electric car has been introduced which is giving satisfaction. The result is that the public are now furnished with a really first-class suburban service.

Selkirk, Man.—Many citizens were present on November 2nd to witness the turning on by Mayor Ross, of Selkirk, of the switch that put in motion the motors of the first large power installation of the Selkirk municipal electric light and power department, e.g., the planing mill, box and grain door factory of the Wm. Robinson Company. The municipality is selling its power at the 3 cent rate, with further reduction for large consumption.

Fort William, Ont.—The C.P.R. rocker bridge across the McKellar River between Islands One and Two at Fort William, has been completed and will be used to carry trains to the new $2,000,000 coal dock and to the new freight docks. The bridge has been erected at a cost of $200,000, will carry double railway tracks, and may be used to serve for extensions of the street railway to island terminals.

Montreal, Que.—Last spring low-lying river banks covered with mud and snow outlined the shore stretching from the Black Diamond line wharf past Sohmer Park to the foot of Papineau Avenue. Now along this section of shore has been constructed a rampart of new wharfage, the wharf from the Black Diamond line shed sloping up to a level with the high wharves approached from Commissioners Street; and from behind this rampart comes the sound of the rush of work on the foundations of the steel sheds, which will be erected doubtless on the new wharves next season.

Moncton, N.B.—The condition of Moncton streets has been the cause of much local dissatisfaction and criticism. The city has used for paving purposes wooden blocks, slag, and macadam; but the results have been unsatisfactory. This is partly due to the difficulties a new city always experiences in paving operations; for streets are being continually dug up for sewerage, gas, water, and other installations. Moncton has almost settled the question of good sidewalks; and the citizens are now feeling that the authorities should direct their efforts towards an efficient system of street paving.

Cornwall, Ont.—The contractor, Mr. G. R. Phillips, of Cornwall, has completed the new pier at the eastern entrance to the Cornwall Canal. The work has been going on for the past year and a half. The pier is 600 feet long, and the style of construction conforms with the usual style of such structures. The entrance has also been widened and will relieve the congestion of craft frequent at the foot of the canal. A pier somewhat similar was erected about two years ago above lock 17, and with the addition of this new pier, navigation at the eastern end of the Cornwall Canal will be rendered much more safe.

Victoria, B.C.—Of the four piers to be constructed near the Ogden Point breakwater, three are to be 800 feet in length, and one 1,000 feet. They will be capable of accommodating the largest vessels that will be used in the Pacific trade for many years to come. Three thousand and four hundred feet of dockage, which will be provided by the piers for which tenders have been invited, will be doubled when all four piers have been completed. The importance of this work to the local cities and to the province is magnified by the fact that all material to be used in the construction, stone and concrete, will be of local manufacture.

Grand Falls, N.B.—The installation of a modern electric light system has been completed at Grand Falls. When the light was turned on for the first time, out of 400 lamps, only one was found to be out of commission. In addition to the street lamps, many churches, public buildings and private have been lighted by the same system; and the town has erected a large concrete sub-station, and is employing an electric pump for the waterworks system, instead of steam pump, which was not sufficiently powerful. The power is being supplied by the Maine and New Brunswick Electrical Power Company, Limited, whose power-house is situated at Arooscook Falls.

Halifax, N.S.—At Halifax, a pier is being constructed which, when complete, will be the most modernly equipped for accommodating oceanic travel in the world. The work requires 1,818 concrete piers, the largest ever used for a like purpose; and these are being driven into the harbor bottom by the biggest pile-driver in the world. The whole pier will be 700 feet long by 235 feet wide, provided with the best possible railway accommodation; and the superstructure will be a two-story fireproof immigration building of solid concrete, 200 feet wide, and almost as long as the pier. When finished, Halifax will possess the most excellent of immigration facilities.

South Vancouver, B.C.—Plans for local improvements for South Vancouver, now before the Municipal Council, will when carried out make that city one of the most modern municipalities in the Dominion. By-laws for the construction of a municipal electric light and power plant and a municipal gas plant have been taken up and given readings. They are now awaiting the approval of the ratepayers. Petitions asking the council to refer the by-laws to the property-owners for a vote at the time of the municipal elections or sooner are being circulated and largely signed. If these petitions are signed by ten per cent. of the voters, the by-laws will be referred to the ratepayers in due course, and if they are passed steps will be taken at once to begin the construction of the plants.

Port Alberni, B.C.—The city of Port Alberni, the new city at the head of the Alberni Canal, now possesses in its new $120,000 waterworks system, one of the finest supplies of water in the Province, equal in clearness and purity, it is said, to the celebrated Capilano brand. The supply is brought from a dam at an elevation of 614 feet, situated

seven miles from the city, and which collects the water as it comes falling over the rocks from its glacial source above the Golden Eagle basin. The retaining wall, which is a solid, massive piece of work, is constructed of huge, cribbed logs, filled in between with rocks. The building of this wall was a long, costly operation, as owing to floods the work was arduous, and delay was occasioned by the half-built wall being swept away when a sudden flood, caused by heavy rains, undid in a night the labor of weeks. The wall was built up again and is substantial enough to resist any pressure that can be brought to bear upon it. The water enters the intake pipe through the latest system of cleaning and screening chambers, which collect all small debris which would have a tendency to enter the pipe. Five miles of 16-inch continuous wood stave pipe, discharging three and a half million gallons a day, and capable of providing for 25,000 people, convey the water to the city limits, after which 10 and 12-inch steel pipes are used through the main streets, smaller wire-wound pipe, tapping the mains, being used for laterals. The average pressure on the mains is 70 pounds to the square inch, thus allowing a good head for fire-fighting purposes.

PERSONAL.

STANLEY M. OBORN, A. M. Can. Soc. C.E., A. M. Inst. C.E., has resigned from the Toronto City Engineer's office and has begun practice as a consulting civil engineer and architect.

SIR ALEXANDER BINNIE, whose recommendations Ottawa is acting upon in connection with her water supply, has been asked by the city to assume the duties of chief engineer of the accepted Thirty-one Mile Lake proposal.

CHAS. MURPHY, general superintendent of the Canadian Pacific Railway Company, at Winnipeg, and formerly general master of transportation, and local superintendent at Toronto, will likely accept an appointment to the Dominion Railway Commission, to begin duties January 1st, 1914.

W. G. MILLER, Provincial Geologist and Inspector of Mines for Ontario, was entertained by a dinner in his honor at the Toronto Club recently, in recognition of his scientific accomplishments and the public service he is rendering to Canada in connection with his administration of Provincial duties respecting geology and mining.

J. G. McMILLAN, B.A. Sc., has been appointed Inspector of Mines for the Cobalt district, succeeding T. F. SUTHERLAND, who, as reported in our issue of June 26th, 1913, became Chief Inspector of Mines for Ontario on July 1st, succeeding E. T. CORKILL. Mr. McMillan returned recently from Hudson Bay, where he conducted harbor surveys for the Dominion Government. He is a graduate in mining of the University of Toronto.

OBITUARY.

The death occurred, recently, of Sir William Henry Preese, known in England as the "father of wireless telegraphy." He was in his 80th year. Sir William introduced both the telephone and talking machine into England and was the inventor of many patents connected with the telegraph and telephone. For several years he was engineer-in-chief and electrician to the British Post Office and was at one time president of the Institute of Civil Engineers.

The death is also reported of Alfred Russel Wallace, one of the leading British scientists, in his 91st year. During his life he made unusually large and valuable contributions to natural science and economics, and travelled in every part of the world in pursuit of his studies. He was a prominent authority on the land question and a strong advocate of land nationalization.

CANADIAN SOCIETY OF CIVIL ENGINEERS, OTTAWA BRANCH.

Mr. G. R. G. Conway, chief engineer of the British Columbia Electric Railway, addressed the Ottawa Branch recently, on the construction of the Coquitlam Dam. This work, which has just been completed, is of special interest to engineers from the fact that in the construction hydraulic process was used. By this process streams of water under great pressure are turned on the hillsides, washing out the stones, clay, etc., which flow through flumes to the place where the dam is under construction. This continual falling builds up the dam which is packed solid by the great weight of water coming over the falls into it. The water in this particular lake has been raised about 60 feet.

This work proved to be exceedingly expensive, as the water supply for New Westminster comes from the same lake, and for this fact the land which was to be flooded by the raising of the water had to be cleared of all vegetable matter that might contain microbes. The total cost of clearing the land was about $666,000. This was of particular interest to Ottawa engineers, because in raising the level of Thirty-One Mile Lake the ground to be flooded must also be cleared of all vegetable matter.

COMING MEETINGS.

UNITED STATES GOOD ROADS ASSOCIATION.—Convention will be held at St. Louis, Mo., November 10th to 15th. Secretary, J. A. Rountree, L021 Brown-Marx Building, Birmingham, Ala.

NATIONAL MUNICIPAL LEAGUE.—Annual Meeting will be held in Toronto, November 12th to 15th. Secretary, C. R. Woodruff, 705 North American Building, Philadelphia, Pa.

AMERICAN INSTITUTE OF ARCHITECTS.—Forty-seventh Annual Convention, to be held in New Orleans, La., December 2nd, 3rd and 4th.

AMERICAN SOCIETY OF REFRIGERATING ENGINEERS.—Annual Meeting will be held in New York, December 2nd to 5th. Secretary, W. H. Reed, 154 Nassau Street, New York City.

AMERICAN SOCIETY OF MECHANICAL ENGINEERS.—The Annual Meeting will be held in New York, December 2nd to 5th, 1913.

AMERICAN ROAD BUILDERS' ASSOCIATION.—Tenth Annual Convention to be held in First Regiment Armory Building, Philadelphia, Pa., December 9th to 12th. Secretary, E. L. Powers, 150 Nassau Street, New York, N.Y.

AMERICAN INSTITUTE OF CHEMICAL ENGINEERS.—Annual Meeting to be held in New York, December 10th to 13th. Secretary, C. D. Odsen, Polytechnic Institute, Brooklyn, N.Y.

AMERICAN SOCIETY OF AGRICULTURAL ENGINEERS.—Seventh Annual Convention will be held at Great Northern Hotel, Chicago, December 29th to 31st. Secretary, I. W. Dickerson, Urbana, Ill.

AMERICAN CONCRETE INSTITUTE.—Tenth Annual Convention to be held in Chicago, February 16th to 20th, 1914. Secretary, E. E. Krauss, Harrison Building, Philadelphia, Pa.

ORDERS OF THE RAILWAY COMMISSIONERS
OF CANADA

Each week on this page may be found summaries of orders passed by the Board of Railway Commissioners, to date. This will facilitate ready reference and easy filing. Copies of these orders may be secured from *The Canadian Engineer* for small fee.

20684—October 31—Authorizing C.N.O.R. to connect, temporarily, with G.T.R. near town of Pembroke, Ont.: Provided Co. (C.N.O.R.) bear and pay all expenses incurred in construction, maintenance and removal of said connection.

20685—November 3—Approving general plan showing crossing of G.T.R., and Muskrat River, and detail plans of substructure of proposed bridge.

20686—October 27—Refusing application of Port Hammond and District Improvement Association, Port Hammond, B.C., for order requiring C.P.R. to put into effect same or similar week-end fares from Port Hammond to coast cities as now in effect from Vancouver to Port Hammond.

20687—October 27—Authorizing Esquimalt and Nanaimo Ry. to cross track of Wellington Colliery Co., Limited, or Canadian Collieries (Dunsmuir), Limited at or near Trent River Ry. Co., construct safety switch at or near station 290 on line of Wellington Colliery Co., Limited, and station flag man at said crossing for purpose of flagging all trains over same. And directing each of said Cos. bear and pay half cost and expense of constructing and maintaining said crossing, and half cost and expense of constructing, maintaining and operating safety switch, and wages of said watchman.

20688—October 27—Authorizing Wellington Colliery Ry. Co., to cross Esquimalt and Nanaimo Ry. at mile 5.924, subject to certain conditions.

20689—October 30—Establishing collection and delivery limits of Canadian and Dominion Express Cos., in city of Owen Sound, Ont.

20690—October 29—Authorizing C.P.R. to construct spurs for Fort William Starch Co., Limited, Toronto, Ont., from a point on easterly limit of right of way of main line, Man. Div., in Lots 6 and 7, Con. D., Island No. 2, Fort William, Ont.

20691 October 29—Authorizing, pending installation half-interlocking plant, C.P.R. to operate trains over branch line, crossing C.N.R. adjoining Neebing Avenue, Fort William, subject to certain conditions.

20692—October 29—Authorizing C.P.R. to construct spur for Rutley Lumber Co., Limited, Regina, Sask.

20693—October 27—Approving location C.P.R. station at Oakshela, in N.W. ¼, Sec. 34-16-6, W. 2 M., at mileage 8.0 on Co.'s main line, Moose Jaw Subdivision.

20694—November 3—Authorizing C.P.R. to construct, subject to terms of proposed agreement, temporary spur for Carter Halls-Aldinger Co., Limited, Winnipeg, Man.

20695—October 30—Authorizing C.P.R. to open for traffic portion of double track from mileage 25.5 to 28.0, Broadview Subdivision, a distance of 2.5 miles.

20696—October 28—Authorizing C.P.R. to construct sidings for the Toronto Structural Steel Co., Limited, Toronto, Ont., from a point on existing siding track, within limits of right of way of Ry. Co., in Lot 8, Con. 5, Tp. York, in northwesterly direction across Oak Street, town of Weston, into premises of said Steel Co., in Lot 9, Con. 5, Tp. York, Co. York, Ont., at mileage 4.46, Ont. Division.

20697—October 30—Amending Order No. 19127, dated April 25th, 1913, to provide that authority to construct sidings and cross Gilkinson Street, Hamilton, Ont., granted under said order, be subject to certain conditions. That consent of city to said crossing be not taken as in any way prejudicing its position when question of grade separation arises. That time for construction and completion of work, limited by Order No. 19127, as amended by Order No. 19312, dated May 10, 1913, be extended for three months from date of this order.

20698—October 30—Extending, for a period of ninety (90) days from date of this order, time within which G.T.R. complete siding and spurs therefrom into premises of Toronto Structural Steel Co., Limited, on Lot 9, Con. 5, Tp. York.

20699—October 31—Approving plans and specifications of Bogart Drain, where same crosses G.T.R. on N. ½, Lot 9, Con. 4, Tp. of Elgin, Ontario.

20700—October 31—Approving station site and station of G.T.P. Ry. at Tyee, mileage 26.5, Prince Rupert East, in Lot 27, Rge. 5, Coast District, B.C.

20701—October 31—Amending Order No. 19215, dated May 6th, 1913, by adding clause "2" to provide for cost of maintaining subway over Thompson Road, Tp. Bertie, Co. Welland, Ont., as follows:—15 per cent. by Pere Marquette R.R. Co., 47½ per cent. by G.T.R., 30 per cent. by M.C.R., and 7½ per cent. by Tp. of Bertie.

20702—October 31—Authorizing G.T.R. to construct siding into premises of Gidley Boat Co., town of Penetanguishene, Ont.

20703—October 30—Amending Order No. 19759, dated July 4th, 1913, by striking out Sec. 2 and substituting therefor following:—"That consent of city to crossing be not taken as in any way prejudicing its position when question of grade separation, or any further protection that may be required at crossing, arises."

20704—October 30—Amending Order No. 19764, dated July 4th, 1913, by striking out Sec. 2 and substituting following:—"That consent of city to said crossing be not taken as in any way prejudicing its position when question of grade separation, or any further protection that may be required at crossing, arises."

20705—November 3—Approving location C.N.R. third-class station at Bengough, Sask.

20706—October 31—Approving revised location C.N.R. Greenway Branch through Secs. 2 and 3, Tp. 3, Rge. 23, W.P.M., Man., from mileage 78.95 to mileage 80.21.

20707—October 31—Approving location C.N.O.R. station grounds at Deseronto, Tp. Tyendinaga, Co. Hastings, Ont., at mileage 134 from East Don.

20708—October 31—Authorizing M.C.R.R. to construct siding, or coke track, into premises of the American Cyanamid Co., in Tp. Stamford, Co. Welland, Ont. And approving and authorizing clearances as shown on said plan. Ry. Co. to construct and complete said siding within three months from date of this order.

20709—November 3—Authorizing C.P.R. to construct spur from Haley's Station, Ont., into premises of Renfrew White Granite Co.

20710—November 4—Authorizing C.P.R. to construct spur into premises of McCormack Manufacturing Co., Limited, in Lot 9, Con. 1, Tp. London, Co. Middlesex, Ontario.

20711—October 28—Authorizing T., H. & B. Ry. to construct spur, with two branch lines or offsets therefrom, in city of Hamilton, Ont., to serve Canadian Westinghouse Co., Limited, subject to and upon certain conditions.

20712—November 3—Approving locations of C.N.O.R. station grounds, namely—At Alice, mileage 96.65 from Ottawa, and at Hiam, mileage 91.6 from Ottawa, Tp. Alice, Co. Renfrew.

20713—October 28—Authorizing C.N.R. to construct across eleven (11) highways on its Alsask Southeasterly Line, Sask.

20714—October 28—Approving C.N.R. location of Station at Chandler, Saskatchewan.

20715—November 4—Authorizing C.N.R. to construct across five (5) highways on its Calgary-Macleod Branch, Prov. Alta.

20716—November 3—Authorizing C.N.O.R. to take, for purpose of carrying out diversion approved by Order No.

19871, dated July 22nd, 1913, portion of Lot 22, Con. 9, Tp. Fitzroy, Co. Carleton, Ont., property of S. Reid, Learmouth.

20717—October 30—Approving revised location C.N.R. Maryfield Branch through Tps. 5 and 6, and Rgs. 25 to 29, W. 2 M., Sask., from mileage 194.82 to 224.58.

20718—November 3—Amending Order No. 20469, dated October 1st, 1913, by striking out words, "and no objection to the granting of the application having been filed by city of Winnipeg, although duly notified as appears by affidavit of service of notice of the application, filed," and substituting therefor words following, in recital to said Order, namely: "and reading the objection on behalf of the city of Winnipeg, filed."

20719—October 28—Approving location C.P.R. station at Outram, Sask.

20720—November 4—Authorizing, subject to terms and conditions contained in agreement, with exception of provision that spur be moved on demand of Municipality, C.N.R. to construct spur for P. Hrynczuk from a point on Oak Point Branch, near Roy (Pacific) Ave., Rural Mun. Rosser, across said Avenue and through Lots 26, 58 and 59, Block 8, Plan No. 774, property of P. Hrynczuk, to Ross Ave., Mun. Rosser, Man.

20721—November 3—Extending, until December 1st, 1913, time within which C.P.R. complete work of diverting Nine Mile Road, in Lots 6 and 7, Con. 9, Tp. South Gower, Co. Grenville, Ont.

20722—November 4—Authorizing C.P.R. to construct extension to existing siding for W. Booth Lumber Co., Limited, Toronto, Ont., on land lying westerly of right-of-way of Company's main line, Ont. Div., and northerly of road allowance between Cons. 1 and 2, Etobicoke, Ont., at West Mimico.

20723—November 4—Authorizing C.P.R. to construct spur for Steel Equipment Co., Limited, Ottawa, Ont., on part Lot 17, Town of Pembroke, Ont., at mileage 106.52 from Ottawa.

20724—November 4—Authorizing C.P.R. to open for traffic portion of its double track from Ernfold to mileage 70.0 on Swift Current Subdivision, Sask.

20725—October 29—Authorizing, subject to terms and conditions of resolution, C.P.R. to construct new double-track bridge at Napier St., Iberville, Que., mileage 19.5, Farnham Subdivision.

20726—November 4—Authorizing C.P.R. to construct, by means of grade crossing, two extra tracks across Deveber Ave., Mun. of Taber, Alta.

20727—November 4—Authorizing C.P.R. to construct Bridge No. 35.92, White River Sub. Div., Lake Superior Div., near Goldie, Ontario.

20728—October 29—Authorizing C.P.R. to construct Bridge No. 0.32 at Lorne St., city of Kamloops, B.C.

20729—October 29—Authorizing C.P.R. to construct, by means of grade crossings, its ballast pit spur across highways from mileage 0 to 3.05 of said ballast pit spur, at mileage 3 from Bassano, on Bassano Easterly Branch.

20730—October 29—Authorizing C.P.R. to construct, by means of grade crossing, its ballast pit spur aross highway between Sec. 19-6-11, and Sec. 24-6-12, W. 4 M. on Weyburn-Sterling Branch.

20731—October 28—Approving location C.P.R. station at Mara, B.C., in N.E. ¼ Sec. 8-20-8, W. 6 M.

20732—October 28—Authorizing, subject to terms of proposed agreement, Canadian Bridge Co., Limited, to construct foot-bridge and grade crossing over Pere Marquette R.R. at Walkerville.

20733—October 27—Authorizing C.P.R. to construct, at grade, extension to passing track across Boundary St., Didsbury, Alta.

20734—November 3—Authorizing C.P.R. to construct road diversion in Sec. 4-23-27, W. 3 M., Sask., on Swift Current Northwesterly Branch. To construct, by means of grade crossing, its Swift Current Northwesterly Branch Line across said diversion, at mileage 96.3 on said branch line from Swift Current.

20735—October 27—Authorizing V.V & E. Ry. & Nav. Co., and C.P.R. to operate their trains over crossing at Burrard Inlet, city of Vancouver, B.C., without their being brought to a stop.

20736—October 29—Authorizing Montreal Light, Heat and Power Co. to lay concrete water tunnel under C.P.R. in Municipality of Ville LaSalle, Que., on south side of Lachine Canal, opposite to Lot No. 1021.

20737—October 30—Authorizing G.T.P. Branch Lines Co. to construct spur for Union Coal Co., Limited, in Sec. 36-31-24, W. 4 M., Alta.

20738—October 29—Authorizing G.T.P. Ry., to construct spur turning out from its main line on 21st St. into Block 12, Inglewood Subdivision, city of Edmonton, Alta.; crossing of Brazeau Avenue, to be constructed in accordance with "Regulations."

20739—November 4—Directing that rating of 4th class provided in Canadian Freight Classification for blaugas and Carbonic Acid Gas be provided, also for oxygen and Acetylene gases in carloads. 2. Refusing application for a reduced less than carload rating of Oxygen gas.

20740—October 28—Authorizing C.P.R. to construct, subject to terms and conditions contained in agreement, by means of a bridge four tracks on its main line, Alta. Div., Lethbridge Sub. Div., over and across Westminster Road, Lethbridge, Alta.

20741—November 5—Authorizing C.N.R. to construct Bienfait-Estevan Branch over a coal mine, situated in S. ½, Sec. 19-2-6, W. 3 M., Saskatchewan.

20742—November 6—Directing that Pere Marquette R.R. Co., at its own expense, employ and maintain a watchman at crossing of highway 1¾ miles west of Kingsville, Ont., pending installation of bell at said crossing.

20743—November 5—Relieving North Shore line of C.P.R., from providing further protection at crossing of first public highway west of the west switch at Little St. Martin, Que.

20744—October 9—Relieving G.T.R. from providing further protection at crossing of public road one mile east of Wyoming, Ont.

20745—November 5—Approving locations C.P.R. stations at Tribune and Bromhead on Estevan-Forward Branch, Saskatchewan.

20746—November 6—Approving location C.P.R. station at Westerham, in S.E. ¼, Sec. 34-22-27, W. 3 M., Swift Current Northwesterly Branch, Province of Saskatchewan.

20747—November 5—Extending, until December 31st, 1913, time within which C.P.R. install electric bell, required under Order No. 20017, dated August 11th, 1913, at crossing of Main Street, village of Shelburne, Ontario.

20748—November 6—Authorizing C.P.R. and Quebec, Montreal and Southern Ry. Cos., to operate their trains over crossing at mileage 18.81 from Farnham, Que., without their first being brought to a stop.

20749—November 6—Extending, until November 30th, 1913, time within which C.P.R. install gates at crossing of Centre Street, Chatham, Ont., required under Order No. 19051, dated April 14, 1913.

20750—November 6—Authorizing C.P.R. to open for traffic portion of its Weyburn-Stirling Branch from mileage 0 to 49.2, east of Stirling, Alberta: Provided speed of trains be limited to a rate not exceeding 25 miles an hour.

20751—November 6—Authorizing C.P.R. to operate bridge crossing St. Lawrence River at mileage 41.9, Farnham Subdivision.

20752—November 6—Authorizing C.N.R. to construct across eleven (11) highways on its Alsask Southeasterly line, Sask.

20753—November 6—Authorizing C.P.R. to construct, for Godson Contracting Co., Limited, an extension to existing track and a passing siding track in Lot No. 16, Con. 10, Tp. Darlington, at mileage 53.43 on Ry. Co.'s main line, Ontario Division, Toronto Subdivision.

20754—November 7—Authorizing C.P.R. to construct Bridge No. 9.17 on Nipigon Subdivision, over Maggot River, Ont.; and rescinding Order No. 20084, dated August 18th, 1913, in so far as it authorizes construction of said bridge.

20755—November 6—Authorizing C.P.R. to construct spur for Kettle River Co., Minneapolis, Minn., from a point on existing spur in N.E. ¼, Sec. 8-11-4, E.P.M. at North Transcona, Manitoba.

20756—November 6—Authorizing G.T.R. to construct siding into premises of the Canada Stove and Furniture Co., on Lot 409-342, 259, 250, 264, parish St. Laurent, Quebec.

20757—November 6—Authorizing Galbraith and Sons, to construct tramlogging road under V.V and E.R. and Nav. Co.'s trestle bridge, No. 73, near Lincoln, B.C.

Barrett Specification Roofs

If you should specify merely "a five ply tar-and-gravel roof" instead of a "Barrett Specification Roof"—

You *might* get as good a roof as a Barrett Specification Roof though built somewhat differently—

But on the other hand, you may get materials of uncertain qualities,—

Or a roof with little or no pitch between the layers,—

Or a scanty surface coating of pitch and gravel—

And you wouldn't know about it until a few years later—*when the roof leaked*—

But if you put the Barrett Specification into your building specifications and see that it is carried out, you are sure—

1. That the materials will be right,
2. That they will be used in the right amount and in the right way,
3. That your roof will last upwards of twenty years without another cent of expenditure,
4. And that the cost per foot per year of service will be lower than it could possibly be with any other kind of roofing.

As Barrett Specification Roofs cost less than any other permanent roof to begin with and as their maintenance cost is nothing, the unit cost comes down to about ¼c. per square foot per year, a figure unapproached by any other roof covering.

Copy of the Barrett Specification with tracing ready for incorporation into your building plans, sent free on request. Address nearest office.

Special Note We advise incorporating in plans the full wording of The Barrett Specification, in order to avoid any misunderstanding. If any abbreviated form is desired however the following is suggested: ROOFING—Shall be a Barrett Specification Roof laid as directed in printed specification, revised August 15, 1911, using the materials specified, and subject to the inspection requirement.

RAILWAYS—STEAM AND ELECTRIC.

Calgary, Alta.—The by-law concerning the proposition of property owners to construct an extension of the street car lines into the Shaganappi park section, with a guarantee against deficits for four years, after which time the city were at liberty to operate the line or to allow it to stand idle, has met with defeat.

Hamilton, Ont.—City Engineer Macallum has reported to the city board of control upon the expenditure required to place the East End incline railway in a safe and workable condition. He recommended that four trenches be excavated across the incline; that two of these trenches be dug to a depth of three feet into dry clay, and that two be dug into the rock edge. The clay should be burned, forming a kind of brick, and four concrete walls should be placed across here, and side ditches should be made for drainage purposes. It was all a matter of drainage, said the engineer, and if that was satisfactory the land would not slide. The cost would be approximately $3,000. The work would necessitate 2,000 yards of excavation and 250 yards of concrete, and could be completed in about a month if a good gang of men was employed. Mr. G. F. Webb will report upon the action the railway company will take in this matter.

London, Ont.—Word has been received in London to the effect that the Grand Trunk Railway system must install at once and maintain a derail and interlocking system at the intersection of Dundas Street and the interswitching line.

Medicine Hat, Alta.—The city engineer has completed plans for the Esplanade subway, and these have been submitted to the city council together with an estimate of $84,753.42, including street costs for paving and sidewalks. The council, after examining the plans, were of the opinion that the plans should be submitted to the Railway Commission and the Canadian Pacific Railway, with a provision that the street improvements, including the sidewalks and paving, may at the wish of the city be accomplished at a later date. This will reduce the cost of the subway to $52,303.00 for the present. A motion to this effect was passed and the mayor and clerk authorized to sign the plans. The council also asked for an extension of six months in the time of completion of the subway, which will allow until July 27th to have the work finished.

Montreal, Que.—The city board of control is considering the Grand Trunk Viaduct problem. Mr. Geo. R. MacLeod, city traffic engineer, recommends that the city press for the improvement; and Mr. C. Laurendeau, city attorney, is asking for instructions as to the way the city should proceed with the case, allowing the urgency for the viaduct, but desiring to be instructed if the city will pay a share of the cost. Considering all estimates of the cost of the construction, both with and without damages, the approximate cost with damages may be placed at $5,500,000.

+—Ottawa, Ont.—The Cabinet council at its session of November 7th, let the contract for new switching signals for the Intercolonial Railway for $85,000 to the UNION SWITCH SIGNAL COMPANY of Montreal, Que.

Ottawa, Ont.—The Canadian Pacific Railway Company has given notice that it will apply to the Parliament of Canada, at its next session, for an act extending the time within which it may construct several railways; one from, at, or near Hawarden, to a point at or near Floral, or Cheviot, or a point between those places in the province of Saskatchewan; another, from, at, or near Sedgewick southerly to a point in township 39 or 40, Range 12 or 13, province of Alberta; a third, from a point on Will branch to a point near the North Saskatchewan River in township 51, Saskatchewan and Alberta; a fourth, from the northwesterly terminus of the Asquith branch to a point at or near Battleford, in the province of Saskatchewan; a fifth, from a point at or near Irricana to a point in township 20 or 21 in the province of Alberta; and, a sixth, from Killam to Strathcona, Alberta.

Ottawa, Ont.—At the next session of the Dominion Parliament, the Manitoba and Northwestern Railway Company will apply for an act extending the time within which it may construct the following lines of railway from Theodore to Junction with its Russell branch in township 20 or 21, Range 28; from Birtle to Hamiota; from Harrowby to Hamiota; from Russell to a point near Shoal River; from, at, or near Theodore to Junction with Pleasant Hills branch of the C.P.R. between Govan and Lanigan.

Ottawa, Ont.—Tenders will be received up till November 27th for 196,000 ties to be delivered at Hervey Junction and La Tuque, P.Q., in quantity and quality as specified. Plans and specifications may be obtained from Mr. Gordon Grant, Chief Engineer, Ottawa, Ont. Signed, P. E. Ryan, Secretary, Commissioners of the Transcontinental Railway.

Ottawa, Ont.—The Central Canada Railway Company have made application to parliament through their solicitors, Messrs. Pringle and Guthrie, for a charter with power to construct and operate a railway from Winnipeg to Edmonton, via Yorkton, Saskatoon, and Battleford.

70 % saving in joints

can be effected by using MANNESMANN TUBES, as they can be supplied in lengths up to forty feet. This means a reduction of from sixty to seventy per cent. in number of joints, jointing material and labor. Not only is actual money saved but safety is increased as there are proportionately fewer possible points of leakage. The total net cost of Mannesmann Tubes, when laid, is very low on account of the saving in joints and the speed with which the mains can be laid.

51 Victoria Square **Montreal** Limited

Ottawa, Ont.—A charter will be sought at the next session of parliament by the Ontario Lake Front Terminal Railway, which proposes to build a line from a point on the Canadian Pacific Railway, between Havelock and Central Ontario Junction, to Cobourg, by way of Campbellford, and from the latter town to Brighton.

Regina, Sask.—Mr. F. J. Robinson has presented to the council of the local Board of Trade a motion calling upon the city council to take some action to prevent any existing line or any new company from entering the city on these or any other lines, unless they be built adjoining those already constructed. The motion met with much discussion, but was referred finally to the committee on legislation.

Regina, Sask.—A by-law has been read authorizing the street railway to borrow a further $100,000 from the bank. This will mean that by the end of the year the city will have expended on street railway construction and equipment about $400,000.

St. Catharines, Ont.—The Grand Trunk Railway sheds have been completely destroyed at St. Catharines at an estimated loss of $50,000.

Toronto, Ont.—The Ontario Government has been requested by the Mayor and representatives of the municipality of Owen Sound to assist in securing for Owen Sound railway connection with Meaford. The G.T.R. will not agree to any proposal unless Government assistance is assured. The federal government has offered the usual subsidy of $6,400 per mile, and a further bonus from the province is being sought.

Toronto, Ont.—A branch civic line down Lansdowne Avenue to the C.P.R. crossing above Royce Avenue is being advocated by Works Commissioner Harris. It is estimated that this line would cost $104,186; and that operating and interest expenses would be about $17,078 per year.

Vancouver, B.C.—Reliable information has been received in Vancouver that New York capital has been raised for the completion of the Portland Canal and the North Eastern Railway.

+—Victoria, B.C.—The contract has been awarded to EVA''S, COLEMAN AND EVANS for the supply to the city of steel rails for the light railway to be built in connection with the Sooke waterworks. About 550 tons gross will be required.

Winnipeg, Man.—In view of the fact that both the city and C.N.R. Company objected to the application of the Winnipeg Sandstone Brick Company, Limited, for the construction of a C.N.R. spur track across Pembina Street to the company's premises, no order was issued by the Board of Railway Commissioners. It was decided that the engineer of the commission should make a report upon conditions.

Winnipeg, Man.—The C.N.R. will apply in the next few days for permission to double track their cut-off across Fort Rouge, after which the Board of Railway Commissioners will consider the application for a subway under the C.N.R. tracks at Pembina highway.

Winnipeg, Man.—The Board of Railway Commissioners, which met recently in Winnipeg, decided with reference to the C.P.R. spur line over Selkirk Avenue, that the order compelling its removal should be refused, but that an order should be issued compelling the company to raise the track to the level of the other tracks, which will, moreover, enable street car connection on the line to be made. The Board also instructed Mr. George Spencer, assistant chief operating officer of the company, to make a report on the smoke and noise nuisance; and for this he was given a month's time.

GARBAGE, SEWAGE AND WATER.

Hamilton, Ont.—According to Mayor Allan, the town of Dundas cannot be supplied with water from Hamilton without repumping halfway between the two municipalities. However, if the McKittrick survey came into the city, and got the water, the water could be conveyed by repumping to Dundas; since the city will have a surplus water supply to sell to outside concerns and municipalities.

Hull, Que.—The city of Hull is maintaining an attitude evasive rather than favorable towards assuming any financial responsibility in connection with the Ottawa water supply scheme, even to the extent of the water used by Hull. The feeling was voiced by Mayor Dupuis when he gave as a reason that in lieu of Ottawa's pipe line running through Hull and the province of Quebec, the city of Hull should not be called upon to contribute for its supply; moreover, that Hull is not anxious to depart from its present source of supply.

Lethbridge, Alta.—The announcement has been made by Mayor Hardie and Alderman Aird, chairman of the public works committee of the council, that over 7,000 feet of 6 and 8-inch water main will be laid in North Lethbridge this fall and winter at a cost of approximating $10,000. Practically all the waterworks extensions to be undertaken were passed upon by the 1912 council, but were not completed owing to the lack of money. The Bank of Montreal has met the city in its request for credit, and the work is now to be undertaken.

London, Ont.—The city council has passed a motion recommending and authorizing the Board of Works to commence work this winter, if at all possible, on the new storm-sewers, and also on extension and improvement in connection with the existing sanitary sewerage system.

Medicine Hat, Alta.—The tenders for the Medicine Hat unit of the waterworks system have been opened, and the city council has decided to call again for tenders for a 2,000 k.w. generator and a 1,500 k.w. generator in order to compare prices and to decide upon the better type to use.

Oshawa, Ont.—The Board of Water Commissioners met last Friday afternoon to consider tenders for a new electrically-driven centrifugal pump. The contract will likely be awarded to Canadian Allis-Chalmers, Limited, who were the lowest tenderers, but no definite action has yet been taken. It was decided by the Commissioners to issue $20,000 debentures to cover the cost of the pump and of other repairs and additions to the waterworks. A by-law covering this amount will be submitted to the citizens January 1st, unless council should care to pass the by-law by two-thirds vote, without submitting it to the people. Filtration is recommended by the Town Engineer, Mr. Chappell, but it is thought that the necessary money will not be available for a filtration plant for another year. Oshawa uses about 700,000 gallons daily at the season of maximum demand.

Ottawa, Ont.—Tenders will be received up till November 22nd, 1913, for a supply of hypochlorite of lime for the waterworks department of the city of Ottawa. Specifications may be obtained from the city bacteriologist, Slater Street, Ottawa, Ont. Signed, John Henderson, City Clerk, Ottawa.

Stratford, Ont.—The city council has passed the recommendation of the Board of Works calling for improvements at the sewage disposal plant.

LIGHT, HEAT AND POWER.

Bellingham, Ont.—Secretary Houston of the Department of Agriculture has issued a 50-year permit to the Skagit Power Company, a subsidiary of the Stone and Webster Company. The company will construct a power plant in the Upper Skagit River country, to cost $5,000,000 and to develop 27,610 horsepower. The waterpower is to originate in the Washington national forest reserve to the north and east of Marble Mount, and comprises rights on numerous tributaries of the Skagit.

Brandon, Man.—City Electrician Skead of Brandon has completed the installation of an interlocking plant to prevent accidents in that city at the point where the street railway and the Canadian Northern tracks cross. This plant is said to be the first of its kind installed in western Canada, and consists of two one-lever interlocking machines, equipped with electric locks and circuit controllers and two signal towers erected 300 feet on each side of the crossing on the C.N.R. line. These towers have the semaphores which give the signals to trains. It was stated that failure on the part of the trains to obey signals set for danger would result in derailment, and that any failure of the electric current would cause the signals to be set automatically to danger.

Calgary, Alta.—Tenders will be received up till December 31st, for certain machinery and equipment. Plans and specifications may be obtained from *The Canadian Engineer*, Winnipeg, Toronto, and Montreal; or from T. L. Turnbull, Esq., Consulting Engineer, 202 Eighth Avenue West, Calgary, Alta.

Davidson, Sask.—The Canada Gas Producer Company of Barrie, Ont., has submitted a proposal to the town council of Davidson, by which the company will install an 80 horse-

COVENTRY
Noiseless Chains

are rapidly supplanting belting and spur gearing for every form of power transmission because of their proved superiority. They eliminate the vexatious delays due to broken belts and spur wheel teeth. They run unaffected by moisture and heat which would make belts useless. They give positive ratio between driver and driven, and automatically adjust themselves to pinion wear. They so reduce friction and slip that **they transmit power at a standard efficiency of 98 per cent.**

Can you afford to do without COVENTRY Noiseless Chains? *Write for full information.*

power 3-cylinder engine, including all necessary equipment for $8,500, to be paid only on satisfactory test after installation. A by-law is to be submitted to ratepayers on December 8th.

Dundas, Ont.—The treasurer of the Town Council has been ordered to issue a corporation cheque of $2,110 in accordance with the arbitration award in the town acquiring the Dundas electric light plant. Concerning the lighting of the square occupied by the new postoffice building, the government's proposal to erect an ample number of light standards on the postoffice property, the light to be furnished by the town, was satisfactory, and was accepted.

London, Ont.—The Hydro-Electric Commission of Ontario and the London Street Railway have signed the agreement by which the company will purchase from the commission during the life of the company's franchise, which will expire in 12 years, 1,000 horsepower of direct current electricity at $36 per horsepower. The railway will be supplied with the power from December 15th.

Ottawa, Ont.—Tenders will be received up till November 20th, 1913, for electric wiring and fittings for public building, Port Colborne, Ont. Plans and specifications may be obtained from the Department of Public Works, Ottawa, Ont. R. C. Desrochers, Secretary.

Peterboro, Ont.—The city council has passed a by-law authorizing the appointment of Mr. Robert A. Ross of Montreal as arbitrator to act for the city in proceedings between the city and the Peterboro Light and Power Company.

Peterboro, Ont.—The Power Committee of the city council is ready and willing to concede the control and operation of the Hydro system to the Peterboro Water Commissioners, and the city council has passed a resolution inviting the latter to confer with the proper authorities with a view to arranging an agreement.

+—Souris, Man.—The contract has been awarded the BRANDON MACHINE AND IMPLEMENT WORKS by the municipality of Souris for the supply of lampposts for the new lighting system, at an estimate of several thousand dollars

Victoria, B.C.—At a large meeting of the voters of Ward Six, South Saanich Municipality held recently, the following resolution was passed unanimously:—"That in view of the increasing needs of the wards adjoining the city of Victoria, they are undertaking to mortgage the credit of the rural wards who can receive no benefits therefrom, and knowing, that ultimately Wards One and Two must be included in the city of Victoria, we, the ratepayers of Ward Six, present at this meeting, are most emphatically opposed to the raising of money for sewage purposes."

Winnipeg, Man.—Among eight by-laws to be brought before the ratepayers of the city on December 12th, is one to provide $1,000,000 for power distribution.

Winnipeg, Man.—Tenders will be received up till November 19th, 1913, for the electric wiring of the addition to the Hospital for Insane, Selkirk, Man. Plans and specifications may be obtained from the Provincial Architect, 261 Fort Street, Winnipeg, Man. Signed, W. H. Montague, Minister of Public Works, Manitoba.

Yorkton, Sask.—Tenders will be received up till December 22nd, 1913, for the supply and delivery of one 500 b.h.p. combined unit. Plans and specifications may be obtained from M. M. Inglis, Electrical Engineer, Yorkton, Sask Signed, T. F. Acheson, Secretary-Treasurer.

BRIDGES, ROADS AND PAVEMENTS.

Edmonton, Alta.—The Board of Railway Commissioners has decided not to grant the request of the city to construct a highway across the G.T.P. for the purpose of extending Vermilion Avenue across the railway. This decision effectually opens the way for the city's claims for subways and permanent protective measures at all railway crossings.

Edmundston, N.B.—Engineers have completed the final survey for an international steel bridge, which is to be erected across the Madawaska River next summer.

Hamilton, Ont.—The works department have in hand a big program of improvements to be executed next year. The principal item is connected with roadways. The idea now is to charge all such work on the local improvement plan, and do away with the fund of $50,000 of $60,000 now kept for stone roads and other highways not of a permanent nature. Some of this money will have to be put aside for repairs, but there will be a big saving. Instead of paying all the costs of certain work the city will only have to foot about forty per cent. of the bill. It is also planned to give every street in the city that will not stand flushing one sprinkling of oil during next summer, to be followed by the distribution of stone screenings.

Montreal, Que.—The first Canadian Good Roads Congress will be in session at Montreal for a week in January, 1914. Delegates will be present from the leading local Road Association, Board of Trade, Municipal, Provincial and Federal Governments, the Automobile Club of Canada, and various other societies interested in obtaining good roads throughout the country. Also, in connection with the congress, there will be an exhibition of road building materials.

Ottawa, Ont.—A sub-committee from the Street Railway Extension Committee has been appointed to meet a delegation of residents of Ottawa East to discuss the matter of the best site for the proposed new bridge across the canal. After meeting the citizen's committee, this sub-committee will report directly to the Board of Control.

St. Catharines, Ont.—The city council has reserved its decision to change the figure in the C.N.R. bonus by-law from $100,000 with a provision for vehicular and foot traffic, to $75,000 to provide for a high level railway bridge alone across the canal between locks and the present low bridge of the N.S. and T.R. Port Dalhousie line. The ratepayers will decide by vote whether the railway bridge providing for vehicles and foot passengers will be constructed.

Stratford, Ont.—The city council has passed the recommendations in the report of the Board of Works for the preparation of plans for the covering of Erie Creek, and for the opening of William Street.

St. John, N.B.—A petition which is to be presented to Premier Flemming, has been circulated, and is a protest against the construction of a bridge across the St. John River in connection with the Valley Railroad, the contention being that it will interfere with navigation on the river by logs and rafts. The petitioners, however, will be strongly opposed by those acting in the best interests of the Valley Railroad. And, in addition, it is understood that a movement is on foot among automobile owners to ask the Government that the bridge be made a highway as well as a railroad bridge.

Toronto, Ont.—A conference will be held on the morning of November 11, between the York Township Council and the Good Roads Commission regarding the repairing of the Don Mills road.

Toronto, Ont.—Tenders will be received up till November 18th, 1913, for the construction of asphalt, bitulithic and concrete pavements, and of gradings and sewers. Plans and specifications may be obtained from the office of the Commissioner of Works, Toronto. Signed, H. C. Hocken (Mayor), Chairman, Board of Control.

Toronto, Ont.—The revised proposal for the widening of the north part of Yonge Street has been approved by the civic Works Committee, and it is expected that the city council will authorize a by-law for the improvement. The plan is to widen the street on the east side from Collier Street to Lawton Avenue and Heath Street, and thence on the west side to the city limits at Bedford Park. The Street Improvement Committee estimate that this change of plan will involve a reduction of about a million dollars in the original estimated cost of $3,100,000.

Toronto, Ont.—Tenders will be received up till November 15th, for the construction of bitulithic pavement on Russell Hill road, in the Township of York. Plans and specifications may be obtained from the office of Frank Barber, Esq., C.E., Township Engineer, 57 Adelaide Street East, Toronto.

Toronto, Ont.—Tenders will be received up till November 15th, for the construction of concrete sidewalk on Baby Point Crescent, in the Township of York. Plans and specifications may be obtained from Frank Barber, Esq., C.E., Township Engineer, 57 Adelaide Street East, Toronto.

Vancouver, B.C.—Tenders submitted to the civic waterworks committee upon the two routes for the Point Grey partnership pipe by Beach Avenue and Granville Street bridge, and by Smythe Street and Connaught bridge, have shown differences in favor of the Point Grey engineers. Only on

the work of crossing False Creek does the Connaught bridge route appear to be cheaper. Before awarding contracts, the waterworks committee has requested the city engineer and Messrs. Cleveland and Cameron, Point Grey's advisory engineers, each to submit a report on the tenders, after considering which the committee will take action.

Victoria, B.C.—It is announced that the contract for the construction of the Taghun bridge calls for its completion by March 31st. The material is due to arrive on the ground within the next few days and the arrangements have been made to have the requisite steel forward d as soon as ordered. The contractors have every reason to carry forward the work rapidly in their own interests as in the event of it not being finished before the spring floods ensue there is danger of the false work being carried away, thus involving additional expense.

Winnipeg, Man.—Alderman McLennan and Mr. James Eames have urged upon the city Board of Control that the city take some action looking to the construction of a subway at Talbot Avenue and that it notify the Dominion Railway Commission to that effect; since the Commission has given notice that it will order that the crossing be protected with gates if the city does not decide to build a subway at that point within two weeks. Mr Eames urged that the construction of the subway be undertaken as soon as possible and argued that if the gates were put up they might be allowed to remain there for many years, much to the injury of the community. The cost of the subway at Talbot Avenue is estimated at $188,000. The board will not make a recommendation on the subject until the matter has been discussed with the Public Utilities Commissioner.

INDUSTRIAL WORKS.

Lindsay, Ont.—It is understood that the government is arranging to widen the canal allowance, and to this end Engineer Spence and his assistants have taken the soundings of the river at Bobcaygeon from the dam to the mouth of the river on lines across the river, 50 feet apart, and sounding every 10 feet in those lines.

Montreal, Que.—The Montreal Board of Trade is once more taking up the question of the Georgian Bay Canal, and has drafted and adopted the following resolution to be forwarded to Mr. Borden and Mr. Cochrane:—"That the construction of the Georgian Bay Canal, long advocated by the Montreal Board of Trade as being of vital importance to Canada, is now deemed specially necessary by the council of the board in view of the increasing diversion by the Canadian to American channels of the carriage of Canadian grain for export. That understanding the Government has under consideration the appointment of a commission to enquire into the commercial feasibility of that canal and deeming the composition of such a board most important, the council hereby prays the Government to permit the commercial organizations of Montreal to make recommendations for appointment thereon."

Montreal, Que.—In the report of harbor improvements recently submitted to the Chambre de Commerce by Adelard Fortier, president of that body, Lieutenant-Colonel Labelle, is quoted as stating that development of the port of Montreal will be conducted on the north shore of the river and that the present Board of Harbor Commissioners have no intention of undertaking a programme for the construction of wharves on the south shore opposite the city.

New Westminster, B.C.—Mayor Gray has received communication from Ottawa informing him that the Hon. Dr. Roche, Minister of the Interior, has signed the agreement between the city and the Vancouver Power Company in final settlement of the Coquitlam Dam controversy.

+—Ottawa, Ont.—The contract has been awarded the firm of CHAMBERS, McCAFFREY AND McGUGAN for the construction of Nassau dam on the Trent Canal for $72,768.

Ottawa, Ont.—Tenders will be received up till December 3rd, 1913, for the construction of a breakwater at Little Sands, P.E.I. Plans and specifications may be obtained from the Department of Public Works, Ottawa, Ont. Signed, R. C. Desrochers, Secretary.

Ottawa, Ont.—Tenders will be received up till December 4th, 1913, for the construction of an extension to wharf at Gull Harbor, Lake Winnipeg, Man. Plans and specifications may be obtained from the Department of Public Works, Ottawa, Ont. R. C. Desrochers, Secretary.

Ottawa, Ont.—Tenders will be received up till December 4th for the construction of an extension to wharf at Gull Harbor, Lake Winnipeg, Man. Plans and specifications may be obtained from the Department of Public Works, Ottawa, Ontario. R. C. Desrochers, Secretary.

+—St. John, N.B.—The contract has been awarded D. C. CLARK for repairs to the wharf damaged by the SS. Wabana, at a cost of $1,600.

MISCELLANEOUS.

London, Ont.—The present equipment of the London incinerator is proving insufficient; and in the opinion of Superintendent W. C. Dodd, either the equipment will have to be increased shortly or a new plant will have to be built.

Medicine Hat, Alta.—The elevator of the Ogilvie Milling Company, with a capacity of 30,000 bushels, and containing at the time 12,000 bushels was burned recently; the engine house alone was saved.

▲—Ottawa, Ont.—Tenders will be received up till January 7th, 1914, for the construction of six 200-ton mechanical coaling plants with sandhouses complete to be erected at points on the National Transcontinental Railway. Plans and specifications may be obtained from Mr. W. J. Press, Mechanical Engineer, Ottawa, Ont. Signed, P. E. Ryan, Esq., Secretary of the Commissioners of the Transcontinental Railway, Ottawa.

Ottawa, Ont.—Ten tenders for plans have been received for the new proposed Government-owned elevator to be built at Port Nelson. The tenders have all been sent West to be considered by the Grain Commission.

Ottawa, Ont.—Armstrong, Whitworth and Company, the great British shipbuilding, contracting, and steel manufacturing firm, has been federally incorporated with stock of $2,000,000, and headquarters at Montreal. The new Canadian company is empowered to carry on a general shipbuilding, and iron and steel manufacturing business to build locomotives, automobiles, drydocks, terminals, etc.; and should war vessels be built in Canada, this company will be ready to offer tenders.

Ottawa, Ont.—While in Ottawa, a member of the firm of Barnett and McQueen, expressed himself as of the opinion that there are hopes of once more restoring to their original perpendicular the great concrete tanks of the Canadian Pacific Railway elevator at Transcona. At present, these are lying tilted at an angle of 45 degrees, one side having sank under the tremendous weight of wheat contained. However, due to the strength of reinforced concrete, the tanks have remained intact, and with the application of some herculean modern engineering force, they may be restored to the perpendicular. The proposed method is to excavate under the sunken side, powerful jacks being used to keep the structure up while the foundation is being strengthened. When this has been effected, the tanks will be allowed to sink back onto the flat surface. The leaning side will have to be heavily propped during the excavation process to prevent further listing, and to keep it in place. This work is estimated at a cost of $30,000.

Ottawa, Ont.—The Winnipeg River Power Company, Limited, with a capital stock of one million dollars and chief place of business in the city of Winnipeg, has been granted incorporation by the Department of State. Presumably this is the company which recently obtained extensive power rights at Great Falls, on the Winnipeg River.

Ottawa, Ont.—In his lecture on *The Work of the Dominion Observatory*, Dr. W. F. King stated that the big telescope to be erected by the Government may possibly be built elsewhere than in Ottawa. Owing to extreme changes in temperature, the large proportion of cloudy days and nights and other causes; and owing to the fact that this instrument will cost a very large sum of money, and the authorities naturally desire to get the most they can out of it, it will possibly be set up in the West, where atmospheric conditions are better for observation.

Regina, Sask.—An application for franchise in the city has been made by Calgary capitalists in connection with a gas scheme in many ways similar to the Georgeson scheme

A Combination in the Interest of Trade

Combinations in business are all right when they make for greater efficiency and better service to the public.

Our business is a combination of many businesses, or special lines, into a great "Departmental House for Mechanical Goods." We find by organizing our business along departmental lines that we can serve industrial Canada more efficiently, more economically and in a way that makes for the best interests of our customers.

You will find it a great convenience to deal with a House that can supply you practically anything you require in the mechanical line all "under one roof." One of the two items mentioned below may interest you

Elwell-Parker Electric Trucks

Wherever used have shown an actual saving of from 25 to 65 per cent., both for railroads and industrial concerns. One large Canadian plant trying electric trucks for the first time claims that each truck, operated by one man, has replaced eight men with eight wheelbarrows.

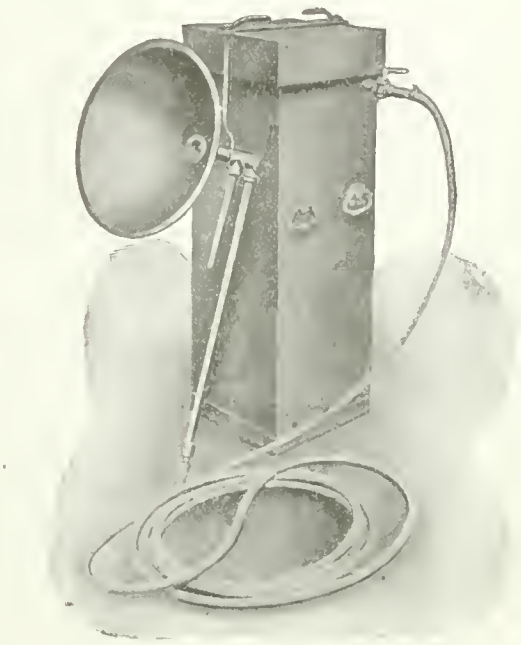
The truck shown above is one of the many types of Elwell-Parker Electric Storage Battery Trucks used by the American Express Co. The Canadian Pacific also use these trucks.

Elwell-Parker Electric Trucks are equipped with Edison Storage Batteries which are now recognized to be about the best on the market. Edison Batteries increase greatly the efficiency of the electric truck. We think so much of them that we would not advise you to purchase any electric truck that was not equipped with Edison Batteries.

Ellwell-Parker Trucks are extremely easy of operation, in no way requiring skilled labor, and by having a spare battery set can be worked continuously without injury

If you are extending or rebuilding your plant it will pay you to investigate this well known truck.

Ask for Bulletin 107.



The Milburn Light

The No. 3-W Milburn Acetylene Light shown here gives from 5,000 to 12,000 candle power and lights 1,500 feet. The light follows the crane or shovel and throws its rays directly on the work. It lights instantly, requires no attention, and positively defies wind and weather. Has water tight cover and is made to withstand hard usage, the vibration and movement of cranes, steam shovels and dredges. Supplied with 15 inch aluminum reflector and 25 feet of armoured hose with connections. Cost 4 to 6 cents per hour to operate. Over 70,000 Milburn lights have been sold.

Ask for catalogue of Milburn Lights.

offered about a year ago. The details concerning the contract offered by the present company are not made public, though the scheme is to pipe gas from the southern Alberta fields to Regina and other cities.

+—Vancouver, B.C.—The PALMER SHIPBUILDING COMPANY, Jarrow, has been awarded a contract for the construction of a large new steamer for the Ellerman Line, Liverpool.

+—Vancouver, B.C.—The NEWPORT NEWS SHIPBUILDING COMPANY has been awarded the contract by the Standard Oil Company for the building of an oil tanker, 640 feet long, 29 feet deep, and of 60-foot beam; equipped with oil-burning engines capable of making a speed of 10½ knots; and costing, when complete, $1,000,000.

+—Vancouver, B.C.—The contract has been awarded MESSRS. WILLIAM GRAY AND COMPANY, West Hartlepool, by Norwegian owners, for an oil tank steamer to be built on the Isherwood system of construction.

CURRENT NEWS.

Calgary, Alta.—In the opinion of Mr. R. L. Walker, as stated in the Calgary News-Telegram, the C.P.R. Company must have its Bassano dam completed, tested, and filled with water before freeze-up, in order to have its irrigation system to the south of the province in operation next year.

Fort William, Ont.—The superintendent of construction has stated that the incinerator plant being built by Mr. M. H. Braden, contractor, situated near the Neebing River between the Fort William road and the C.N.R. tracks, will be in use by the city within the next two weeks. Upon a long incline reaching from the ground to the top of the building, steel rails have been laid which connect with the electric steel railway, and specially constructed dump cars will be used to gather the garbage from all over the city and to carry it to the incinerator. When the dump cars reach the roof of the building, the contents are dumped through trap doors set between the rails, directly on big concrete slabs where it is quickly dried by the heat from the furnaces. It is then automatically shot into the furnaces where it is entirely consumed in the short space of three or four minutes. A tall brick smoke stack, 85 feet in height, has been built to carry off the smoke and gases arising from the burning refuse. Mr. M. H. Braden stated this morning that the building would cost when completed in the neighborhood of $22,000.

New Westminster, B.C.—Dredging the bar at the mouth of the Pitt River will begin within a few days, when the Pacific Dredging Company, who have secured the contract, will put their big suction dredge, Robson, at work, with its attendant outfit. Arrangements have been made by the company for depositing the material dredged on the lower end of Douglas Island. A channel 300 feet wide and 15 feet deep at low water will be dredged by the removal of nearly two million yards of silt and sand.

Ottawa, Ont.—It is stated that trains will be operated this winter on practically the whole stretch of the N.T.R. from Cochrane to Moncton. Now that steel has been laid, contractors' trains, which have been serving the mills and colonists, both east and west of Cochrane, and also between Quebec and the New Brunswick boundary, will be of service to the public, on both of these sections of the line, and to improve the condition of the track.

Ottawa, Ont.—The latest report concerning the progress of the N.T.R. from Moncton to Winnipeg is that this gap has been lined up save for the completion of the bridge over the second branch of the Megiskan River. The bridge is due to be finished by this time, and is at a point directly north of Ottawa. When the rails are laid over this bridge the whole line, except the Quebec bridge, will be connected not only throughout the eastern division, but also from coast to coast, save for 200 miles on the Grand Trunk Pacific section in British Columbia. Up to date the eastern section has cost $165,000,000 inclusive of shops and roundhouses.

Sunderland, B.C.—Messrs. Bartram and Sons, Sunderland, have completed a shelter-deck steamer, with a deadweight carrying capacity of about 8,000 tons, equipped with engines of 26-inch, 43-inch, 67-inch, and 48-inch stroke, and with three single-ended boilers. It has been sold and will be delivered in December to the Royal Mail Steam Packet Company, London, Eng.

Toronto, Ont.—Excellent progress is reported upon the construction of the Central Technical School Building, Toronto. The excavation work has been entirely completed, and two of the largest size concrete mixers are working continuously on the heavy concrete work around the boiler house section. The Dominion Bridge Company has commenced the erection of steel, and Messrs. Ross and Macdonald, the architects, report that 450 tons of steel have been delivered. The masonry has been once more begun at the north end of the building; the superintendent of the Keystone Fireproofing Company is making preparation for the laying of floors; the brick work alone being held back by the slow delivery of material.

PATENTS.

The following is a list of patents recently issued through the agency of Messrs. Ridout and Maybee, 59 Yonge Street, Toronto, from whom further particulars may be obtained:—

Canada.—Bernard Hausheer, can-manipulating machines; Bernard Hausheer, cap-soldering machines; Bernard Hausheer, solder-placing machines; Thos. D. Kelly, flexible compositions; Olof Soderlund, evaporation, distillation and similar operations; Alfred C. Clayton, water heaters; John F. Staley, safety mechanism for the winding gear of coal pits and the like. Ernest R. Lee, valve tools; Erich Ebler, processes for preparation, isolation and enrichment of radium and other radio-active substances; Albert C. Gee, rail joints; Horace H. C. Sintzenich, rail joints; Walter Broadbridge and A. L. Howard, apparatus for ore concentration; H. H. Greenway and A. H. P. Lowry, ore concentration.

United States.—James R. Calder, railway rails; Sidney E. Trout, connecting means for locomotive pilots and foot boards.

MONTREAL MARKET LETTER

Montreal, November 8th.

The local iron and steel trade is feeling somewhat more cheerful insofar as relates to particular companies, but in the matter of the general position it may be doubted if the situation has improved. The situation as respects the financing of the Dominion Steel Corporation is not quite so depressing. The financial statement for the second quarter of the fiscal year of the company is all that could be asked for, showing, as it did, an increase for the half year of half a million dollars in the matter of net earnings, as compared with the first half of the previous year, and holding out a prospect that the year might, under similar conditions, wind up with a million increase. Also, it is reported that the financing negotiations in London are making good progress and that it will not be necessary to pass the dividend on the common stock. So far as the other large basis iron and steel industry, the Nova Scotia Steel and Coal Company, is concerned, the publication of the October output has produced a most favorable impression, the company having broken all previous records in respect to steel production.

In spite of the above, it is recognized that the future is uncertain. Car companies and other large industries are still operating regularly, but the activity is due to contracts placed some time ago, rather than to those placed of late. It is admitted without question that there has been a falling off in orders as compared with a year ago and the prospects are at the moment that the works will not be so busily employed during the coming year. Nevertheless, the feeling is that enough business will be forthcoming before long to ensure the operation of the plants for some time to come.

The depressing influence seems to be coming from outside in large part. From Germany and England come advices of a falling-off in industrial activity and from nearer at hand—the United States—is the report that prices are falling lower and lower and that railways are not placing their orders. The question which is still agitating the trade here, is the extent to which this will eventually affect the Canadian market. The answer must wait on time. Meantime, prices hold steady.

The fire call

need not be a serious matter if your building is properly protected —or, better still, if it is also properly designed from the standpoint of fireproofness.

Whether the building that you contemplate erecting, or are erecting, is a little garage or a big six-story factory, it will pay you to make it as fireproof as possible. To do so does not necessarily mean extra expenditure. The cost of the improvements in design or equipment that we might be able to suggest would likely be fully balanced by the lower insurance rates that we could then obtain for the structure.

We desire to act without charge as consulting engineers — specializing on "fireprnofness" — to any architects, owners or engineers. Make use of our services.

Concrete Costs

By FREDERICK W. TAYLOR, M.E., Sc.D., and SANFORD E. THOMPSON, S.B., Mem. Amer. Soc.C.E. Small 8vo, xxii+709 pages, 82 figures. Cloth, $5.00 net.

Tables and recommendations for estimating the time and cost of labor operations in concrete construction and for introducing economical methods of management.
The costs in this work are made up from actual practice and experiences in every case. Entirely different from any other book ever published on this subject.

SECOND EDITION, Revised and Enlarged

Concrete, Plain and Reinforced

By FREDERICK W. TAYLOR and SANFORD E. THOMPSON. 8vo, xli+821 pages, 249 figures. Cloth, $5.00.

In this edition is included the developments in the design and construction of reinforced concrete since the issue of the first edition.

SECOND EDITION, Revised and Enlarged

Principles of Reinforced Concrete Construction

By F. E. TURNEAURE, Dean of the College of Engineering, and E. R. MAURER, Professor of Mechanics, University of Wisconsin. 8vo, x+429 pages, 17 plates and 164 figures. Cloth, $3.50.

Covers in a systematic manner, those principles of mechanics underlying the design of reinforced concrete.

TENTH EDITION

A Treatise on Masonry Construction

By IRA OSBORN BAKER, B.S., C.E., D. Eng'g., Professor of Civil Engineering, University of Illinois. 8vo, xv+745 pages, over 100 tables and 244 illustrations. Cloth, $5.00.

NINTH EDITION, Re-written

TOTAL ISSUE—14,000

The Theory and Practice of Modern Framed Structures

JOHNSON—BRYAN—TURNEAURE

In three parts. Part I—STRESSES IN SIMPLE STRUCTURE. 8vo, xii+326 pages, illustrated with cuts throughout the text. Cloth $3.00 net. Part II—STATICALLY INDETERMINATE STRUCTURES AND SECONDARY STRESSES. 8vo, xvi+538 pages, 313 figures. Cloth, $4.00 net. Part III—DESIGN. (In preparation).

TENDERS CALLED FOR

Sealed tenders addressed to the undersigned and endorsed "Tender for Wharf and Warehouse at Richard's Landing, Ont.," will be received at this office until 4 p.m., on Tuesday, December 2, 1913, for the construction of a Wharf and Warehouse at Richard's Landing, St. Joseph Island, Algoma District, Ontario.

Plans, specification and form of contract can be seen and forms of tender obtained at this Department and at the District Engineer's offices, Sault Ste. Marie, Ont.; Confederation Life Building, Toronto, Ont., and on application to the Postmaster at Richard's Landing, Ont.

Persons tendering are notified that tenders will not be considered unless made on the printed forms supplied, and signed with their actual signatures, stating their occupations and places of residence. In the case of firms, the actual signature, the nature of the occupation and place of residence of each member of the firm must be given.

Each tender must be accompanied by an accepted cheque on a chartered bank, payable to the order of the Honorable the Minister of Public Works, equal to ten per cent. (10 p. c.) of the amount of the tender, which will be forfeited if the person tendering decline to enter into a contract when called upon to do so or fail to complete the work contracted for. If the tender be not accepted the cheque will be returned.

The Department does not bind itself to accept the lowest or any tender.

By Order,

R. C. DESROCHERS,
Secretary.

Department of Public Works,
Ottawa, October 31, 1913.

Newspapers will not be paid for this advertisement if they insert it without authority from the Department.—48268.

DEPARTMENT OF RAILWAYS AND CANALS, CANADA.

CANADIAN GOVERNMENT RAILWAYS.

HALIFAX OCEAN TERMINALS RAILWAY, HALIFAX, N.S.

CALL FOR NEW TENDERS.

Sealed tenders addressed to the undersigned and endorsed "Tender for Docks, First Unit, Contract No. 3," will be received at this office until 12 o'clock noon, Thursday, November 20, 1913, for the construction of about 6,500 lineal feet of quay wall, foundations for buildings, sewers, dredging of harbor to a depth of 45 feet at low water and filling reclaimed areas.

Plans and specifications and form of tender may be seen and full information obtained at the office of the General Manager, Moncton, N.B., at the office of the Chief Engineer of the Department of Railways and Canals, Ottawa, and at the office of the Superintending Engineer, Halifax, N.S.

The right is reserved to reject any or all tenders.

By Order.

L. K. JONES,
Assistant Deputy Minister and Secretary.

Department of Railways and Canals,
Ottawa, 30th October, 1913.

Newspapers inserting this advertisement without authority from the Department will not be paid for it.—50200.

Sealed tenders addressed to the undersigned, and marked on the envelope "Tender for 200-ton Mechanical Coaling Plants with Sandhouses," will be received at the office of the Commissioners of the Transcontinental Railway at Ottawa, Ontario, until 12 o'clock noon of the 7th day of January, 1914, for the construction and erection complete, in accordance with the plans and specifications of the Commissioners of six 200-ton Mechanical Coaling Plants with Sandhouses complete, to be erected at the following points on the line of the National Transcontinental Railway as set forth below, viz:—

One at Monk, P.Q.	Mile	385.2
One at Bridge, P.Q.	"	460.6
One at Fitzpatrick, P.Q.	"	588.2
One at Parent, P.Q.	"	705.3
One at Doucet, P.Q.	"	806.4
One at O'Brien, P.Q.	"	915.4

Plans may be seen and forms of tender and specifications obtained at the office of Mr. W. J. Press, Mechanical Engineer, Ottawa, Ontario, and at the offices of Mr. A. E. Doucet, District Engineer, Quebec, and Mr. T. S. Armstrong, District Engineer, Cochrane, Ont.

Persons tendering are notified that tenders must be made on the printed forms supplied by the Commissioners, and that each tender must be signed and sealed by all the parties to the tender, and witnessed, and be accompanied by an accepted cheque on a Chartered Bank of the Dominion of Canada, payable to the order of the Commissioners of the Transcontinental Railway, for a sum equal to five per cent. (5 per cent.) of the amount of the tender.

The cheque deposited by the party whose tender is accepted will be deposited to the credit of the Receiver-General of Canada as security for the due and faithful performance of the contract according to its terms. Cheques deposited by parties whose tenders are rejected, will be returned within ten days after the signing of the contract.

The right is reserved to reject any or all tenders.

By Order,

P. E. RYAN,
Secretary.

The Commissioners of the Transcontinental Railway.
Dated at Ottawa, Ont., November 3rd, 1913.

Newspapers inserting this advertisement without authority from the Commissioners, will be not paid for it.—50357.

TOWN OF YORKTON, SASKATCHEWAN.

TENDERS FOR DIESEL ELECTRIC MACHINERY.

Sealed tenders marked "Tenders for Diesel Electric Machinery," addressed to T. F. Acheson, Secretary-Treasurer, Town of Yorkton, Sask., will be received up to 12 o'clock, Monday, 22nd December, 1913, for the supply and delivery of one 500 b.h.p. combined unit. Specifications and all information may be obtained upon application to M. M. Inglis, Electrical Engineer, Yorkton. The lowest tender not necessarily accepted and the right is reserved to reject any or all tenders.

T. F. ACHESON,
Secretary-Treasurer.

(For further Tenders see page 88.)

TRANSPORTATION BUILDING — MONTREAL

TENDERS CALLED FOR

TENDERS FOR IRON POSTS.

Sealed tenders addressed to the undersigned and endorsed "Tenders for Iron Posts," will be received at the Department of the Interior, up to noon of the 1st day of December, 1913, for the furnishing of fifteen thousand small and five hundred large iron posts for use on the survey of Dominion Lands, to be delivered at Edmonton on or before the 31st day of January, 1914.

Forms of tender and detailed information may be obtained from the Surveyor-General of Dominion Lands, Ottawa.

The tender must be accompanied by an accepted cheque on a chartered Canadian bank for the sum of two hundred dollars, payable to the order of the Deputy Minister of the Interior. This cheque will be forfeited if the party whose tender is accepted declines to enter into a contract to deliver the posts or fails to carry out the contract. If the tender is not accepted the cheque will be returned.

The Department does not bind itself to accept the lowest or any tender.

Newspapers copying this advertisement without authority from the Department will not be paid.

L. PEREIRA,
Secretary.

Department of the Interior,
Ottawa, October 31st, 1913.

TENDERS FOR MACHINERY AND EQUIPMENT.

Tenders will be received by the Bowness Improvement Company at their offices, 202 Eighth Avenue West, Calgary, Alberta, until 5 p.m., December 31, 1913, for the following machinery and equipment:—

"L." One 200 k.w. Traction Motor Generator.

"M." One four panel Switch Board.

"N." One 250 k.v.a. Generator.

"O." One Vertical Single Acting Multi-Cylinder Gas Engine.

Bidders must enclose certified cheque in the amount of 5 per cent. of their tenders. Cheques of unsuccessful tenderers will be returned immediately after contracts are awarded. Specifications may be obtained from the engineer, and may be seen in the offices of *The Canadian Engineer*, 820 Union Bank Building, Winnipeg, 62 Church Street, Toronto and 628 Transportation Building, Montreal.

The lowest or any tender not necessarily accepted.

T. L. TURNBULL,
Consulting Engineer,
202 Eighth Avenue West,
Calgary, Alberta.

TENDERS FOR BITULITHIC PAVEMENT.

Sealed Tenders plainly marked as to contents will be received at the office of the undersigned, up to **Noon of Saturday, November 15th, 1913,** for the construction of Bitulithic Pavement on Russell Hill Road in the Township of York.

Plans, specifications and all necessary information may be seen at the office of Frank Barber, C.E., 57 Adelaide Street East, Toronto.

The lowest or any tender not necessarily accepted.

FRANK BARBER,
Township Engineer.

Toronto, November 11th, 1913.

DEPARTMENT OF RAILWAYS AND CANALS, CANADA.

WELLAND SHIP CANAL.

SECTION No. 5.

NOTICE TO CONTRACTORS.

Sealed Tenders, addressed to the undersigned and marked "Tender for Section No. 5, Welland Ship Canal," will be received at this office until 12 o'clock noon on **Tuesday, November 18th, 1913.**

Plans, specifications and form of contract to be entered into can be seen on or after this date at the office of the Chief Engineer of the Department of Railways and Canals, Ottawa, and at the office of the Engineer in Charge, St. Catharines, Ontario.

Copies of plans and specifications may be obtained from the Department on the payment of the sum of fifty dollars. To bona fide tenderers this amount will be refunded upon the return of the above in good condition.

Parties tendering will be required to accept the fair wages schedule prepared or to be prepared by the Department of Labor, which schedule will form part of the contract.

Contractors are requested to bear in mind that tenders will not be considered unless made strictly in accordance with the printed forms, and in the case of firms, unless there are attached the actual signature, the nature of the occupation, and place of residence of each member of the firm.

An accepted bank cheque on a chartered bank of Canada for the sum of $100,000.00 made payable to the order of the Minister of Railways and Canals, must accompany each tender, which sum will be forfeited if the party tendering declines entering into contract for the work, at the rates stated in the offer submitted.

The cheque thus sent in will be returned to the respective contractors whose tenders are not accepted.

The cheque of the successful tenderer will be held as security, or part security, for the due fulfilment of the contract to be entered into.

The lowest or any tender not necessarily accepted.

By order,
L. K. JONES,
Assistant Deputy Minister and Secretary.

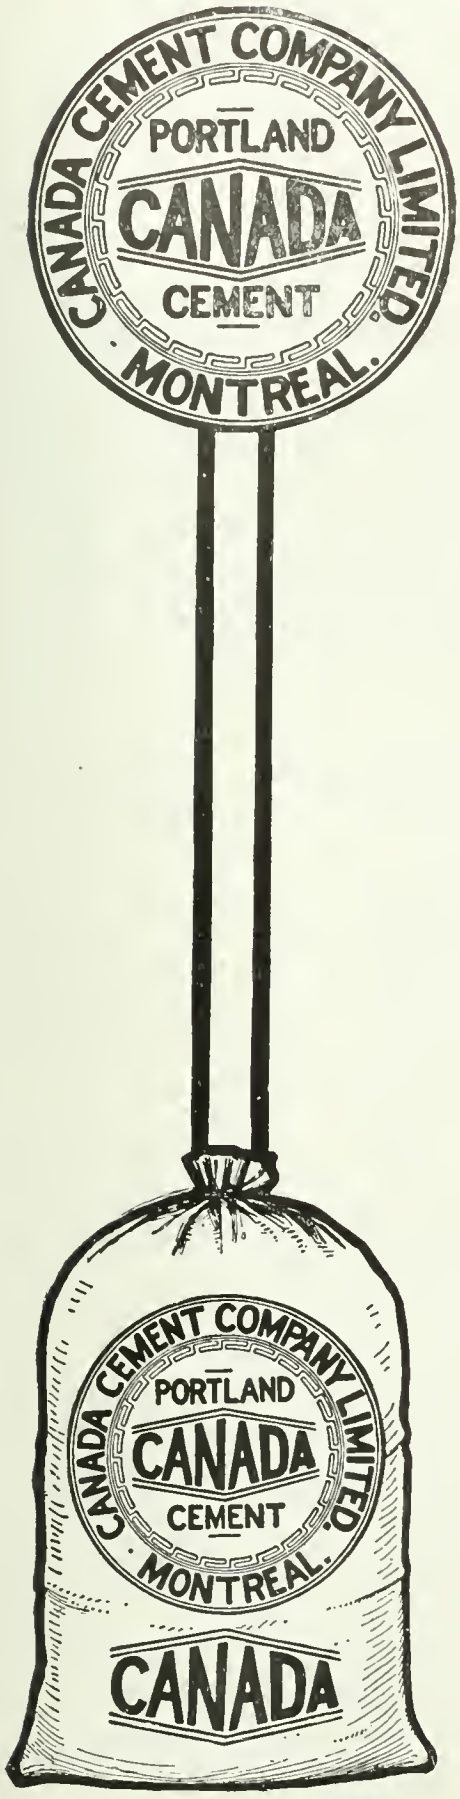
Department of Railways and Canals,
Ottawa, 29th October, 1913.

Newspapers inserting this advertisement without authority from the Department will not be paid for it.—50010.

(For further Tenders see page 86.)

MUNICIPAL OFFICIALS ARE INVITED TO FILE PLANS AND SPECIFICATIONS OF PROJECTED WORK AT ANY OF THE **CANADIAN ENGINEER** OFFICES — IT WILL BE FOUND A CONVENIENCE TO CONTRACTORS AND WILL RESULT IN MORE AND BETTER BIDS BEING SUBMITTED

PERMANENCE—



an ideal that is now attainable

THE superiority of concrete over all other materials for the building of permanent structures is now generally admitted.

The next step towards ideal construction, is to realize that for satisfactory concrete work, it is necessary to use a cement that is uniformly high-grade

CANADA Portland CEMENT

is the selection of the leading engineers, architects and contractors. Their experience has proved that in this brand they can obtain a certainty of success.

With concrete coming into more and more general use for the construction of buildings, bridges, viaducts and highways, it is vitally important that those in authority on such matters should select the best materials obtainable.

Use the cement that our best architects and engineers have selected for their most important undertakings. Select Canada Cement — it costs no more than any others.

Contractors' Machinery For Sale Or Rent

We have in stock the following second-hand equipment for immediate delivery.

Get further details and prices.

1 - 7" x 10" double cylinder, double drum steam hoist
1—6½" x 8" double cylinder, single drum steam hoist.
1—No. 2 Ransome concrete mixer.
1—No. 3 Ransome concrete mixer.
5—6 ft. Ransome concrete carts.
1—8"x 10"x 8" steam driven air compressor.
1—6" x 5" x 7" steam driven air compressor.
1—6" belt driven centrifugal pump.
1—5" belt driven centrifugal pump.
1—15 H.P. semi-portable boiler on skids.

H. W PETRIE, LIMITED
General Machinery Dealers. TORONTO, Ont.

FOR SALE.—One 35 h.p. gas engine, in good condition, suitable for city or natural gas. Apply Box 1505, General Post Office, Winnipeg.

WANTED.—Duplex Steam Pump, size 17 by 10 by 12. Slight variation in dimensions not detrimental. J. L. Millard, Aylmer, Ontario.

Positions Vacant

Advertisements under this heading two cents per word per insertion. Minimum charge fifty cents per insertion.

WANTED.—Assistant Engineers, Transitmen, Levellers, Rodmen, Chainmen, Inspectors and Draftsmen for all branches of engineering work. We make no charge to enroll you on our books. Send for application form. Civil Engineer's Employment Bureau, P.O. Box 62 Station "B.," Montreal.

CHIEF ENGINEER.—An excellent opportunity offered to an experienced engineer to connect with an established Consulting Engineering and Construction Corporation, based on co-operative plan; offices in Cleveland, Detroit, Buffalo and New York City. The position requires a man to take complete charge of the mechanical and electrical departments. Highest references and $1,500 investment required. Contract with salary, commission and expenses guaranteed. Address Box 174, *The Canadian Engineer*, Toronto.

Positions Wanted

Advertisements under this heading one cent per word per insertion. Minimum charge fifty cents per insertion.

STENOGRAPHER.—Experienced in engineering correspondence, estimating and accounting, desires position, preferably as secretary. Gilt-edged references. Please address, Box 168, *The Canadian Engineer*, Toronto.

ENGINEER—Long experience in erecting and running steam and electrical installations of high capacity (in charge), desires position in the above, or as master mechanic. Technical knowledge. Just finished construction work. All round and skilful. Highest references. Box 176, *Canadian Engineer*, Toronto.

Condensed Advts.

IN THE MATTER of Canadian Re-Issue Letters Patent 147,858, dated November 7th, 1911, and issued to William Arthur Bone, James William Wilson and Cyril Douglas McCourt, for steam generation, feed water heating and the heating of liquids generally. Take notice that the Invincible Renovator Manufacturing Company, Limited, of 81 Peter Street, Toronto, Ontario, Canada, have commenced manufacture of apparatus for the purpose of steam generation, feed water heating and the heating of liquids generally, covered by said letters patent, and are prepared to supply any demand for the same at a reasonable price. Ridout and Maybee, 59 Yonge Street, Toronto, attorneys for Bone, Wilson and McCourt.

PATENT NOTICE.—Any one desiring to obtain the invention covered by Canadian Patents Nos. 90234 and 90235 granted on November 29th, 1904, to William A. Lawrence, of New York, U.S.A., for rubber extraction, may do so upon application to the undersigned, who are prepared to supply all reasonable demands on the part of the public for the invention and from whom full information may be obtained. Fetherstonhaugh and Smart, Castle Building, 53 Queen Street, Ottawa; Russel S. Smart, resident.

FOR SALE OR LEASE United States and Canadian Patents Nos. 872073 and 107427 respectively for improvements in the design of filters for water supply, or sewage disposal, the principal of which has been favorably commented upon by the technical press of both continents, and is being gradually and inadvertently imitated in the design of modern works. Particulars on application to the Proprietor, Box 248, Red Deer, Alberta, Canada.

NEW INCORPORATIONS.

Coleman, Alta.—Pelletier Lumber Company, Limited, $100,000.

MARKET CONDITIONS

Montreal, November 10th, 1913.

Bar Iron and Steel—Trade is reported active. Bar iron, $2.05 per 100 pounds; best refined horseshoe, $2.30; forged iron, $2.20; mild steel, $2.15; sleigh shoe steel, $2.15 for 1 x ⅜ base; tire steel, $2.25 for 1 x ⅜ base; toe caulk steel $3; machine steel, iron finish, $2.25.

Cement—Canadian cement is quotable, as follows, in car lots, f.o.b., Montreal:—$1.35 to $1.40 per 350-lb. bbl., in cotton bags, adding 10c. for each bag. Good bags re purchased at 10c. each. Paper bags cost 2½ cents extra, or 10c. per bbl. weight.

Chain—The market is quoted per 100 lbs. as follows:—¼-in., $5.65; 5/16-in. $4.70; ⅜-in., $4.00; 7/16-in., $3.65; ½-in., $3.45; 9/16-in., $3.45; ⅝-in., $3.35; ¾-in., $3.25; ⅞-in., $3.15; 1-in., $3.05.

Explosives and Accessories—Dynamite, 50-lb. cases, 40 per cent. proof, 15c. in single case lots, Montreal; 50 per cent., 16½c., and 60 per cent., 18c. Blasting powder, 25 lb. kegs, A, $1.85, and B, $2.35 per keg. Special quotations on large lots of dynamite and powder. Detonator caps, case lots, containing 5,000, 75c. per 100; double strength, $1, and broken lots higher; electric blasting apparatus:—Batteries, 1 to 10 holes, $13.50; 1 to 10 holes, $20.50; 1 to 50 holes, $41. Wire, leading, 1c. per foot; connecting, 50c. per lb. Fuses, platinum, single strength, per 100 fuses:—4-ft. wires, $3; double strength, $3.50; 6-ft. wires, $3.54, and double, $4.04; 8-ft. wires, $4.08, and double, $4.58; 10-ft. wires, $5, and double, $5.12.

Galvanized Iron—The market is steady. Prices, basis, 28-gauge, are:—Queen's Head, $4.40; Colborne Crown, $4.20; Apollo, 10¾ oz., $4 30. Add 25c. per 100 lbs. to above figures for less than case lots; 26-gauge is 25c. less than 28-gauge, American 28-gauge and English 26 are equivalents, as are American 10¾ oz., and English 28-gauge.

Galvanized Pipe—(See Pipe, Wrought and Galvanized)

Iron.—Following prices are on dock. No. 1 Summerlee, $21.75 per ton; selected Summerlee, $21.25; soft Summerlee, $20.75 per ton. No. 3 Middlesboro irons are about $19 per ton. Carron iron number for number and grade for grade is quoted about the same price as Summerlee. Canadian iron sells here at about $19 to $19.50 per ton, on track.

Lath—See Lumber, etc.

Lumber, etc.—Prices on lumber are for car lots, to contractors, at mill points. Red pine, mill culls out, $20 to $22 per 1,000 feet; white pine, mill culls, $20. Spruce, 1-in. by 4-in. to 6-in., $21; 1 x 7 to 9, $24 per 1,000 ft.; mill culls, $18. Hemlock log run, culls out, $19. Railway Ties, Standard Railway Ties, hemlock or cedar, 50 to 55c. each. Telegraph poles: seven-inch top, cedar poles, 25-ft. poles, $2, each; 30 ft., $3.75; 35-ft., $4.50 each; 40-ft., $6; 45 to 50, 16c. per foot. Laths: Quotations per 1,000 laths, at manufacturers' points. Spruce 4-ft. x 1½ in., mill run, $3 to $3.25; pine 4-ft. x 1⅜-in., mill run, $3.25 to $3.75. Shingles: Cedar shingles, same conditions, as laths, X, $2 10; XX, $2.40; XXX, $2.80.

Pipe—Cast Iron—The market is dull and rather easy:—$34 for 6 and 8-inch pipe and larger; $35 for 40-inch at the foundry. Pipe, specials, $3 per 100 pounds. Gas pipe is quoted at about $1 more than the above.

Pipe—Wrought and Galvanized—Demand is fair and the market steady: —¼-inch $5.50, with 63 per cent. off for black, and 48 per cent. off for galvanized; ⅜-inch, $5.50, with 63 per cent. off for black, and 48 per cent. off for galvanized; ½-inch, $8 50, with 69 per cent off for black, and 59 per cent. off for galvanized. The discount on the following is 72½ per cent. off for black, and 62½ per cent. off for galvanized: ¾-inch, $11.50; 1-inch, $16.50; 1¼-inch, $22 50; 1½-inch, $27. On the following the discount is 72½ per cent. for black and 62½ per cent. for galvanized:—2-inch, $36; 2½-inch, $57 50, and 3-inch $75.50; 72½ per cent. off for black, and 62½ per cent. off for galvanized: 3½-inch $95 4-inch, $1.08.

Toronto, November 12th, 1913.

The following are the wholesale prices for Toronto, where not otherwise explained, although for broken quantities higher prices are quoted:

Axes.—Standard makes, double bitted, $6 to $10; single bitted, per dozen, $7.50 to $9.

Bar Iron—$2.25 base, per 100 lbs., from stock to wholesale dealer. In enormous demand.

Bar Mild Steel—Per 100 lbs., $2.25. Sleigh shoe and other take same relative advance.

Boiler Plates—½-inch and heavier, $2.20. Boiler heads 25c. per 100 pounds advance on plate. Tank plate, 3-16-inch, $2.40 per 100 pounds.

Boiler Tubes—Orders continue active. Lap-welded, steel, 1¼-inch, 10c. 1½-inch, 9c. per 10-ft.; 2-inch $8.50 to $9; 2¼-inch, $10; 2½-inch, $10.50; 3-inch $12.10; 3½-inch, $15; 4-inch, $19.

Bricks—In active movement. The price is $11.50 for grey stock, $12 for red stock. Don Valley pressed brick are in request. No. 1 dry pressed and buff bricks are worth $18 delivered and $17 at works per 1,000. Port Credit Brick Company's prices are as follows, f.o.b., Port Credit: Wire cut bricks, $10 per M.; pressed bricks, $13 to $15 per M., three grades.

Broken Stone—Lime stone, good hard, for roadways or concrete, f.o.b., quarries 70 to 75c per ton of 2,000 lbs., either 1-inch, 10c., 2-inch, or larger, price all the same. Rubble stone, 55c. per ton, Schaw station, and a good deal moving. Broken granite is selling at $3 per ton for good Oshawa, or Quebec Province. At Washago, $2.50 per ton for small, and $1.15 for large, freight to Toronto 60 cents.

Cement—Demand very brisk, and prices maintained. In large quantities the price is $1.50, sacks, 40c. extra; car lots $1.55, sacks extra; city dealers ask $1.85, sacks extra. Prices remain firm.

Copper Ingot—The market is lower at 15½ to 16c., sheet copper case (16 oz. soft), 22½c. to 24½c. per lb.

Detonator Caps—75c. and $1 per 100; case lots, 5,000, 20 per cent. off.

Dynamite—The prices for this explosive vary according to the percentage of nitro-glycerine compounded in the mixture and are as follows, f.o.b., Toronto:—40 per cent., 16¼ cents per pound, 1 to 9-case lots, 50 lbs. to case. For each additional 10 per cent. nitro-glycerine add 1½c. per hundred. For 10-case lots and over deduct ½ cent. For 20-case lots and over deduct 1 cent. For 40-case lots and over deduct 1½ cents.

Fuses—Electric Blasting—Double strength, $3.50 per hundred, advance 54c. per hundred for each 2-in. wire additional. Single strength, $3 per hundred, advance 54c. per hundred for each 2-in. wire additional.

Iron Chain—¼-inch, $5.75; 5-16-inch, $5.15; ⅜-inch, $4.15; 7-16-inch, $3.95; ½-inch, $3.75; 9-16-inch, $3.70; 5-8-inch, $3 55; ¾-inch, $3.45; ⅞-inch, $3.40; 1-inch, $3.40 per 100 lbs.

Iron Pipe—Quotations are changed as follows:—Black pipe, ¼-inch, $2.04; ⅜-inch, $2.04; ½-inch, $2.72; ¾-inch, $3.16; 1-inch, $4.54; 1¼-inch $6.19; 1½-inch, $7.43; 2-inch, $9.90; 2½-inch, $15.60; 3-inch, $20.75; 3½-inch, $26.13; 4-inch, $29.70; 5-inch, $40 60; 6-inch, $52.64. Galvanized Pipe, ¼-inch, $2.86; ⅜-inch, $2.86; ½-inch, $3.57; ¾-inch, $4.31; 1-inch, $6.19; 1¼-inch, $8.44; 1½-inch, $10.13; 2-inch, $13.50; 2½-inch, $21.56; 3-inch, $28.31.

Lead—Firmer, $5.25 to $5.50.

Pig Iron—We quote Clarence at $24 for No. 3; Cleveland, $24; Summerlee, $27; Hamilton quotes $22; Midland, No. 1, $22; No. 2, $21.50. There is considerable enquiry for 1912.

Pitch and Tar—Pitch, unchanged at 75c. per 100 lbs. Coal tar, $3.75 per barrel.

Roofing Slate—Most of the slate used in Canada comes from Pennsylvania or Maine, the Canadian supply being slender and mostly from the Rockland quarries of the Eastern Townships in Quebec. There is a great variety of sizes and qualities, so that it is difficult to indicate prices. But Jackson Bangor, 10 x 16 may be quoted at $6.75 per square of 100 square feet f.o.b. cars, Toronto; seconds, 50c. less. Mottled, $8; green $8, with a prospect of advance. Dealers are fairly busy.

Sand—Sharp, for cement or brick work, $1.15 per net yard f.o.b., cars, Toronto siding.

Sewer Pipe—

	4-in.	6-in.	9-in.	12-in.	24-in.
Straight pipe; per foot	$0 25	$0.40	$0.65	$1.00	$ 3.25
Single junction, 1 or 2 ft. long	1.00	1.60	2.60	4.00	13.00
Double junctions	1.25	2.00	3.25	5.00	16-25
Increasers and reducers	....	1.60	2.60	4.00	13.00
P. & H. traps	2.00	3.20	6.50	15.00	....
Bends	0.75	1.20	1.95	3.00	9.75

Above is the October list as changed. The retail price is less 65 per cent. off these figures on all sizes 9 inches and under, or less 60 per cent. off these figures on anything over 9 inches. For car-loads a greater discount.

Steel Beams and Channels—Active—We quote:—$2.65 to $3 cut to length per 100 lbs., according to size and quantity; angles, 1½ by 3-16 and larger, $2.50 to $2.75; tees, $2 75 to $3 per 100 lbs. Extra for smaller sizes of angles and tees.

Sheet Copper—22c. per lb.

Sheet Steel—American Bessemer, 10-gauge, $2.75; 12-gauge, $2.80; 14-gauge, $2.50; 17, 18, and 20-gauge, $2.75; 22 and 24-gauge, $2.80; 26-gauge, $2.85; 28-gauge, $3. A very active movement is reported at unchanged prices.

Sheets, Galvanized—Apollo Brand—Sheets, 6 or 8 feet long, 30 or 36 inches wide: 10-gauge, $3; 12-14-gauge, $3; 16, 18, 20, $3.30; 22-24, $3.40; 26, $3.50; 28, $3.90; 29, $4.10; 10¾, $4.10 per 100 lbs. Fleur de Lis—28-gauge, $4.25; 26, $4.05 per 100 lbs. Active and firm at these prices.

Tin—The combination seems to hold, and the price, 45 to 50c., lower.

Tool Steel—Jowett's special pink label, 10½c. Cammel-Laird, 16c. "H.R.D." high speed tool steel, 65c.

Tank Plates—3-16 inch, $2.40 per 100 lbs.

Zinc—Spelter—Good demand, and the feeling strong. Light stock; excellent demand. We quote very firm at $6 to $6.50 per cwt.

Winnipeg, November 11th, 1913.

Anvils—Per pound, 11½ to 12½c.; Buckworth anvils, 80 lbs. and up, 10¼ to 10¾c., anvil and vise combined, each $5.50.

Bar Iron—$2.50 base.

Bars—Crow $4.50 per 100 pounds.

Beams and Channels—$3 to $3.10 per 100 up to 15-inch, 4, 30, 41, 50, 118, 119, 172, 132, 145, 176.

Brick—Kiln run per M, $13; sewer pipe per M, $14; chimney per M, $14; veneer per M, $15; pressed per M, $25 to $50; enameled per M, $100; sand lime per M, $13.

Cement, Portland—$2.40 to $2.50 per barrel.

Chain—Coil, 3-16-in., $10; ¼, $7.25; 5-16, $5.85; ⅜, $5; 7.16, $4.75; ½, $4.50; 9-16, $4.50 ⅝, $4.40; ¾, $4.25. Logging, 5-16, 6½c.; ⅜, 5¾c. Tie out, 70 and 10 per cent.

Copper—Tinned, boiler, 26½c., planished, 29½c.; boiler and T. K. pits, plain, tinned, 45 per cent. discount.

Dynamite—$11 to $13 per case.

Galvanized Iron—Apollo, 10¾, $4.80; 28, $4.60; 26, $4.20; 22, $4.10; 24, $4.10; 20 $4; 18 $3.95; 16, $3.90. Queen's Head, 28, $4.90; 26, $4.70; 24, $4.30 22, $4.30; 20, $4.10 per cw

Iron—Swedish iron, 100 lbs., $4.75 base; sheet, black, 14 to 22 gauge, $3.75; 24-gauge, $3.90; 26-gauge, $4; 28-gauge, $4.10. Galvanized—American 18 to 20 gauge, $4.40; 22 to 24-gauge, $4.65; 26 gauge, $4.65; 28-gauge, $4.90; 30-gauge, $5.15 per 100 lbs. Queen's Head, 22 to 24-gauge, $4.65; 26-gauge English, or 30-gauge American, $4.90; 30-gauge American $5.15; Fleur de Lis 22 to 24-gauge, $4.50; 28-gauge American, $4.75; 30-gauge American, $5; bar, $2.50 base.

Pipe—Iron, black, per 100 feet, ¼-inch, $2.40; ⅜-inch, $2.55; ½-inch, $3.35; ¾-inch, $4; 1-inch, $5.75; 1¼-inch, $7 80; 1½-inch, $9.35, 2-inch, $12.50; galvanized—½-inch $4.35; ¾-inch, $5.20; 1-inch, $7.55; 1¼-inch, $10.25; 1½-inch, $12.25; 2-inch, $16.40. Lead, 7.60 per cent., full cnil.

Pitch—Pine, $6.50 per barrel, in less than barrel lots, 4c. per lb.; roofing pitch, $1 per cwt.

Steel Plates, Rolled—3-16-in. $3.35 base; machinery, $3 base; share, $4 50 base; share crucible, $5.50; cast share steel, $7.50; tire caulk, $4.50 base; tire steel, $3 base; cast tool steel, lb., 9 to 12½c.

Tool Steel—8½ to 15c. per pound.

NOTES ON PROVINCIAL LAND SURVEYING

CALCULATION OF COMPASS-SURVEYED AREAS BY DOUBLE MERIDIONAL DISTANCES—PLOTTING BY THE USE OF CO-ORDINATES—RESPECTS IN WHICH THE PRACTICE OF SURVEYING HAS CHANGED

By J. A. MACDONALD, Ottawa, Ont.

IT is generally conceded among surveyors that there is but one absolutely correct method of calculating the area of a compass-surveyed plot of ground. In compass surveying there is necessarily the intrusion of a number of errors, the number generally depending upon the number of courses. This may be readily explained. Five minutes is the closest reading that any surveyor may expect from the compass, and frequently the variation may be ten or even fifteen minutes. In one mile, therefore, where ten minutes mean twenty-three links, the liability of error becomes comparatively great, considering the fact that errors often occur in reading with a good transit, where there is fine precision, to the extent of thirty seconds, and with levels in good order. With such a liability of error, therefore, one may not expect to tie on the starting point of a compass survey. In plotting, it is found necessary to balance the errors of each course, i.e., to divide them *pro rata* among the courses according to length. This is done most satisfactorily by Double Meridional Distances.

Double Meridional Distances.—In plotting a compass-survey which, by the way, must be done by latitudes and departures, there is a favorable feature in the compass which the transit does not possess, that is noticeable. If there is an error in one deflection angle read from the transit, this error arising from improper levelling of the instrument, or its being set up on marshy or infirm ground, all the following courses are intensified in error, a succeeding course depending on the course just taken as a back-sight. With a compass an error in one course does not necessarily lead to an error in the succeeding courses, every course being independent of the other. In plotting a compass survey, therefore, latitudes and departures must, in nearly all cases, be taken, rather than measurements by deflection angles. This, of course, is the proper method of plotting a transit survey also, but it is not always used on account of the extra labor involved in calculating the latitudes and departures. With a table of latitudes and departures, given to minutes, as are now obtainable, however, it is not a laborious task.

The parallel ruler used to be an indispensable requisite of the old compass surveyor. This is found very convenient in plotting—in fact, it is almost the *sine qua non* of a compass surveyor's instruments. Set squares are now used more generally and particularly for railway work. It might be stated that the method of latitudes and departures is now mostly used in plotting railway plans. But in plotting railway plans the meridian, whether magnetic or astronomical, is not passed through each station as is usually done when plotting a field survey made by a compass, and using the parallel ruler, and the protractor for plotting. These two instruments go hand in hand, one being a complement of the other.

There is another method, and the one mostly used in plotting railway plans by latitudes and departures. This is by the use of the set squares and the scale; no protractor being used. On the National Transcontinental Railway, plotting the traverses and the locations with a protractor was forbidden. The latitudes and departures, sine and cosine, being calculated, the latitude was scaled from the last station, using the set of squares to parallel the meridian on the plan and precisely at right angles with it, the distance measured and marked. From this point, and precisely at right angles, the departure was scaled and marked, and the intersection of these lines indicated the new station. This method, while it would answer with a compass survey, is seldom, if ever, used; at least, it was not used by the old surveyors. The protractor and the parallel ruler were usually the instruments used for plotting, and are, as already stated, the most convenient instruments for plotting surveys made with the compass to-day.

Much more attention was given by the old compass surveyors to plotting and lettering than is given by present-day surveyors. It is interesting to note the beautiful work (now considered altogether unnecessary) of some of the old surveyors, which is to be seen in the land office at Ottawa. There must necessarily have been a good deal of time taken over this work, which one would now be ready to call "lost time," but in those days time was not such an important factor as in these strenuous times, and the mighty rush and competition existing at present does not warrant taking any more time over a plan than is absolutely necessary. There is no time now for artistic work, old English letters and elaborate north prints. Stamps and stencils, and even the typewriter, do considerable of the lettering to-day.

Taking the plot, shown on page 498 of *The Canadian Engineer*, (Fig. 2) the plot, Fig. 1, is how it looks when plotted with the protractor and parallel ruler. It will be seen that the last course does not tie to the starting

point, nor will any compass-survey tie unless, perchance, the errors balance. To join the line of the last course with the first will change the bearing of that course, and that would make it different to what it is on the ground, and would vitiate the plan. What must be done, is to balance all the courses, deducting or adding, as the case may be, a little to all of them. This cannot be conveniently or correctly done except by the method of Double Meridional Distances, as explained below.

Table I.

Stations.	Bearing.	Distance.	Latitudes. N.	Latitudes. S.	Departures. E.	Departures. W.
1	S. 63° 15′ E.	11.25		5.06	10.04	
2	N. 80° 00′ E.	11.03	1.91		10.86	
3	S. 50° 10′ E.	12.09		7.74	9.28	
4	N. 16° 00′ E.	6.10	5.86		1.68	
5	N. 42° 30′ E.	13.50	9.94		9.11	
6	N. 70° 20′ E.	11.38	3.85		10.71	
7	N. 3° 15′ E.	9.10	9.08		0.59	
8	N. 34° 30′ W.	10.45	8.61			5.91
9	N. 75° 15′ W.	28.45	7.24			27.51
10	S. 32° 30′ W.	38.15		32.17		20.49
Totals	.....	151.50	46.49	44.97	52.27	53.91
			44.97			52.27
	Error in latitude	1.52	Error in depart.	1.64		

Referring to Table I., it is prepared as follows: By means of a traverse table, or by sines and cosines, find out the latitude and departure for the angle of each course. By adding up the four columns find the difference between the N. and S. columns and also the E. and W. columns. In this instance there we find that the N.'s are 1.52 greater than the S.'s, and that the W.'s are 1.64 greater than the E.'s, causing a serious closing error as plotted by the protractor. (Fig. 1).

To divide the errors prepare a table precisely the same as the foregoing, except that the horizontal spaces are farther apart, and that the adding up of the old N., S., E. and W. columns are omitted. The additional columns are made subsequently. The new table is as Table II.

We have found by the first table that the N.'s and the W.'s are too long, and therefore must be shortened; while the S.'s and E.'s must be lengthened, all of them in the following proportions,—Sum of all the distances: any given distance:: total error of latitude or departure: error of latitude or departure of given distance.

Thus commencing with the latitude of distance 1, we have, as the sum of all the distances, = 151.50: distance (1) = 11.25:: total latitude error, = 1.52: latitude error of distance (1) = .11.

Now, as the latitude of distance, or side, 1 is south, it must be lengthened, so it becomes = 5.06 + 11 = 5.17, as figured out on the new table.

Table II.

Station.	Bearing.	Distance.	—Latitudes— North. (+)	—Latitudes— South. (—)	—Departures— East. (+)	—Departures— West. (—)	Total latitude.	Total departure.	Double meridional distance.
1	S. 63° 15′ E.	11.25		5.06	10.04				
				.11	.12				
				5.17	10.16		— 5.17	+10.16	10.16
2	N. 80° 00′ E.	11.03	1.91		10.86				
			.11		.12				
			1.80		10.98		— 3.37	+21.14	31.30
3	S. 50° 10′ E.	12.09		7.74	9.28				
				.13	.14				
				7.87	9.42		—11.24	+30.56	51.70
4	N. 16° 00′ E.	6.10	5.86		1.68				
			.05		.07				
			5.81		1.75		— 5.43	+32.31	62.87
5	N. 42° 30′ E.	13.50	9.94		9.11				
			.14		.14				
			9.80		9.25		+ 4.37	+41.56	73.87
6	N. 70° 20′ E.	11.38	3.85		10.71				
			.12		.12				
			3.73		10.83		+ 8.10	+52.39	93.95
7	N. 3° 15′ E.	9.10	9.08		0.59				
			.10		.10				
			8.98		0.69		+17.08	+53.08	105.47
8	N. 34° 30′ W.	10.45	8.61			5.91			
			.11			.11			
			8.50			5.80	+25.58	+47.28	100.36
9	N. 75° 15′ W.	28.45	7.24			27.51			
			.29			.30			
			6.93			27.21	+32.51	+20.07	67.35
10	S. 32° 30′ W.			32.17		20.49			
				.34		.42			
				32.51		20.07	0.00	0.00	20.07

Sum of sides	151.50
Sum of northings	45.55
Sum of southings	45.55
Sum of eastings	53.08
Sum of westings	53.08

Again, we have for the departure of distance 1: Sum of all the distances, 151.50: distance 1, 11.25:: total departure error, 1.64: departure error distance 1, .12.

As the departure of distance 1 is last it must also be lengthened, hence it becomes 10.04 + 12 = 10.16, as figured out on the new or second table.

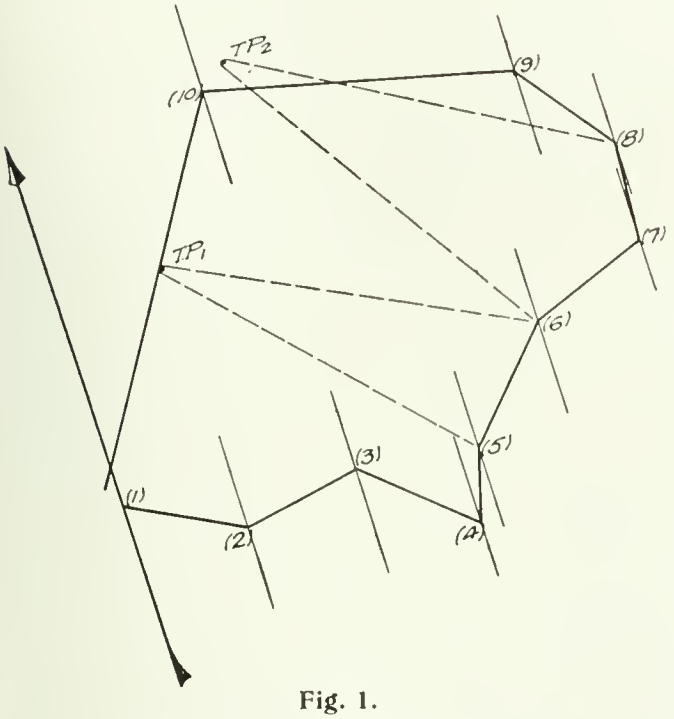

Fig. 1.

Proceeding thus with each side, we obtain all the corrected latitudes and departures shown in the new table. If we now add up the four columns of corrected N. S. E. W. values, we find that the northings equal the southings, and the eastings equal the westings, thus proving that the work is now correct. The corrected latitudes and departures must necessarily change the bearings and distances of every side, but without knowing either of these we can plot the survey by means of the corrected latitudes and departures alone, and without the use of the protector at all. When the closing error is small this is unnecessary, but when the closing error is large, as in this case, in balancing the errors of latitudes and departures, the surveyor usually interprets those errors by inspection, and without taking the trouble of calculating them. By judicious inspection the total errors can be approximately apportioned to each course in both latitude and departure.

Plotting by the Methods of Co-ordinates.—The method of plotting by co-ordinates, i.e., traverses may be performed in two ways: First, the stations shown in Fig. 1 might be laid down from the columns of latitudes and departures, but it would be necessary, in order to plot them, to draw parallel meridians through each station, as shown in Fig. 1, and to lay down each successive station from that which had been plotted before it. As each operation will thus be referred to a new point, in itself dependent on that which preceded it, the sources of error become increased with the number of fresh stations to be plotted. But by referring each station to the meridian of Station 1, both for latitude and departure, as in Fig. 2, any error which may occur in laying down one point is not carried on through the series, the fixing of that point being an isolated operation, independent of every other in the survey. The advantage of such a mode of protection is too apparent to need further comment.

Instead, therefore, of picking off these northings and southings in succession from each other, it is much more proper to prepare the column of total latitudes (column eight) showing how far each of the points, 2, 3, etc., is north or south from Station 1. This being done, the points can be located on Fig. 2, north and south from 1 without moving the scale each time and, of course, with greater accuracy. Such a column is readily formed. Its accuracy is proved by the final result being Zero. A similar column of total departures is prepared (shown in the ninth column of the table) which gives the distances of the points 2, 3, 4, etc., each from the meridian line. Thus, starting from point 1 with side 2, the work likewise proves itself by the final result being Zero.

Starting from the meridian, passing through 1 and the point 1, the first station, mark a point 2′ southward on the meridian, 517 links, and from 2 on a line perpendicular to the meridian, mark a point to the west 1,016 links, which will be station 2, 1—2 representing the amount of southing, and 2′—2 the amount of westing of the point, as referred to the first station 1. Similarly for the others, join stations 1—2, 2—3, etc., which will represent the distance measured, and in the present case the complete lines of the boundary. The details of the survey and the features of the country, offsets, etc., where necessary, are supposed to be put in, as usual, from the field book. The practised surveyor will find the above description sufficient to enable him to plot boundaries or maps, and their lines of road.

In all tables of this kind it is usual to make north and east, plus (+) and south and west minus (—). The use of the symbols save a lot of work. For instance, one column answers instead of two in the table.

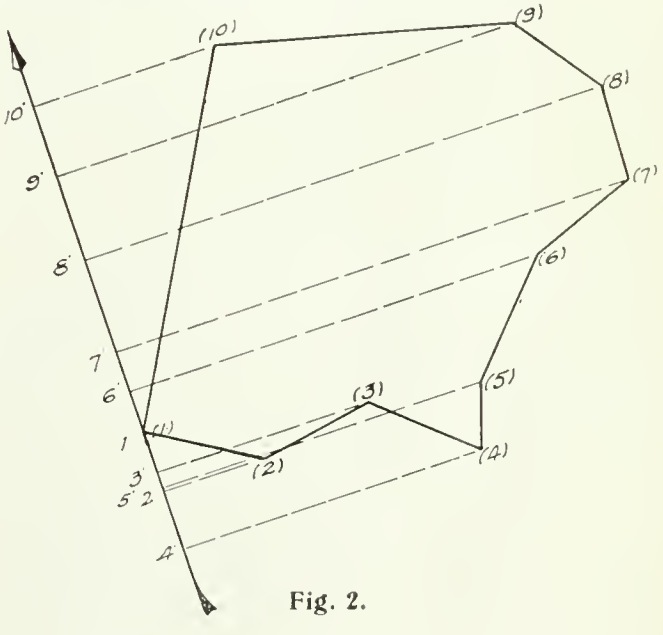

Fig. 2.

Calculating the Area.—The adaptation of the tables to the calculation of areas may be explained as follows: In calculating the area of an enclosure or boundary survey, it is necessary to assume a meridian to which to refer the departures of all stations in the survey. This should in all cases be that of the most westerly station in a boundary survey, as the north differences of latitude become then all positive, and the south all negative multipliers.

Column nine in Table II. contains the departures of each station on the boundary east of the meridian of Station 1, which is stated as the datum, because it is most westerly of the whole survey.

Column ten is introduced solely with a view to facilitating the computation of the areas, by bringing the numbers to be multiplied together into juxtaposition. This column is derived from column eight by simple addition. All operations are performed with such facility that, with the exception of taking out the traverses which occupies a somewhat longer time, the whole table may be filled up in a few minutes.

Table III.

Station	Northings	Southings	Double Meridional Dist.	N. Products	S. Products
1		5.17	10.16		52.527
2	1.80		31.30	56.340	
3		7.87	51.70		406.879
4	5.81		62.87	365.274	
5	9.80		73.87	723.926	
6	3.73		93.95	350.433	
7	8.98		105.47	947.120	
8	8.50		100.36	853.060	
9	6.93		67.35	466.735	
10		32.51	20.07		652.475
				3762.888	1111.881

Subtracting 3762.888 N. from S. products, 1111.881, equals 2651.007, divided by 2 equals 1325.503 square chains, equals 132.55 acres, plus offsets.

It now remains only to calculate the corrected bearings and distances, or length of the sides of the survey, all of which are necessarily changed by the adoption of the corrected latitudes and departures. This operation will only be necessary where the changes are large. To find the bearing from any station, divide its departure (E. or W.) by its latitude (N. or S.); in the table of natural tangents find the quotient, the angle opposite it being the required angle of bearing. Thus, for Course 1, we have $\frac{5.17 \text{ S.}}{10.16 \text{ E.}} = .5088 =$ natural tangent, opposite which is the required angle, 63° 02′. The bearing, therefore, is S. 63° 02′ E.

Again, for the distance or length of any side, from the table of natural cosines take the cosine opposite to the angle of the corrected bearing, divide the corrected latitude (N. or S.) of the side by the cosine, giving the required distance. It will then be necessary to make a table similar to the following:

Table IV.

Stations.	Bearing.	Distance.
1	S. 63° 02′ E.	11.40
2, etc., etc.	.....	.....

This table will contain all the corrections of the foregoing survey, and if the bearings and distances are correctly plotted, they will close perfectly.

Postmaster-General Samuel, of London, Eng., is inviting applications on tender for the construction of the second of three high-power wireless stations to form an Imperial chain from contractors able to satisfy experts by a practical demonstration of the efficiency of their system. The demonstrations will be required to indicate the capacity of the respective systems to carry on continuous and efficient communication, day and night, over a distance of 2,000 miles.

RESTORING THE TRANSCONA ELEVATOR.

THE contracting firm of Barnet-McQueen Company, Limited, of Minneapolis, who designed and constructed, last year, the 1,000,000-bushel grain elevator for the Canadian Pacific Railway at Transcona, Man., which structure sank and listed to an angle of about 30° from the vertical, on October 18 and 19, when almost filled with grain, have announced a plan by which they hope to fully restore it to its proper upright position. The undertaking will be one of the most unique and unusual of any ever attempted in Canada, and will be observed with great interest.

The elevator consists of a working-house and a reinforced concrete bin-house consisting of 65 circular bins of 14 feet 4 inches inside diameter, and 90 feet depth, arranged in five rows of 13 bins each, and 48 interstice bins, also used for grain storage. The binhouse is built on a foundation which is in the form of a floating monolithic reinforced concrete slab, 195 x 77 feet in area, resting upon a soil of stiff clay, about 12 feet below the surface of the ground, and with the clay extending to a depth of 45 feet or more below the surface. Test loads upon the clay indicated a bearing strength of four to five tons per sq. ft. at the time the slab was built, which was in July, 1912.

Readers will remember a previous announcement that on Saturday, October 18th, the huge structure, practically full of grain, began to settle gradually, the ground for a distance of 25 feet or more on the east, north and west sides of the binhouse, heaving up for about 6 feet. During the 24 hours the movement continued until finally an inclination of about 30°, as stated, was reached. The foundation line of the eastern portion then rested about five feet above its proper level, while the opposite side sunk in the neighborhood of 30 feet. While the listing was in progress, the roof structure and the conveyer cupola slid off and were demolished. The removal of this portion of the load apparently checked the movement of the foundation.

It is interesting to note that the structure itself is but little damaged. The bins, containing practically 1,000,000 bushels at the time, remained intact, and it is just announced that practically all of the wheat consigned for lake shipment before the close of navigation, has been removed without loss through waste or fermentation due to the possible intrusion of ground water. This has been accomplished by tapping the bins through the sides, and erecting temporary conveyers between the bins and the railway cars. The removal progressed at the rate of about 40 carloads per day.

Mr. J. G. Sullivan, chief engineer of the Canadian Pacific Railway, at Winnipeg, has expressed himself of the opinion that neither the design nor construction of the building have been at fault in any way, and that the unfortunate occurrence, due to the crushing out of the foundation sub-soil, was ultimately caused by the shifty material below the 30 to 40 feet of clay with which Winnipeg and its vicinity are underlaid. This material makes it almost impossible to go down below the clay even by sinking air caissons. Practically all foundations in the vicinity of Winnipeg are therefore of the floating type, and heavy structures have frequently been known to settle as much as a few inches. In the case of grain elevators, unusual care is always taken to have the grain distributed as evenly as possible to prevent eccentric loading.

Concerning the restoration of the elevator, the contractors are planning to excavate below the eastern portion, allowing it to sink and become perpendicular.

Powerful jacks will then be used to support the structure while the strengthening of the foundation is in progress. When this is completed the elevator will be allowed to rest upon the new surface, and repairs, including the steel roof structure and cupola, will then be made. It is estimated that it will cost approximately $30,000 to restore the structure.

MANITOBA'S LOG-DRAG COMPETITION.

THIS year the first, second and third prizes for gravel roads in the log-drag competition which was inaugurated four years ago under the auspices of the Manitoba Good Roads Association, went to the municipalities of Rockwood, Kildonan, and St. Paul, respectively. In the case of earth roads, they were awarded to Macdonald, Springfield, and Macdonald, in the order named. The winners received their awards at a banquet given by the association on October 29th, in Winnipeg, Mayor Deacon officiating at the presentation. The judges in the competition, who had presented their decision at a previous meeting, were Mr. C. F. Tallman, Street Commissioner of Winnipeg; Mr. A. McGillivray, Manitoba Highway Commissioner, and ex-Mayor Waugh of Winnipeg.

In the course of his remarks, the mayor suggested that it would be well for the municipalities to seriously consider the use of asphalt or concrete as a road material, and expressed his belief that their use would be better throughout the province than the building of any amount of clay roads with gravel surface. He also suggested that it might be more advisable to consider the abandoning of fixed survey lines in construction of new roads, with a view to carrying the roads along better locations, exchanging the road allowances with the land owners.

Hon. Dr. Montague, Minister of Public Works for Manitoba, in speaking of the good roads movement, referred with pride to the streets of Winnipeg, and declared that no city in eastern Canada or in the United States had made the progress in the matter of good streets that Winnipeg has made. He expressed his opinion that the subject of roads in Manitoba was almost entirely an agricultural problem, rather than a motor problem, and was of more importance than nine out of every ten agricultural questions under discussion to-day. It was the problem of bringing the farmer in closer touch with shipping facilities for his products.

Dr. Montague referred to the city of Winnipeg voting $13,000,000 for a new water supply, and $6,000,000 for the installation of a power plant, and intimated that a yearly grant from the Dominion Government of $25,000,000 for the construction of good roads throughout the country would be most timely.

Over 110 members of the association and farmers from surrounding municipalities were present at the banquet, presided over by Reeve Henderson, of Kildonan, president of the association.

At its meeting on October 3rd, the association drew up and sent on a resolution to the Union of Manitoba Municipalities, convening this month at Portage la Prairie,, requesting that the government take over the construction of all the leading highways in the province; that it levy a special tax of one mill on the dollar in the total assessment value of the province, and that the cost of construction be covered by a payment of one-half of the cost of the road from the fund so raised, the government to pay an additional 25 per cent. and the benefited property the remaining 25 per cent.

THE ADOPTION OF FUEL OIL.

THE rapidity with which fuel oil has been displacing coal in many lines of industry has become a point worthy of note the world over. Thirteen years ago oil as a competing fuel with coal was practically unheard of on this continent. The first experiment along the lines on which it has now become so important was the conversion in 1900 by the Southern Pacific Railway of one of their locomotives from the use of coal to oil. That was the beginning. At the present time oil-burning locomotives are operated exclusively upon 20,910 miles of line in the United States, and 587 miles in Canada; and, in conjunction with coal burners, on an additional 4,720 miles in the United States. Some idea of the enormous rapidity of the adoption of oil may be formulated when it is considered that a length of track capable of encircling the globe has been converted from the use of the one fuel to the other in such a short period of time.

The two chief sources at present are the vast fields in Texas and in southern California, as is well known. From the accompanying map it is seen that considerable development has taken place in Texas with lines reaching some distance northward, also in a westerly direction to Southern California. From Southern California the advance has been most pronounced, owing to the facility of water transportation along the coast, and to the expensive variety and unsatisfactory quality of the coal in the Western States.

In a recent article by H. Foster Bain on "Fuel Problems on the Pacific" the following facts were noted: Fuel oil is delivered from Alaska to Peru at prices giving it marked advantage over coal, not taking into consideration the incidental advantages of cleanliness, lower cost of handling, and decreased fire room expenses. Fuel oil is delivered on the Coast at 85 cents to $1 per bbl., equivalent to a cost of $3 to $3 50 per ton for coal, considering fuel value above 3 to 3½ bbls. corresponding in heating value to a ton of coal. The surplus above ground, over 40,000,000 bbls., the extent of territory developed, and the ease with which production is increased, give every assurance of continued supply at a reasonable price for years to come.

The use of oil for locomotive purposes is purely an economic question, depending on the relative cost of oil, coal, and electricity, except perhaps when oil is enforced by law owing to the necessity for fire protection. On the Pacific Coast practically all railway companies, and some who even own their own coal mines, have adopted oil, the use of which is almost as rapidly being taken up at sea, where its use is even more advantageous.

The general points favoring use of oil fuel in locomotives are:—

(1) Saving in time and labor in loading.
(2) Reduction of staff for handling.
(3) Increased cleanliness.
(4) More complete combustion and therefore greater efficiency.

To these may be added, in the case of marine use, a fifth and a sixth advantage—the saving of considerable room in the hold, and the reduction of boiler repairs. The latter would also seem to apply to locomotives, but from the report of A. E. Hudson, inspector for the Canadian Board of Railway Commissioners on the C.P.R. engines in British Columbia using fuel oil, we are lead to believe that such is not the case. According to Mr. Hudson,

since the conversion of these locomotives "a great many leaks have developed in the boilers, such as the crown bolts, and side sheets leaking badly."

It might here be interesting to note, in conjunction with the adoption of oil at sea, the comparative costs of coal and oil on the C.P.R. British Columbia Coast service steamship "Princess Victoria."*

Coal—	Per day.
100 tons @ $4.50	$450.00
9 firemen @ $55 a month	16.50
9 trimmers @ $45	13.50
Food for 18 men	7.56
	$487.56

Oil—	Per day.
344.17 barrels @ 90c.	$314.25
6 firemen	11.10
Food for 6 men	2.53
	$327.87

*From report of G. W. Dickie, published in "The Vancouver Province."

This comparison, together with the above remarks relative to the cost of oil, only applies to the Western States and British Columbia. The conditions in the east are entirely different. The distance from the oil fields and presence of coal in large quantities makes the latter the predominant fuel. The contrast between east and west is clearly shown by the map already referred to. Nowhere is oil used east of the Missouri and Mississippi Rivers, except in the Adirondack Preserve, where its use is enforced by law for fire protection. Relative to the cost of oil in the east, C. S. Sims, second vice-president

and general manager of the Delaware and Hudson Company, states that in 1910 oil for the locomotives of that company, working in the Adirondacks cost $57,260.33 at 2.25c. per gallon, or 28.33c. per engine mile, or $36,045.88 in excess of the cost of doing the work with coal. The cost per engine mile for coal during the same period was 10.46c. For 1912, oil cost $83,703.31, or an increased cost over coal of $56,454.96. For three years, 1910-12, the increased cost of using oil has been $119,077.09. He then states that for a much lower price a wonderfully effective patrol system could be installed. And this seems to be the consensus of opinion in the east, where oil is proposed for fire protection, though it is not disputed that the adoption of oil is much better than the best system of patrol. With the best possible safeguards applied to coal-burning locomotives, it is impossible to prevent sparks being thrown from the stack, whereas with oil there can be no danger except from a little red-hot carbon from the stack; and this can be avoided if the engineer is careful to introduce the "sand seam" at a place where fire would be impossible.

There seems to be no doubt that as a means for preventing the all too frequent forest fires oil fuel far surpasses coal. The question is, should the railways be forced to bear the whole additional cost? Several logging companies operating their own lines have adopted oil, finding that in the long run the advantage is tremendous, owing to reduction of fire loss alone. They are also using oil for donkey engines, and with the increased boiler efficiency have been able to greatly increase their output.

On the other hand, it is noteworthy that, owing to the increased price of oil fuel in the last few years, some companies have been forced to abandon it for coal, chiefly on some of their more easterly lines. Portions of the Rock Island, Sante Fe and 'Frisco roads have recently replaced some three thousand miles with coal burners. Abroad, also, the Australian government lines are abandoning oil because of its enhanced price, whereas at the same time another announcement demonstrating the progressive side of the movement is to the effect that "oil-burning locomotives are being considered for some of the government railways in India."

In conclusion, and extract from the report† of the Commission of Conservation shows the situation in Canada:

"In Canada, the Great Northern Railway is the pioneer among passenger lines. This line is using oil exclusively on its 115 miles of railway in the Cascade Division. This embraces all lines in the vicinity of the Pacific Coast.

"During 1912, the Canadian Pacific Railway established oil burners on its main line between Kamloops and Field, B.C., and on the Arrow and Okanagan branches, making a total of 338 miles. It is now announced that, during 1913, this line will extend the use of oil burners to cover the main line between North Bend and Vancouver, 129 miles, and the Mission subdivision, 10 miles. When this work is finished, the only portion of the main line of the C.P.R. in British Columbia not using oil fuel will be the portion between the eastern boundary of the province (Hector) and Field, 12 miles, and between Kamloops and North Bend, including the Nicola branch, 168 miles; total, 180 miles. The oil-burning portion of the line in British Columbia will then comprise 477 miles."

†Commission of Conservation, Canada, "Forest Protection in Canada," by Clyde Leavitt, M.Sc.F., 1913.

For those requiring more information on this subject than is contained herein, the report of the Commission of Conservation just issued (and upon which the above is largely based) will be of especial value. With this report in mind and several other articles which have been appearing in the scientific press from time to time during the past few years, a world-wide adoption of fuel oil at sea can safely be predicted, and on land in those vast areas over which fuel oil may be more readily obtained than coal. A very interesting point in connection with the fuel problem the world over is that coal is a far too valuable substance for consumption as in vogue at present, and that perhaps before long a new method of coal consumption may be introduced.

BRICK FOR COUNTRY ROADS.

IN Bulletin 23 of the U.S. Department of Agriculture, a treatise is presented on the construction and maintenance of brick pavements, with especial reference to their use on country highways. The authors are Vernon M. Pierce and Chas. H. Moorefield, chief engineer and senior highway engineer respectively of the Office of Public Roads. A brief sketch is given of the development of brick paving, followed by a description of the materials used for paving bricks, and their manufacture. The physical characteristics of these materials, and the methods in vogue for testing them are included. For a concise and authoritative treatment of the subject, readers are referred to this bulletin. We reproduce herewith some information contained in it, respecting the preparation, construction and cost of brick paving in rural districts.

The principal advantages which brick roads possess may be stated briefly as follows: (1) They are durable under heavy traffic conditions; (2) they afford easy traction and good foothold for horses; (3) they are easily maintained and kept clean; and (4) they present a pleasing appearance.

The principal disadvantage is the high first cost. The defects which frequently result from lack of uniformity in the quality of the brick or from poor construction are usually to be traced indirectly to an effort to reduce the first cost or to a popular feeling that local materials should be used, even when inferior.

In the preparation of the subgrade upon which a brick pavement is to be constructed, the essential features to be considered are thorough drainage, firmness, uniformity in grade and cross section and adequate shoulders.

Strong durable curbing should be supplied both on the sides and at the ends. Otherwise, the marginal brick will soon become displaced by the action of traffic and deterioration will spread over the entire pavement.

Satisfactory curbing may be constructed of stone, Portland cement concrete, or vitrified clay shapes made especially for this purpose. With stone the individual blocks should be not less than about 4 feet long and should have a depth of about 18 to 36 inches, depending on traffic conditions and on whether the curb is to project above the surface to form one side of the gutter. A thickness of 4 inches will ordinarily prove satisfactory. Stone curb should always be set on a firm bed of gravel, slag or broken stone, not less than 3 inches thick, and should be provided with a backing of the same material on the shoulder or sidewalk side.

Concrete curbs may be constructed alone or in combination with either a concrete gutter or a concrete

foundation. The advisability of constructing the curb in combination with the foundation, however, is doubtful. Concrete curbs should have approximately the same cross-sectional dimensions as stone curbs and should be constructed in sections not exceeding about 7 or 8 feet in length.

Vitrified clay curbing should be set in much the same manner as that described for stone curbing. The principal additional requirement is that, since vitrified clay is a lighter material than stone and the curb sections are ordinarily shorter, the bedding must be made correspondingly more secure in order to prevent displacement.

The proper type of foundation depends largely on the material composing the subgrade and the character of traffic for which the road is designed. Where the traffic is comparatively light and the subgrade is composed of some firm material which does not readily absorb water, a very satisfactory foundation may be constructed of broken stone or gravel filled with sand. Where the traffic is comparatively heavy, however, or where the material composing the subgrade is defective in any way, a monolithic concrete foundation should be used.

Gravel and broken-stone foundation may be spread in one or more courses, each of which should be from 5 to 9 inches thick before compacting. The stone or gravel should be clean, hard, tough and durable and should be graded in size between certain reasonable, fixed limits. It should be compacted in the usual manner by rolling with a power roller weighing not less than about 10 tons, and sufficient clean, coûrse sand to fill the voids should be spread and flushed into the foundation while the rolling is in progress. When complete the foundation should present a surface uniform in grade and cross section and parallel to the proposed surface of the finished pavement.

Concrete foundations are unquestionably better adapted for brick pavements than any other type. They are practically monolithic in form, nearly impervious to water, and possess a relatively high crushing strength. All of these qualities may be obtained with a relatively "lean" concrete if the subgrade has been properly prepared. Under ordinary circumstances a satisfactory foundation may be constructed of concrete composed of 1 part of Portland cement, 3 parts of sand, and from 5 to 7 parts of broken stone or screened gravel.

It is necessary to provide an adjustable cushion of some kind between the foundation and the brick for correcting any slight irregularities in the surface and to secure an even bearing for the brick. Sand has been found a most satisfactory material and is almost exclusively used. The proper thickness for this sand cushion will of course depend on the extent of the inequalities. Two inches has generally proved very satisfactory.

After the cushion is spread uniformly it should be thoroughly compacted by rolling with a hand roller weighing from 300 to 400 pounds, and any depressions which form should be corrected.

The brick may all be hauled and piled at convenient intervals along the sides of the roadway before grading is begun. Hauling over the finished pavement with wagons until it is complete and opened for traffic should be avoided. If the brick are delivered on the work as needed, they should be unloaded from wagons outside of the curb and carried to the pavers, either by hand or in wheelbarrows. Plank trackways should also be provided over the newly laid pavement for the wheelbarrows when they are used.

The brick should be laid on edge and in uniform courses running at right angles to the line of the pavement, except at intersections; and in order to "break the joints" each alternate course should begin with half a brick. In laying the brick the pavers stand on the pavement already laid and, beginning at the curb each time, carry across as many courses together as they can conveniently reach. The courses should be kept straight and close together, and if necessary each block of eight or ten courses should be driven back by means of a sledge and a piece of straight timber approximately 2 by 4 inches by 5 or 6 feet long. The brick should also be laid close in the courses and should be crowded together, if necessary, after a course is laid, by means of a crowbar inserted at the curb.

After the pavement has been laid and all defective brick have been replaced to the satisfaction of the engineer, the next step is to sweep the surface clean and smooth out all inequalities by means of ramming or rolling. The rolling should be done with a power roller weighing from 3 to 5 tons, and the pavement should ordinarily be rolled in both the longitudinal and transverse directions. The longitudinal rolling should be done first and should begin at the curbs and progress toward the crown. The roller should pass at least twice over every part of the pavement in both directions.

In order to keep the brick in proper position and protect the edges from chipping, it is necessary to fill the joints with some suitable material before the road is opened to traffic. The materials which have in the past been most commonly used for this purpose are sand, various bituminous preparations, and a grout made of equal parts of Portland cement and fine sand mixed with water.

Sand is the least expensive of these materials, but there are several very serious objections to its use as a joint filler. Bituminous fillers vary considerably in quality and efficiency, but all are more or less unsatisfactory. One of the principal objections to their use is based on their tendency to run out of the joints into the gutters during warm weather and to crack and spall out during cold weather. This tendency can, of course, be partially overcome by exercising proper care in selecting the materials. It should also be noted in their favor that brick pavements, the joints of which have been filled with bituminous preparations, are ordinarily less noisy at first than those in which a Portland cement grout filler has been used. The grout filler is unquestionably very much superior from a standpoint of durability, however, and the excessive noise under traffic which has been frequently observed in connection with its use can be largely eliminated by the use of proper bituminous expansion cushions along the curbs. It is, therefore, recommended as better adapted for filling the joints in brick pavements than any other material which has been commonly used for that purpose.

Expansion cushions should be provided for at the time the brick are laid, by placing a board of the required thickness on edge adjacent to each curb. Small iron wedges may be inserted between the curb and the board at the time the board is set. These wedges may be readily loosened and removed after the bricks have been laid and grouted, and may consequently be made to facilitate the removal of the board.

The proper thickness for expansion cushions is a matter concerning which much difference of opinion exists among highway engineers. Some engineers advocate a minimum thickness of 1 inch, while others claim

to have secured their best results by using expansion cushions having a minimum thickness as low as three-eighths inch for very narrow pavements.

The cost of brick pavements varies widely, and is affected by so many influences that it is difficult to attempt to derive a general expression showing the relation between probable cost and local conditions. The prices of brick, as also the prices of the various materials entering into the foundation, vary greatly according to the locality and the freight rate. The cost and efficiency of labor is also far from being constant. Furthermore, the material composing the subgrade and the method of preparing it may exert a marked influence on the cost of the pavement.

If C = cost of cement per barrel, S = cost of sand per cubic yard, A = cost of coarse aggregate per cubic yard, B = cost of paving brick per 1,000, and L = cost of labor per hour, with all materials considered delivered on the work and all costs expressed in cents, then the probable cost of constructing a brick pavement, including the subgrade, a 6-inch concrete foundation, and suitable curbs, may be estimated by substituting in the formula:

Cost per square yard = $1.90\ L + .213\ C + .138\ S + .157\ A + .045\ B$.

The cost as estimated from this formula should, however, be increased by about 10 per cent. to allow for wear on tools and machinery and to guard against unforeseen contingencies. If it is desired to use a different thickness of foundation, it is safe to assume that each inch subtracted or added to the thickness of the foundation will make a corresponding difference of from 8 to 12 cents in the cost per square yard.

PANAMA RAILROAD CROSS-TIES.

SOME interesting data, showing the superior durability of the black guayacum ties used in early days, has been furnished by the chief engineer of the Panama Railroad in his report on the use and life of the hardwood ties laid in the roadbed of the Panama Railroad since 1878. He shows that, according to the annual reports since that date, the greater part of the small hardwood ties used in the original track of the Panama roadbed, as it existed in 1885, were procured from the north coast of Colombia, and were of the variety of wood commonly known as lignum vitae (guayacum recina), now called black guayacum, as distinguished from yellow guayacum, a wood possessing less power of resistance to mechanical wear or decay. Other varieties of wood, such as balsams (or quira), and polvillo, were used in ties, but, practically speaking, the black guayacum is the only variety that has stood the test of time. A few balsam cross-ties, laid in 1900, were taken from the roadbed last year and replaced by larger ties.

All the ties used by the old company on the original track were small, those of black guayacum being "pole" ties, about five to six inches thick, with a 6 to 7-inch face, and 8 feet in length. But, when American Canal operations commenced, these had to be replaced by ties of larger dimensions. However, on a section of the railroad between Empire and Culebra, where the traffic was comparatively light, the small ties were left in the track; and there many of the old small-sized black guayacum ties are still to be found.

When the main line of the roadbed was first double-tracked from White House (near Las Cascades) to Tabernilla, to provide for the movement of spoil trains to and from the Tabernilla dumps, many of the small hardwood ties were removed from this section of roadbed on account of the increased traffic; and, generally speaking, these were found to be in very good condition, showing little, if any, signs of decay—though often badly worn at the rail seat by the mechanical action of the base of the rail, no tie plates being used on the ties, and though frequently "spike killed," caused by the replacing of spikes and changing of rails. However, many of these, and also ties removed after this date, are being re-laid now on the tracks connecting with the new terminal docks at Christobal, a fact which shows that the timber in the ties is practically as good as ever. In the yard tracks, where the smaller size is not objectionable, they are still expected to render a long life of service.

The mechanical wear of the old ties in contradistinction to the decay of the wood is demonstrated by the fact that while the base of the rail, and the driven spikes have cut into the hardwood and weathered it, the material in the balance is as good as ever. The records of the United States have long shown the same experience; but there the ties have probably been used only for 8 or 10 years, whereas local hardwood ties have served for from 20 to 25 years in a tropical climate where all other woods decay in from 3 to 5 years.

Black guayacum is now so valuable for purposes in connection with machinery and manufacturing arts that, for use as cross-ties, it is probably a thing of the past. Both the prices and specifications for guayacum ties show a steady variation throughout the past few years. In the first instance, there has been increase in cost, and in the second, decrease in quality. The regulations state now that the material used shall be black or yellow guayacum, but are more stringent in requirements concerning the hewing and the culling of these, and concerning conformity to a specified table of dimensions. On the other hand, prices have increased 50 per cent. from the year 1898 to the year 1911, though some of this percentage must be discounted to allow for the increase also in the size of the ties. In 1898, first-class ties, 6 x 8 inches by 8 feet, were purchased at $1.50 each; second-class ties, 5½ x 6 inches by 7.9 feet, at $1 each. In 1911, first-class ties 7 x 9 by 8.6 feet, were bought at a cost of $2.25 each, and second-class, 6½ x 8 inches by 8.3 feet, at a cost of $1.75 each.

On good authority it may be stated that substantial progress has been made of late with the scheme which aims at establishing an express service between Great Britain and Australasia, via Canada. The company, which was formed three years ago to carry it out, and in which several well-known British shipowning and shipbuilding firms are interested, is treating with a Canadian syndicate for the purchase of about 400,000 acres of land at Cape St. Charles, on the south-east coast of Labrador, an ice-free port 1,680 miles from Liverpool, or a little more than half the distance between the Mersey and New York. From Cape St. Charles it is proposed to construct a transcontinental railway to the Pacific coast, and if the project materializes, it is claimed that the journey from London to Winnipeg will be performed in five days—giving only two nights at sea—with an additional sixteen days to Sydney, N.S.W., and a corresponding acceleration to many centres in the west of Canada and the United States. The projected highway, with its transpacific extensions to Hongkong and other British possessions in Far Eastern waters, is planned to serve the purposes of war as well as the pursuits of peace.

SKIP-HOISTS.

By Reginald Trautschold, M.E.,
Consulting Engineer, New York City.

THE conveying and elevating machinery so far discussed has all been of the continuous type—that is, apparatus particularly adapted for the purpose of handling material in a continuous stream and thereby realizing large capacity with minimum expenditure of power and time—but there is an equally large class of conveying machinery that performs its operations of handling materials only intermittently or in a succession of cycles; i.e., a cycle of productive work and then one in which the apparatus rearranges itself for the next cycle of productive operation. Particularly is this arrangement carried out in the case of elevating machinery in which single buckets are loaded, raised and then unloaded in some other plane, or where the loaded bucket is raised and carried over a more or less horizontal plane to the discharging point and there emptied, after which operations it is returned to the loading point for more material. This intermittent type of apparatus includes steam shovels, locomotive cranes, traveling bridges of various descriptions, cable-ways, hoisting towers and numerous combinations and modifications of such apparatus; all of which may have a varying loading point, various points or locations at which discharge of load may take place and a more or less varying path over which the loaded bucket may travel between loading and discharging. Such apparatus may be used either independently or in combination with any of the various types of conveying and elevating apparatus described in this series of articles. When used in combination with such equipment, storage hoppers or similar devices are necessary, from which the intermittently operated apparatus may take or discharge its load—occasionally hoppers are used for both operations. Such hoppers simply serve to convert an intermittent to a continuous supply, or vice versâ, and as a temporary storage from which the conveying system can conveniently obtain its load or to which the loaded apparatus can economically and efficiently discharge. The continuous type of conveying and elevating machinery discharges to such temporary storage hopper in a continuous stream and other continuous or intermittent handling equipment can take its capacity therefrom so long as the supply to the hopper is adequate. Hoppers supplied from intermittent apparatus can similarly be used to supply load for other intermittent equipment or to load continuous conveying and elevating machinery, as the discharge from the hopper may be proportioned so that the latter type of apparatus can take only its capacity and will automatically take such amount so long as the supply to the hopper is sufficient.

Another class of conveying and elevating machinery of the intermittent type travels along fixed paths, although in some types of such equipment the loading and discharging points are not necessarily fixed. Common examples of such apparatus are car-hauls, skip-hoists, etc., etc. In many installations such equipment is of even greater economic value than continuous handling apparatus; and, although it is impossible to present formulæ for ascertaining even the probable economic value of such equipment, expressed in terms of net operating cost (each and every installation presenting a distinct and individual problem that must be solved independently) or even to derive equations for approximating the cost of equipment, the importance of this class of machinery is such that a short description of certain types is necessary in forming a comprehensive opinion of the respective value of various mechanical material handling equipments.

When materials are being handled that by their weight, chemical properties, etc., may be excessively destructive to a succession of necessarily comparatively inexpensive buckets, or when the supply of material is of necessity quite intermittent, one of the most satisfactory equipments is the skip-hoist, which primarily consists simply of a skip, or bucket, that is loaded, carried to the discharging point, dumped and then returned to the starting point for another load. As ordinarily employed, skip-hoists are installed for elevating operations only, the skips running either on vertical or slightly inclined tracks, although special forms of skips can be constructed that will permit travel in a more or less horizontal path. The skips themselves may be of almost any conceivable shape or size, depending largely upon the nature of the material to be handled and the capacity desired, and may be run at almost any speed up to 600 feet per minute, and occasionally at even greater speed. They are customarily equipped with bails by which they are hoisted and which are attached to the skips below and to one side of their centre of gravity so that they automatically tip and unload on reaching the discharge point, the tracks here being so located as to allow such position of skip. The skips usually run on four wheels and various systems are employed for compelling the skip to follow the proper tracks when discharging. One very satisfactory arrangement, that employed in the installation illustrated, is to run double tracks the full length of the skip travel, the inner tracks being curved off over the receiving hopper or discharge chute as the skip approaches the end of its upward travel. In such construction, the bail is attached to the skip so that the lower pair of wheels press against and run on the outer set of tracks, while the upper set of wheels, those nearer the open end of the skip, press against and run on the inner set of tracks—those curving out toward the discharge point. With this arrangement, the wheels do not leave their respective tracks, so that when the discharge takes place the skip is upset while the flanges of the wheels, nevertheless, maintain the skip in its proper vertical plane. In installations where the track of the skip is appreciably inclined to the vertical the outer set of track is dispensed with, except for a section at the top of the hoist where the tension on the skip bail would tend to pull the skip from its tracks but for the restraining action of this outer guide. Various other arrangements of tracks are occasionally resorted to, but the object in all cases is to so guide the skip that a continuance of pull on the hoisting cable tends to upset the skip and discharge its load.

Customarily, skip-hoists are either of the balanced type or, if but one skip is used, a counterweight is employed to compensate for the weight of the skip itself. A balanced skip-hoist is simply an arrangement of two skips that rise and fall alternately so that the constant dead weight of one skip balances the other and the power required for operation is simply that necessary to raise the load and the varying unbalanced weight of the cables as the skips or skip and counterweight rise and fall. The maximum weight of the unbalanced cables is comparatively small, as steel cables—necessarily of relatively small diameter and correspondingly little weight—are nearly invariably employed, so that for all practical purposes the power requirements of a skip-hoist is simply the amount necessary to raise its maximum load in the given time, to which must be added a sufficient amount

to care for the friction losses, etc. These losses are usually figured as fifty per cent. of the power theoretically necessary for handling the load. Formulæ XXV. and XXV.-a are equations ordinarily employed in figuring the power requirements for skip-hoists and, though apt to give somewhat larger results than necessary, if the installation be carefully designed and erected, are conservatively correct and advisably employed.

Horsepower:

$$HP = \frac{15\ WH}{10000} \qquad \text{Formula XXV.}$$

$$HP = \frac{45\ Qw'VH}{1000000\ (2H + V)} \qquad \text{Formula XXV.-a}$$

Where:—

W = Weight of load handled in tons per hour.
H = Height of hoist (distance that skip travels) in feet.
Q = Capacity of skip in cubic feet.
V = Velocity (speed) of skip in feet per minute.
w' = Weight of material handled in pounds per cubic foot.

Though the great variety of skips that are employed and the numerous conditions that must be met in even a simple installation of skip-hoists make it impossible to derive a formula for ascertaining the cost of equipment, such cost is, nevertheless, very easily arrived at, knowing the conditions of the installation, for the cost of any type of skip is easily estimated, the cost of cables per foot even more easily arrived at, when the weight of the fully loaded skip and also the speed at which it is to be operated are known. Similarly the cost of the necessary hoist, counterweight, sheaves, etc., can be arrived at and, knowing the probable initial cost of the equipment, it requires but simple calculation to obtain the probable net operating cost of the system. Depreciation, renewals and repairs seldom exceed 15 per cent. per year of the initial cost.

The true economic value of the skip-hoist is not based so much on the net cost of its operation, however, but rather upon its convenience and its ability to solve many difficult elevating problems. For instance, in the handling of pig iron and similar heavy materials the skip-hoist often proves an exceedingly efficient and economical system to install, particularly as were such material elevated by an ordinary bucket elevator the wear and tear on the elevator buckets would be very excessive, to say nothing of probable breakage which might be so great as seriously to cripple the system. In the handling of brittle and easily broken materials, such as coke, the skip-hoist also finds extensive use, for if care is taken in the loading of the skips and they are not too roughly and suddenly unloaded, much breakage that cannot be properly guarded against in a bucket elevator is avoided. Special skips can be constructed of materials that will resist high temperatures, the action of acid or alkali fumes, and other destructive characteristics of certain materials—whether they be liquid or solid—so that the skip-hoist not only ranks in economic value with any other type of conveying or elevating machinery, but very frequently is the desirable equipment to install.

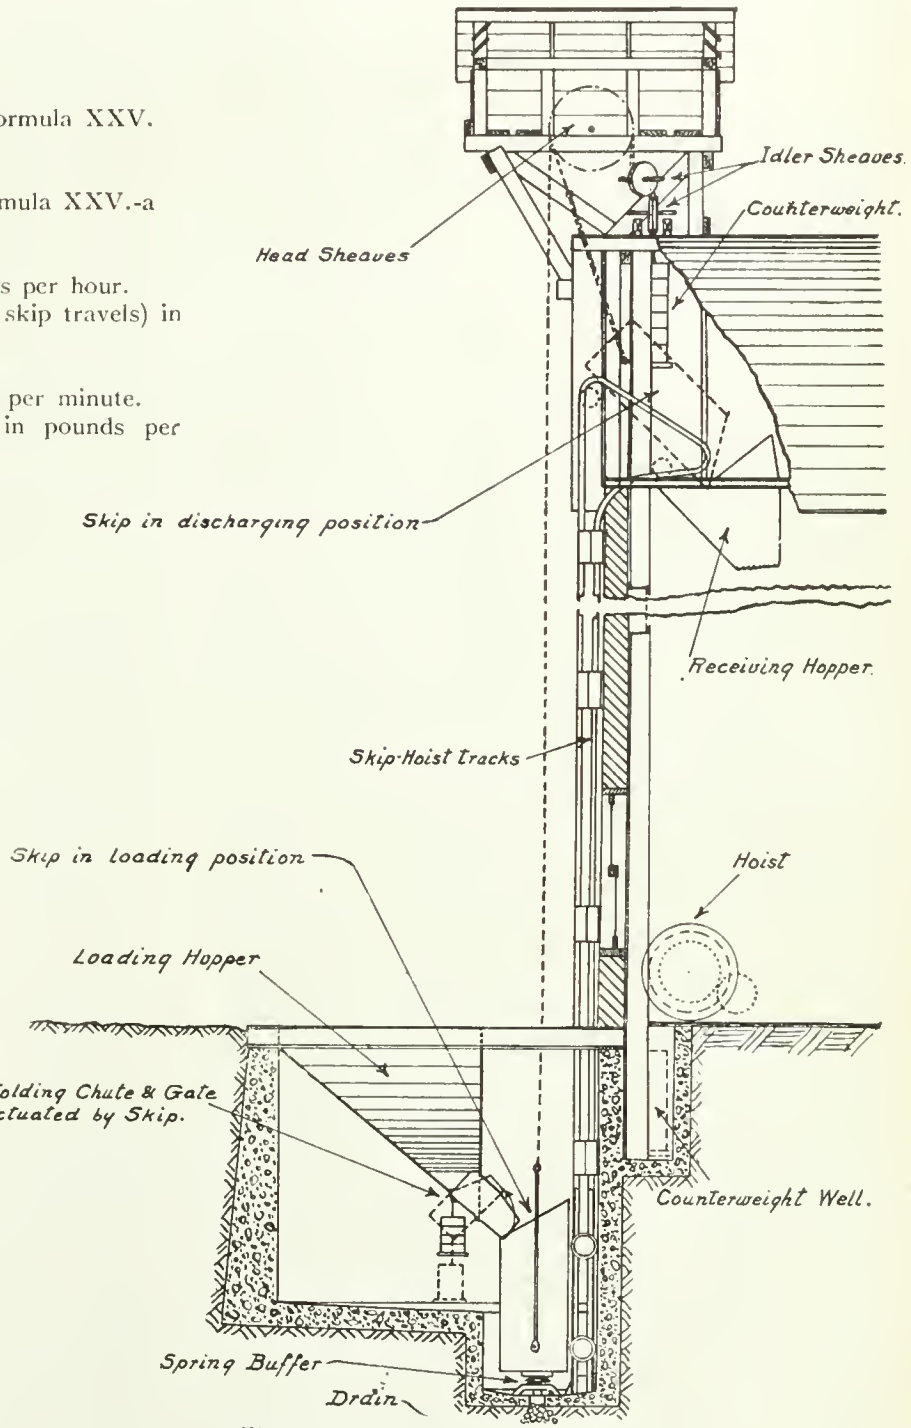

Fig. 1.—Typical Skip-Hoist Lay-out.

Canada owns thirty-eight per cent. of the world's supply of pulp wood, although it is only producing four per cent. of the world's paper. The United States has eighteen per cent. of the world's supply of pulp wood and makes forty-two per cent. of the paper.

FIXED CARBON TEST EMPIRICAL

THE SECOND OF A SERIES OF ARTICLES BY PROMINENT CHEMISTS REGARDING THE VALUE OF LIMITING THE PERCENTAGE OF FIXED CARBON IN ASPHALT

By LEROY M. LAW,

Chemist, The United States Asphalt Refining Company

UNDER ideal conditions, purchasing under specifications is beneficial to both consumer and producer. The former is enabled to state in precise terms his exact requirements in the way of material needs. This establishes quality and, as a result, all competitors are placed upon an equal footing, and competition resolves itself into the real objective: competition in price alone.

To the producer it means, first of all, that he is given an equal chance with others in the trade, and as all deliveries are to be rapidly inspected, he feels safe that another dealer cannot submit a profitless price in the hope of furnishing an inferior article. The mutual understanding, or to use the definition of contract, the "meeting of minds," is brought about through the agency of the specification proper and it is therefore highly important that this feature should receive serious consideration.

Its prime object is to define the requirements in terms which permit of ready interpretation, avoiding all possible uncertainties which may give rise to disputes under the contract. This point is vital and really forms the foundation of this great system, yet even in some of our most elaborate specifications its importance is frequently neglected.

In many of the early types we have seen such requirements as "The material must be . . . brand or equal thereto" and "the material shall have given satisfactory service under similar conditions for such a period of time." With such crude clauses, specifications fail of their purpose, for the actual requirements are at best but vaguely stated, and the producer has no way of ascertaining if his wares are "equal to" or have "given satisfactory service" in the judgment of him who reviews the bids and makes the award.

Such conditions, especially unfair to the manufacturer, are, it is true, rapidly disappearing, yet to-day, in many of the so-called scientific specifications, the adoption of requirements based on arbitrary methods of analysis has placed the honest producer in an equally uncertain and embarrassing position. One of the requirements of this nature, which has gained, and still holds, surprising popularity in many current bituminous specifications, is that limiting the so-called "Fixed Carbon." It is, indeed, difficult to understand just how this requirement even secured a foothold in asphalt specifications.

"Fixed Carbon" is a test stolen from fuel chemistry, where it serves to indicate the coke remaining after the gaseous constituents have been removed by heating the material, with exclusion of air, under prescribed conditions. Those who have had any experience whatever in fuel work know full well that this test is purely empirical and that the variations among different operators, especially in different laboratories, is often considerable.

A committee of the American Chemical Society gave considerable study to the matter some years ago and in 1899 recommended the procedure (see J. A. C. S. Vol. XXI., No. 12) that is now followed in conducting this determination. It is understood, however, that this method is not applicable even to some fuels like lignites, which are very prone to spark. How much more inapplicable, then, will the method be to softer materials, like the asphalts and road oils, which have also the disagreeable tendency of foaming out of the crucible at certain stages of the heating.

Chemists should know that city illuminating gas, their source of heat, varies in different localities. In fact, in some cities the composition is entirely different from that of others, hence a variation in heat, to say nothing of the difference in type and condition of the burners employed. It has been found that the degree to which the platinum crucible is polished has also an effect on fixed carbon results, and there are doubtless other sources of variation not as yet discovered.

The point is that engineers and chemists who advocate such requirements in their specifications, fail to realize these features, and their resulting effect on accuracy. Fieldner, of the U.S. Bureau of Mines, in speaking of the Fixed Carbon test, (see J. I. E. C., Vol. 5, No. 4) makes the following statement in regard to coal, and what he says in regard to coal is equally applicable to the fixed carbon in asphalts, for the same procedure is used with both materials:—

"The volatile matter and fixed carbon represent the relative proportions of gaseous and solid combustible matter that may be obtained from the coal by heating it in a closed vessel. This is done by heating a finely powdered sample in a small covered platinum crucible, in the flame of a Bunsen or Meker burner, for exactly seven minutes. The volatile matter consists mainly of the combustible gases—hydrogen, carbon monoxide, methane, and other hydrocarbons and some non-combustible gases, such as carbon dioxide and water vapor. The volatile matter does not include water present in the coal as moisture at 105° C. (221° F.).

"The residue of coke left in the crucible after deducing the ash is reported as 'fixed carbon.' The 'fixed carbon' does not represent the total carbon in the coal, as a portion of this element is driven out in combination with hydrogen in the volatile matter; furthermore, 'fixed carbon' is not pure carbon, but still contains several tenths per cent. each of carbon, hydrogen and oxygen; from 0.4 to 1.0 per cent. nitrogen; and about half the sulphur that was in the coal.

"It should be clearly understood that the terms 'volatile matter' or 'volatile combustible matter' and 'fixed carbon' do not represent any definite compound which existed in the coal before heating. The method of determination is purely arbitrary and variations of temperature and rate of heating will cause variations amounting to several per cent.; even with a strict adherence to the method recommended by the American Chemical Society, variations of three and four per cent. in both the volatile

matter and fixed carbon may occur in different laboratories. One of the most prominent factors in causing variations is the temperature at which the crucible is heated.

"It is especially pronounced in anthracite and semi-bituminous coal. It is not improbable for one laboratory to report 4 per cent. and another 7 per cent. volatile matter on the same sample of anthracite, or 14 per cent. and 17 per cent. respectively on the same sample of Pocahontas coal.

"The different percentages of volatile matter were actually produced by different conditions of heat treatment. Caution must, therefore, be observed in making comparisons of the volatile matter and 'fixed carbon' in proximate analysis made in different laboratories. Even determinations made at the same laboratory by the same analyst may vary to the extent of 0.5 per cent."

If such wide variations do occur with coals, what, then, should we expect when the method is applied to soft asphalts and even oils? As a chemist of one of the large asphalt companies, I have observed this fixed carbon requirement enforced to extremes and yet to no purpose or benefit to the consumer. The yield of fixed carbon cannot be controlled in the process of manufacture, unless through gross carelessness in coking material. In this case, the defects will be shown far more accurately by increased insoluble matter in the various reagents employed in bitumen analysis.

Some weeks ago the writer prepared two samples of bituminous material of different consistencies, dividing each sample into several portions. These were sent to several laboratories to make the fixed carbon tests. The operators selected were not the usual commercial laboratories, but chemists who are especially qualified and equipped for asphalt work, and regarded as our foremost experts in the branch of the profession.

The tabulated results of their work follow:--

Results on Fixed Carbon.

	Sample No. 213.	Sample No. 215.
Laboratory A	12.(illegible)	(illegible).
" B	13.62%	16.85%
" C	10.91%	13.13%
" D	12.52%	17.54%
" E	12.63%	17.20%
" F	17.10%	22.00%

Inspection of the figures shows a variation in fixed carbon on these same samples of over 6 per cent. in one case and nearly 9 per cent. in the other! When experienced operators such as the above differ by these amounts on identical samples, is there any wonder that with chemists generally the variations are even greater?

It is to be regretted that chemists do not study these tests before incorporating them in their specifications and extend to good materials and their honest manufacturers a just consideration. If fixed carbon in Baltimore is different from fixed carbon in Pittsburgh and, if in any one place the results are to vary from day to day, what possible value can the test have as indicating the value of a material? Furthermore, how is the manufacturer to test his products in every consumer's laboratory, to ascertain conditions prevailing in each of them?

Some days back it was our misfortune to have a shipment of asphalt rejected because the fixed carbon, as determined in the customer's laboratory, ran from one-tenth to three-tenths in excess of the prescribed limit. I had previously tested the batch from which this shipment was made, and found the fixed carbon considerably below the requirements of the specifications. Think of a scientist holding up a material on such a narrow margin as this, when even the most precise chemical methods are seldom within this limit of accuracy, especially as carried out in ordinary commercial testing. An absurd feature of the case is that another carload from the same batch was accepted as meeting the requirements, the inspecting chemist doubtless being unconscious of the variation he was experiencing in his own laboratory.

Suffice it to say that such a clause as Fixed Carbon, in its present empirical state, and coupled with a narrow and rigid interperation, is not only a discredit to the profession, but destroys the value of a sincere specification.

It has been stated that the principal object of the specification is to lay before the manufacturer in a clear, concise manner the requirements that are to be met. When he is unable to interpret these with a reasonable and standard equipment, the purpose of the specification fails.

The rapid development in bituminous highway work during recent years has been accompanied with an accumulation of inspection methods, desirable and questionable ones springing up together, and the many young chemists in this field of work doubtless look upon them as methods of established scientific value. Other chemists, with only time for routine work of testing, become advocates of such requirements as they might otherwise suppress. Furthermore, specifications of one city or municipality are frequently copied from those of another which, presumably, from a longer experience in bituminous work, is looked upon as a criterion in such matters.

And so, by these and other unstudied procedures, some asphalt specifications have been brought to this present empirical condition, and the time is at hand for chemists in this branch of the science to co-operate in weeding out the tangled field of laboratory methods. No one chemist should, and no true scientist will, decide that check results in his own laboratory establish the reliability of a test or method of analysis. Such is at least to be expected.

A true scientist will endeavor to ascertain what the procedure shows in the hands of others, presuming, of course, average qualifications in experience and skill.

If, as a result of such study, "Fixed Carbon" is found to be of value, then it will be of interest to all concerned to adopt definite procedures and agree on the imitations of accuracy. If it cannot be developed into real scientific test, capable of yielding concordant results in the hands of all qualified chemists, then it should by mutual consent be abandoned.

In its present empirical condition, it cannot be of any possible assistance in determining the quality or even the uniformity of a product but, on the other hand, its employment frequently works injustice to valuable materials.

Until the status of the "Fixed Carbon" test is better established, would it be any more than fair to manufacturers to omit such a requirement from bituminous material specifications?

Postmaster-General Samuel, of London, Eng., has appointed a committee of scientists to investigate the subject of wireless telegraphs and report on possible improvements for the service on land and sea. The Right Honorable Charles Edward Henry Hobhouse, chancellor of the Duchy of Lancaster, is chairman of the committee.

THE SELECTION OF MATERIALS FOR MACADAM ROADS.*

By Logan Waller Page,
Director U.S. Office of Public Roads.

OF all the factors which go to make up the perfect macadam road, there is undoubtedly none more potent than that of the suitability of the material which enters its construction. A road may be located, drained and constructed along the very best lines and according to the most approved methods and be a total failure if the material of which it is built has been poorly chosen. It is perhaps not too much to say that large sums of money are wasted annually in this country because too little importance is attached to this phase of the road problem. The engineer is then, at the very outset, confronted with the important problem of selecting the most suitable material for his work, and on the care with which he performs this task depends in a large degree the success or failure of the road he is to build. The purpose of the present paper is to discuss in some detail the methods which may be used in approaching this problem, with special reference to the value of laboratory tests as an aid in the selection of suitable materials for roads.

There are two ways in which the engineer may avail himself of the information necessary to a proper selection of a road material. The first and only certain one is to make an actual service test on the material under observation, and under the same conditions of traffic and climate to which the proposed road will be subjected. This method is, of course, impractical except in certain rare instances, due to the length of time which must elapse before definite results can be obtained. The second method is, by means of short-time laboratory tests to approximate as nearly as possible the destructive agencies to which the material will be subjected on the road, supplementing the knowledge thus gained by a study of the results already obtained in practice on material of a similar nature.

The laboratory testing of road building materials originated in France over forty years ago, and was introduced into this country by the writer in 1893, when he became Director of the Road Material Laboratory of the Lawrence Scientific School at Harvard University. The United States Government became interested in this work shortly afterwards, establishing, in 1900, a laboratory in the Department of Agriculture, at Washington. This laboratory is now a part of the Office of Public Roads, and has thus been able to give much assistance throughout the country in regard to the proper selection of material for macadam roads.

The three most important properties which a rock should possess in order that it may successfully resist the destructive agencies to which it is subjected are hardness, toughness, and cementing value.

Hardness, from the road builder's point of view, may be defined as the resistance which a rock offers to the displacement of its surface particles by friction. It is well illustrated in practice by the grinding action of iron-tired vehicles which tend to reduce to dust the rock fragments of which the road is composed. This property is determined in the laboratory by a special method, the essential features of which are as follows:—

A core 25 mm. in diameter is drilled from a sample of solid rock by means of a core drill. After being accurately weighed, it is held in a perpendicular position against a cast steel disc revolving at the rate of thirty-three revolutions per minute, while crushed quartz sand of a standard size is fed upon the disc to act as the abrasive agent. After one thousand revolutions of the disc, the core is again weighed, the loss calculated, and a measure of the hardness of the rock thus obtained.

Toughness, or resistance to impact, is a measure of ability of a road material to resist the pounding action of traffic such as is caused by the shoes of horses, etc. It is determined in the laboratory in the following way:—

A cylindrical test specimen of the rock 25 mm. by 25 mm. is taken from the core used in the hardness test, and subjected to the impact of a two-kilogram hammer through a spherical end plunger in a machine especially designed for the purpose. The test consists of a one-centimeter drop of the hammer for the first blow, followed by an increase in the drop of one centimeter until failure of the test piece occurs. The height of blow at failure is taken to represent the toughness of the specimen.

The combined effect of the mechanical agencies causing wear is very effectively determined by means of the Deval abrasion test, which has been the standard for over thirty years, and which is conducted essentially as follows:—

Five kilograms of the rock to be tested is broken so as to number as nearly as possible fifty pieces, and is placed in an iron cylinder, mounted in such a way that the axis of the cylinder is inclined at an angle of thirty degrees with the axis of rotation of the machine. After ten thousand revolutions of the machine at the rate of thirty-three per minute, the material is taken out and sieved through a 0.16 centimeter sieve, the material passing being that used in calculating the percentage of wear.

The cementing value of a road stone is that property which causes the fine rock dust to act as a cement and thus bind the coarser fragments of which the road surface is composed into an impervious shell. A laboratory test to determine this property was devised several years ago by the writer, and is conducted substantially as follows:—

Five hundred grams of the material to be tested is broken to about pea size, and placed, together with a sufficient quantity of water, in an iron ball mill. Five thousand revolutions of the mill reduces the mixture to the consistency of a stiff dough, which is moulded by means of a hydraulic moulding machine into cylindrical briquettes 25 mm. by 25 mm. in size. After drying twenty-four hours, these briquettes are tested by impact in a machine especially designed for the purpose. A one-kilogram hammer falling upon an intervening plunger, which in turn rests upon the test piece, is allowed to drop from a height of one centimeter until failure of the specimen occurs. The number of blows causing failure is used to represent the cementing value of the material.

It will readily be seen from the foregoing that a very accurate preliminary idea of the properties of a road stone may be obtained by means of laboratory tests. Many years' experience in testing these materials have made it possible to adopt certain standards of excellence which, when used intelligently and in conjunction with the other factors in the case, are of much value in selecting suitable materials for water-bound roads.

The results of laboratory tests alone, however, are not sufficient to judge of the suitability of a rock for road

*Read at American Road Congress, Detroit, Mich., Sept. 29 to Oct. 4, 1913.

building purposes, unless supplemented by additional information as to, (1) the character and volume of the traffic to which it is to be subjected; (2) climatic conditions under which it is to be used, and, (3) its name and general character, including, if possible, its mineral composition. In addition to the above, consideration in any specific instance should be given to such matters as the availability of the material, especially with reference to cost, transportation facilities, etc.

The value of taking these factors into consideration will be briefly illustrated below.

It is a well-known fact that a given road rock is far from being equally well suited to different traffic conditions. A high-grade trap rock would be as unsuitable as it would be uneconomical on a road subjected to light traffic, in that the dust worn off would not be sufficient to bind the coarser fragments together, and the road would consequently ravel. On the other hand, the comparatively soft limestone would be well adapted for the light traffic road would quickly pound to dust if subjected to conditions which would hardly affect the trap.

As a general rule, it may be said that the ideal rock for any particular road should be just so hard and tough that the fine material worn off by the action of traffic would be sufficient to supply that lost by the physical agencies of wind and rain. By correlating the information obtained by observing the behavior of the various rock types under different traffic conditions, with the results of laboratory tests on material similar in character, it has been found possible to determine quite definitely under just what conditions any given material would be most suitable, even before it had ever been used in road construction.

Many years of observation of the behavior of the various road building rocks in service has demonstrated the fact that, as a general rule, certain classes of material possess for particular purposes distinctive advantages over others. It is obviously of advantage, therefore, to know the general type of the material under observation, in order that an intelligent comparison may be made between it and the material of a similar nature which has already been used. The different varieties of trap, for instance, such as diabase, basalt, etc., are generally considered to make the most satisfactory road material, especially when the traffic is heavy enough to supply by wear the dust lost from natural causes. The limestones, as a class, being softer and less tough, are, as a rule, better adapted for light traffic than the traps. Laboratory tests in these cases are, therefore, mostly of value in enabling the engineer to make a definite choice between a number of materials which in a general way might be considered as suitable for his work.

The granites, owing to lack of toughness and cementing value, are, as a rule, only suitable for the foundation courses in plain macadam construction. Here the value of taking into consideration the character of the rock tested may be illustrated by the fact that frequently granites are found by laboratory tests to have good cementing values, due to highly altered minerals, when, as a matter of fact, such material should not be used on account of the ease with which it disintegrates under traffic.

Foliated material, such as gneiss, schist, slate, etc., should never, of course, be used when better material is available. Material such as quartzite and marble should also be avoided, the first on account of its hardness and lack of cementing value, and the second because of its crystalline structure and general lack of durability.

The availability of various materials considered for use in road construction should, of course, be considered, and is highly important, especially from a financial standpoint. In considering this point, however, care should be taken not to lose sight of the other factors in the case. Experience has shown in innumerable instances where poor material has been used because it was cheap that money would have been saved in the long run by the use of a superior rock, even though shipped from a distance and costing considerably more at the outset. There are cases, however, where local material may be used advantageously. It is in such instances as these that engineering judgment, combined with laboratory results, is necessary for proper selection.

An accumulation of data resulting from the great number of tests made on road building rocks in the government laboratory has quite recently made possible some very interesting investigations concerning the relation between the properties of hardness and toughness. By plotting numerous values of these tests, it was found that, in a general way, hardness increases with toughness and that, whereas for low values of toughness the hardness was extremely variable, as the rock became tougher the hardness showed less and less deviation from an average of the plotted points. The significance of this fact is that the property of hardness appears to be invariably associated with that of toughness, although the reverse is not the case. It seems, therefore, that for a quick determination of the qualities of a road-building rock, the hardness test might possibly be omitted, since material which satisfactorily passes the toughness requirement invariably appears to be hard enough for use in road construction.

When rock is to be used in bituminous construction, the importance of some of the above-mentioned tests is diminished. The cementing value, for instance, may be practically disregarded when the use of an artificial binder removes the necessity for dependence upon a dust bond. A tough rock is, of course, preferable, and more especially when the surface is to withstand the shock of heavy traffic, but both toughness and per cent. of wear become less important in the body of the road with bituminous construction when the surface is maintained by occasional surface treatments to preserve a wearing mat with a hard and tough aggregate.

Since public health and comfort have universally demanded an abatement of the dust nuisance, and economic maintenance is correlated with their demands, a few words on the selection of dust preventives and road binders cannot be out of place in a discussion of materials for macadam roads. The selection of a form of treatment or construction must be governed by a full consideration of the volume and character of traffic which the road surface is called upon to carry. In rural sections where a macadam road is subjected principally to the average farm traffic and a relatively small number of automobiles, a surface which is in good condition at the outset may be economically and satisfactorily maintained by an occasional application of one of the lighter dust laying tars or oils. The purpose in a case of this character is simply to presrve an already good surface by keeping the products of wear saturated with a material that will prevent them from being removed from the road surface. This purpose is readily best accomplished by a product that is not possessed of marked binding qualities —a material that will not pick up nor "ball" when mixed with dust only. Hygroscopic salts and other non-bituminous dust preventives have also served the above

purpose successfully where climatic conditions favor their particular characteristics.

The value of a simple dust preventive decreases, however, with an increase in the volume of automobile traffic, and a more permanent form of wearing surface then becomes necessary. Up to a certain limit, and particularly on park roads, this character of traffic is successfully provided for by means of an annual surface treatment of oil or tar covered with cleaned screenings or fine gravel. For cold surface treatment, the oils which give particular satisfaction are the natural or partially refined products which, through laboratory tests, are shown to consist of low-boiling constituents carrying in solution a relatively high amount of heavy adhesive asphaltic base. For most successful surface treatment, it is essential that an oil shall develop decided adhesive qualities in the residue from the standard volatilization test at 63° C. Tar products should be free from water, and it is believed that their value for surface treatment increases with the decrease in the free carbon content.

When the traffic becomes of such a character and magnitude as to cause a too rapid deterioration of a surface mat, the macadam must be constructed or resurfaced with a heavy binder as an integral part of the upper two or three inches of the wearing surface. The selection of a binder, whether it be a tar or asphalt product, now becomes dependent on several factors, among which the method of construction, character of the aggregate, and climatic conditions are most important. For instance, a dense aggregate may permit of the use of a lighter tar than will a poorly graded one; or a lighter tar or softer asphalt product would be specified for northern latitudes rather than for use in the south. A single standard for all materials and conditions can not, therefore, be established, but with the various factors in mind a specification can be drawn to cover the consistency and desirable chemical characteristics. In fact, in the purchase of road materials for whatever purpose it should be to the advantage of the producer as well as a protection to the consumer, that a definite specification be required. All shipments when received should be submitted to laboratory tests that will insure fulfilment of these specifications.

LONDON'S WATER STORAGE AND SUPPLY

In the annual report of the Metropolitan Water Board, of London, England, it is shown that the board has under its control subsidence and storage reservoirs of a capacity of some 15,000,000,000 gallons. The normal consumption of the 6,688,555 people within the board's area is more than 200,000,000 gallons per day. For the year ending March 31st, 1913, the total amount of water supply was 86,248.9 million gallons, or 387.9 million tons. The average daily consumption per head was 35.49 gallons, compared with 36.49 gallons in 1911-1912. The usual daily allowance could be supplied from the reservoirs if they were all filled to their utmost capacity, for eleven weeks; and as a rule the board keeps in store a supply sufficient for forty days. The southern and western districts of the city are supplied from the waters of the Thames, the southern district consuming the largest of all portions of the city—e.g., 25.45 per cent.; the new River district is furnished from the River Lee, the Chadwell springs, wells in the Lee Valley, and the Thames, and the eastern district from the Lee River principally, to the extent of 69.05 per cent., and its remaining percentage from the Thames.

PRODUCTION OF PETROLEUM IN CANADA.

The following interesting information concerning the production of petroleum is given in the report on Economic Minerals and Mining Industries, recorded by Mr. J. McLeish, and issued by the Department of Mines, Ottawa:—"At the present time the principal oil fields in Canada are situated in the peninsula of south-western Ontario, between Lake Huron and Lake Erie. The first oil was found in Lambton County in 1862, and active production has been continued ever since. Until 1907, the Lambton County fields in which there has been about 11,000 producing wells were by far the largest producers; since then, several new districts have been opened up, the most prominent ones being the Tilbury district in Kent county and the Onondaga district in Brant County. The oil districts are all situated within an area underlain by Devonian strata, usually on an anticlinal axis, and the petroleum is largely obtained from horizons in the Onondaga formation at depths varying in the different localities. When the wells are first drilled, the natural pressure is usually sufficient to force the crude oil to the surface, sometimes producing what are known as gushers. After the flowing period, the oil has to be pumped. While some of the smaller districts became exhausted in a few years, many of the pools being only a few hundred feet wide and perhaps a quarter of a mile long, others have continued to furnish oil for a long period. Four refining companies are operating in Canada distilling about 10 million gallons of Canadian crude oil per year, but the greater part being distilled at these refineries is still being imported from the United States. The total production for Canada for the year 1912 was 243,336 barrels valued at $345,050. In New Brunswick, in the district lying 11 miles to the south of Moncton, oil is being pumped in small quantities from the holes which produce the gas of this district. Although the production so far is not large, drill holes are continually being sunk, and it is hoped that very shortly a stronger and more continuous yield will be the result. In Alberta, although oil has not been encountered in commercial quantities, prospecting for it is being carried on vigorously, and there is every probability that this province will be added to the list of producers at a very early date. In connection with the oil industry in Canada, mention should be made of the existence of extensive deposits of bituminous shales and tar sands. Beds of bituminous shales, as at present recognized, are found in Gaspe, New Brunswick and Nova Scotia. Those in New Brunswick are without question the most important. They occur in the counties of Albert and Westmorland and extend in an easterly and westerly direction over a distance of 40 miles. During the past 10 months extensive exploration, by means of diamond drilling and surface work, has demonstrated not only the quantity but the quality of these valuable deposits. It is anticipated that in the near future a plant, with a capacity for an initial daily treatment of 2,000 tons of shale, will yield approximately 80,000 gallons of crude oil per day. Tar sands are known to occur in Alberta along the Athabaska River for a distance of upwards of 100 miles north and south of Fort McMurray. Although the existence of these deposits has been recognized for many years, no steps have as yet been taken to accurately determine their possibilities."

The estimate of $1,500,000 as the net manufacturing profits of the Spanish River Pulp and Paper Mills for the current year will be noted for reference a year hence. The corresponding profits for the combined companies in the year ended June 30th were approximately $350,000, so an increase of something more than 300 per cent. is anticipated.

WATER WASTE IN CITIES.

Last week the subject of excessive waste was broached in these columns in connection with the water consumption of one of our Canadian cities. It is a subject that should have more attention in many cities and towns, as in some of them there appears to be little or no effort at conservation. It is not implied, of course, that the aim should be to have consumers economize in the legitimate use of water, but rather to show that cases are prevalent where, so long as there is water in the reservoir, the profligate waste goes on unchecked. Misjudgment in this respect has frequently caused alarm and danger.

Considering the fact that the majority of water supplies throughout the country have to be pumped once, and sometimes twice, that many of them are filtered, and some of them chemically treated, water should cease to be regarded "as free as air," as it is in reality a manufactured product with manufacturing costs accompanying it.

It is interesting to note the procedure in Philadelphia, not many years ago regarded as the most pronounced in water wasting of the larger cities. A year ago a water waste campaign was established. It was begun by securing an ordinance allowing the installation of water meters. This was followed by a Water Conservation Show, where meters and other water-saving appliances were exhibited. A large force of inspectors, under good supervision, began a house-to-house inspection, and during the year practically the entire city has been covered twice in this way. Hundreds of thousands of leaky fixtures were located and repaired.

An exhaustive campaign for the detection and repair of street leaks has been going on. This work is made possible largely through the use of the pitometer and the microphone, and is done for the most part between midnight and 4 a.m. The night flow in most districts is a good measure of unwarranted waste, and through the use of the microphone water running far below the surface can sometimes be distinctly heard, when the noise of daily traffic is absent.

By the elimination of undue waste of water, Philadelphia has added materially to its water pressure, both for fire and home purposes. That the campaign for its conservation has been successful is demonstrated by the reduced amount of water pumped. In West Philadelphia, where the work has been very thoroughly done, the daily pumpage has been reduced from 45-48 million gallons to 32-35 million gallons within a year. An interesting index of the smaller demand on the pumping stations is the fact that they are burning 3,000 tons less coal than for the corresponding month of last year.

PERMANENT HIGHWAYS URGED BY COUNTIES.

Following the two sessions recently held by the Public Roads and Highway Commission, at Ottawa and Belleville, a third sitting took place in Hamilton on Nov. 11th, which has undoubtedly added much to the body of information to form the basis for action toward a provincial system of road-making and maintenance on the most approved plan. The general feeling at the Hamilton meeting was that the main roads should be made provincial highways, to be constructed and maintained by the Provincial Government, under the supervision of a highways commission. It was recommended that the construction be of a permanent nature, suitable for present-day traffic

and the traffic that is likely to follow the construction of these permanent roadways.

In the matter of financing the construction of such provincial highways, it was recommended that the property benefited by such roads should be assessed 25 per cent. of the cost, to be spread over a reasonable number of years. The cities, towns and villages that are connected up with the provincial highways also to pay 25 per cent. of the cost, to be apportioned on the basis of population, the balance of 50 per cent. to be paid by the Provincial Government. The meeting, however, was strongly of the opinion that the Dominion Government should assist by paying a portion of this 50 per cent.

It was further urged that a reasonable tax be placed upon motor-driven vehicles in the Province, the proceeds of this tax to be used for the maintenance of Provincial roadways, this maintenance also to be under the supervision of the government highways commission.

Regarding the secondary roads and feeders to the Provincial highways, a more comprehensive system was urged. These roads should be county roads, and financed as at present by the Government paying one-third of the cost, the counties to be assisted by the commission in the selection of roads best adapted for feeders.

Such opinions were embodied in a resolution jointly presented to the Commission by the Board of Trade, the Manufacturers' Association and the Automobile Club. Unlimited confidence seems to be reposed in the ability of the Provincial authorities to make and maintain roads that will bring the producer and consumer more closely together for the benefit of the Province generally. It is the feeling among practically all counties that the responsibility of such an undertaking is of so great an extent that the Provincial Government should assume a portion of it, if the roads of older Ontario are to meet with material improvement.

MUNICIPAL CONTROL OF PUBLIC UTILITIES.

The National Municipal League, which held its 19th annual meeting in Toronto last week, entered into a thorough discussion of municipal enterprise, and municipal government, and closed with a very important paper by Dr. Delos F. Wilcox, of New York, on the "Rights of Local Municipal Control as Against State or Provincial Control of Public Utilities." The speaker drew his arguments from the experiences of nearly every important city in the United States. Dr. Wilcox is a prominent authority upon public utilities, having been recently associated with the Public Utilities Commission of New York, as an expert on franchises.

Local control, according to Dr. Wilcox, is becoming more and more essential every year to the successful administration of the affairs of cities and larger towns. He believes that in America there is a tendency towards too great a centralization in the control of public utilities, and that certain features of exclusive state regulation tend to make the municipalization of utilities more difficult.

After reviewing the arguments in favor of State control, in which he showed how local telephone and electric railway systems often overlap municipal boundaries and even transcend State boundaries and how the development of hydro-electric power has necessitated wide fields of distribution, thus almost demanding State control, Dr. Wilcox showed that most public utilities are primarily urban in character and are developed primarily in relation to one or more urban centres. It was necessary to localize the control of these, therefore, as much as possible. The more powerful private corporations operating public utilities become, and the more widespread their services, the more important it is that they should be directly answerable to the local communities which they serve.

With regard to the control and financing of the extensions of public utilities in a city, Dr. Wilcox said: "I believe that a public utility within a given urban community is a natural monopoly, and that one of the first and essential obligations of such a monopoly is to extend its services to meet all the legitimate needs of the community. In practically every city," he continued, "where there is a street railway situation, one of the greatest difficulties is found in the absence of public control in the matter of extension. There is nothing which the people of a growing city so insistently demand as extensions of street railway systems, and there is no point where the street railways more strenuously refuse to recognize public initiative and control than in the building of additional lines. A few cities have covered the problem of extensions more or less successfully in their franchise contracts. This is notably the case in Chicago and Cleveland, and the principle is recognized in the new subway contracts in New York."

CONVENTION—AMERICAN ROAD BUILDERS' ASSOCIATION.

In our issue of Oct. 2nd, (page 537) we presented the tentative programme of the Tenth Annual Convention of the American Road Builders' Association, to open in Philadelphia on December 9th.

Owing to a few important changes that have been made in the programme, it is published herewith as now arranged. It deals with twelve important subjects introduced by papers by the leading highway commissioners, engineers and experts. Discussions are being previously prepared.

Subject A.—Organization.

1. Highway Officials, Their Duties and Powers.

2. Division of Expense, Responsibility and Authority Between Nation, State, County and Town.

3. The Relation to Each Other of the Contractor, Engineer and Inspector.

4. Details of Arrangements for the Use of Convict Labor.

Subject B.—Construction.

1. Determination of the Amount of Realignment, Grading and Drainage to Be Done in Connection With Road Improvement.

2. Factors Governing a Proper Selection of Road or Street Pavement.

3. Details of the Construction of the Various Kinds of Roads and Pavements.

Ten-minute papers on the following subjects: Earth Roads; Sand-Clay Roads; Gravel Roads; Water-Bound Macadam; Bituminous Macadam and Bituminous Concrete; Brick; Concrete; Wood; Granite and Asphalt Block; Sheet Asphalt.

4. Unit Price and Lump Sum Contracts and Percentage Work.

5. The Testing of Material for Road and Street Construction.

Subject C.—Maintenance.

1. Sub-Organization for Securing Efficient Maintenance.

2. General Methods of Repairs and Renewals.

3. Bituminous Surface Treatment and Dust Prevention.

Among those who are to take part in the proceedings are the following: Chas. J. Bennett, State Highway Commissioner of Connecticut; E. M. Bigelow, State Highway Commissioner of Pennsylvania; A. H. Blanchard, Professor of Highway Engineering, Columbia University, New York, N.Y.; Henry L. Bowlby, State Highway Engineer of Oregon; Frank W. Buffum, State Highway Commissioner of Missouri; John N. Carlisle, State Highway Commissioner of New York; Wm. H. Connell, Chief, Bureau of Highways and Street Cleaning, Philadelphia, Pa.; Geo. W. Cooley, State Engineer of Minnesota; F. L. Cranford, Road Contractor, Brooklyn, N.Y.; Major W. W. Crosby, Chief Engineer, Maryland Geological Survey; A. W. Dean, Chief Engineer, Massachusetts Highway Commission; Fred E. Ellis, Road Contractor, Peabody, Mass.; A. B. Fletcher, State Highway Engineer of California; S. D. Foster, Chief Engineer, Pennsylvania State Highway Department; R. B. Gage, Chemist, State Highway Department of New Jersey; John S. Gillespie, Road Commissioner of Allegheny County, Pa.; L. R. Grabill, Superintendent of Suburban Roads, District of Columbia; H. C. Hill, Engineer, Lane Construction Co., Meriden, Conn.; A. R. Hirst, State Highway Engineer of Wisconsin; Prevost Hubbard, Consulting Chemist, Institute of Industrial Research, Washington, D.C.; Jos. W. Hunter, Deputy Commissioner, Bureau of Township Highways, Pennsylvania State Highway Department; A. N. Johnson, State Highway Engineer of Illinois; C. A. Kenyon, President, Indiana Good Roads Association; Nelson P. Lewis, Chief Engineer, Board of Estimate and Apportionment, New York, N.Y.; James H. MacDonald, former State Highway Commissioner of Connecticut; T. H. MacDonald, State Highway Engineer of Iowa; W. A. McLean, Chief Engineer of Highways and Commissioner of the Ontario Public Roads and Highways Commission, Toronto, Ont., Canada; R. A. Meeker, State Highway Engineer of New Jersey; Harold Parker, Vice-President, Hassam Paving Co., Worcester, Mass.; Robert J. Potts, Professor of Highway Engineering, Agricultural and Mechanical College of Texas, College Station, Tex.; Dr. Joseph Hyde Pratt, State Geologist of North Carolina; Jean de Pulligny, Engineer-in-Chief, Board of Public Works of France, and Director of the French Mission of Engineers to the United States; John J. Ryan, Secretary, Road Builders' Association, Albany, N.Y.; Frank F. Rogers, State Highway Commissioner of Michigan; Chas. W. Ross, Street Commissioner, Newton, Mass.; Paul D. Sargent, Chief Engineer, Maine State Highway Commission; Herman H. Schmidt, Chief Engineer, Bureau of Highways, Borough of Brooklyn, New York, N.Y.; Henry G. Shirley, Chief Engineer, Maryland State Roads Commission; Francis P. Smith, Consulting Chemist and Paving Engineer, New York, N.Y.; Robert C. Terrell, Commissioner of Public Roads of Kentucky; Geo. W. Tillson, Consulting Engineer to the President of the Borough of Brooklyn, New York, N.Y.; Wm. D. Uhler, Assistant Engineer, Bureau of Highways and Street Cleaning, Philadelphia, Pa.; P. St. J. Wilson, State Highway Commissioner of Virginia.

EFFECT OF HIGH PRESSURES.

CURIOUS and unlooked-for manifestations have of late been observed from the application of very high pressure. It used to be considered that heat was the only medium which would separate compound substances into their simple elements, but it has now been found that pressure is equally effective and more convenient in some respects. Salts decompose spontaneously into their component acid and metals, water yields its elementary gases, and heat consolidates into coal.

The application of very high pressures seems to be producing a positive revolution in the chemical industry, and is briefly referred to in Railway and Locomotive Engineering. Only a short time ago, the report circulated that Haber had succeeded in causing elementary nitrogen and hydrogen to react at a pressure of 300 atmospheres (4,410 pounds) and at temperatures varying between 900 and 1,080 degrees F. A remarkable reaction belonging to this category was likewise discovered by Ipatiew, who succeeded in precipitating metals from their sale solutions by hydration under high pressure. Thus, starting with cupric sulphate, he obtained finely distributed copper and sulphuric acid. There is another interesting reaction in the decomposition of water under high pressure and at high temperatures in the presence of a metal, as, for instance, iron, which binds the oxygen separated. At the same time, hydrogen of very high purity is yielded. This new method of producing pure hydrogen is of especial interest at the present time, since this gas is used for many technical purposes in various departments. Among the various modes of production that have been announced of late, the new method is probably the cheapest. The production of artificial coal under high pressure is also one of the recent inventions. Cellulose or peat is heated up with water to 612 degrees F., under a pressure of more than 100 atmospheres (1,470 pounds) in apparatus especially constructed for the purpose, the resultant being a product identical with mineral coal, both from a physical and a chemical point of view. At 558 degrees F. the process requires 80 hours, at 612 degrees F. only 8 hours are necessary for the transformation.

MOTOR TRAFFIC IN CANADA.

Over 12,400 more motor vehicles were in use in the Dominion on November 1st than at the end of last year, according the figures compiled by the Automobile Club of Canada. The following are the totals for each of the provinces, including private and commercial vehicles and motor cycles:—

	1912.	1913.
Quebec	3,597	4,706
Ontario	11,939	15,255
New Brunswick	289	789
Manitoba	3,043	5,016
British Columbia	4,666	7,044
Nova Scotia	867	1,300
P. E. Island	...	...
Saskatchewan	3,742	6,513
Alberta	2,835	3,640
Yukon	5	15

It is rather remarkable that the largest gains among the motor vehicle using provinces were made at the two ends of the continent—in New Brunswick and the Yukon, where the increases were over 300 per cent.

STATICAL ANALYSIS OF REINFORCED CONCRETE ARCH BRIDGE

DESCRIPTION OF A RAILWAY BRIDGE OF SPECIAL DESIGN — AN ANALYSIS OF ITS STRESSES AND DEFLECTIONS — RESULTS OF TEST LOADING

By V. J. ELMONT, B. Sc., A.M. Can. Soc. C.E.

THIS bridge carries a single-track railway over the River Werra. In order to allow for future navigation it was found necessary to bridge the river in one span of 174 feet.

As will be seen in the illustrations (Figs. 1, 2 and 3) the bridge has two arches, arranged above the bridge floor; they are calculated and constructed as arches without hinges, for which kind of structure the soil (coarse gravel) was very well suited, the maximum pressure on it being only 5,000 to 6,000 lbs. per sq. ft. Above the clearance line of the cars the arches are stiffened sideways by T-shaped struts (see Figs. 2 and 4) which, together with the arches, form a strong truss. The free space between the arches is 14′ 5″, the depth of the arches at the crown is 5′ 3″ and at the springing line 8′ 2″; the rise is 34 feet.

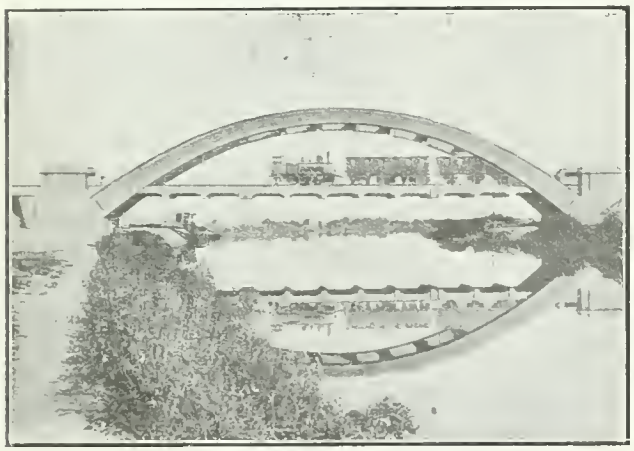

Fig. 1.

The bridge floor is suspended from the arches by means of rods, carefully anchored in the arches and floor beams. The slab which forms the direct support for the ballast, in which the cross-ties for the rails are embedded, is 5½″ thick and is carried by four longitudinal beams, which again rest on the floor beams spaced 13′ 7″ centre to centre. These are 2′ 7″ wide in the middle, tapering to 1′ 7″. This form was adopted in accordance with the requirements of the specification, viz., that the actual tension stress in the concrete should not exceed 275 lbs. per sq. in.

In order to avoid stresses in the floor produced by variations of temperature, it is divided into three parts, the two end sections being rigidly connected with the arches, while the middle section hangs freely and engages with the end sections by means of indentations; the floor will thus act as a horizontal cantilever girder for wind forces, having a simply supported part at the middle resting against two cantilever arms at the sides.

The abutments (Fig. 5) are formed by widening the arches below the bridge floor, and connecting them by a slab towards the river.

The falsework used in the construction of the bridge was given an overheight at the crown of the arches of 2″, diminishing towards the ends. It was found that the settlement of the falsework during the concreting amounted to 1⅜″ at the crown, and when the falsework was removed after the concrete had hardened for five weeks a further settlement of 7/16″ took place.

Fig. 2.

Statical Analysis.—The following maximum stresses were allowed: Concrete in compression, without regard to temperature stresses, 500 lbs. per sq. in.; concrete in compression, including temperature stresses, 650 lbs. per sq. in.; concrete in tension, including temperature stresses, 275 lbs. per sq. in.; steel in tension, including temperature stresses, 14,000 lbs. per sq. in. The calculation of the bridge floor does not include any special features.

The depth of the arches was first computed by repeated approximate figuring to d_c = 5′ 3″ at the crown and d_s = 8′ 2″ at the springing line, with a width of 3′ 7″, and then tested by the exact formulæ for arches without hinges. The dimension d_x for the interspacing point with the abscissa x measured from the crown was taken from the formula

$$d_x = d_0 + 4\left(\frac{x}{l}\right)^2\left(d_s - d_0\right),$$

where l is the theoretical span; it has been proved that a good variation of the cross sections is obtained by this equation.

The form of the centre line of the arches follows a funicular polygon to the dead load of the structure, which can be calculated from the above expression for d_x. The differential equation for the centre line is $\frac{d^2y}{dx^2} = \frac{g}{H}$, where g is the load per unit length and H the horizontal pressure. By integration

$$\frac{dy}{dx} = \frac{1}{H}\int g\,dx + C; \quad \left(\frac{dy}{dx} = 0, \text{ giving } x = 0 \text{ and } C = 0\right)$$

$$y = \frac{1}{H}\int dx \int g\,dx + C_1;$$
